

## AN INQUIRY INTO THE EPIDEMIOLOGY OF PEMPHIGUS NEONATORUM

BY

V. D. ALLISON, M.D., D.P.H.

AND

BETTY C. HOBBS, B.Sc., Ph.D., Dip.Bact.

(From the Emergency Public Health Laboratory, Institute of Preventive Medicine, Cardiff)

In recent years there has been a considerable increase in the incidence of pemphigus neonatorum, especially in nurseries in maternity hospitals and units. Cases and outbreaks have in the main been mild, with a very low mortality, but this does not lessen the administrative problems of isolation, quarantine, and ward closure. The rise in incidence of infection due to *Staph. pyogenes* not only in infants but also in nursing mothers, and bacteriological studies of infection in surgical operation wounds, war wounds, and industrial dermatitis, have led to an increased interest in the epidemiology of staphylococcal infections in general. The study of the epidemiology of pemphigus neonatorum and of other staphylococcal infections is rendered difficult by the ubiquity of the causative organism, and it is obvious that the application of any method whereby strains of *Staph. pyogenes* can be differentiated into types must inevitably lead, as in the case of *Str. pyogenes*, *Str. pneumoniae*, the typhoid bacillus, and *Salmonella* organisms, to more accurate knowledge of the sources and paths of spread of infection.

The most generally accepted criterion of actual or potential pathogenicity of staphylococci at present is the ability to produce coagulase, and as staphylococci may be golden, yellow, off-white, or white we have applied the term *Staphylococcus pyogenes* to coagulase-positive strains regardless of pigment production. The first acceptable differentiation of *Staph. pyogenes* into types was described by Cowan (1939), using a slide-agglutination technique whereby most strains of *Staph. pyogenes* were found to fall into three types and an atypical group among which he tentatively recognized five subtypes (personal communication). Differentiation of the subtypes is often difficult, as they are not always clear-cut, and a considerable amount of cross-reaction may occur owing to the presence of common antigens. In 1940 Christie and Keogh, using the same technique, succeeded in differentiating nine types, including Cowan's original three; their observations were based on reactions with absorbed and unabsorbed sera, and the organisms were classified according to the presence of major and minor agglutinogens, but they did not find it possible to eliminate the considerable antigenic overlap between different strains. A further development occurred in 1945, when Wilson and Atkinson described a method of differentiating types among *Staph. pyogenes* by means of bacteriophage action, evolved from the original observations of R. T. Fisk (1942) and

R. T. Fisk and Mordvin (1944); by this method they were able to recognize 21 types or subtypes and to apply the technique successfully to the investigation of several outbreaks of staphylococcal infection, in particular food-poisoning due to staphylococcal enterotoxin.

In the course of investigations to confirm and extend the work of Cowan and of Christie and Keogh, and to explore the possibility of obtaining more clear-cut results by agglutination methods, we were called upon to investigate outbreaks of staphylococcal infection causing pemphigus neonatorum and breast abscess in nursing mothers (Hobbs, 1944), food-poisoning due to staphylococcal enterotoxin (Murphy and Edward, 1944), and cases of sycosis barbae (Hobbs, Carruthers, and Gough, 1947). This provided an opportunity for testing experimental sera and for carrying out investigations on the epidemiology of staphylococcal infections, in particular pemphigus neonatorum.

In November, 1943, we were asked to investigate an outbreak of pemphigus neonatorum, affecting eight infants, in the main nursery of the maternity unit, City Lodge Hospital, Cardiff. This marked the beginning of a series of observations on the epidemiology of pemphigus neonatorum in the unit, which continued uninterruptedly for two years till November, 1945. During this period 2,719 infants were born in or admitted to the unit, of which 111 (4.1%) developed pemphigus neonatorum; all strains of *Staph. pyogenes* isolated from these patients were investigated serologically.

In addition, there occurred during the period of investigation 25 cases of staphylococcal conjunctivitis ("sticky eye"), either alone or associated with pemphigus neonatorum; cultures were taken from the infected conjunctivae for bacteriological and serological examination.

## Procedure and Technique

(a) *Collection of Specimens.*—The specimens examined came from the lesions, nose, eyes, and occasionally umbilicus of infected infants, from the nose of healthy infant in infected nurseries, from likely sources of infection such as the nose, throat, and skin of infants' mothers, nursing, domestic, and medical staff, from air and dust in the nursery, and from infants' blankets and gowns. New patients were visited as early as possible in order to collect fluid from intact bullae by aseptic puncture with sterile Pasteur pipettes drawn out to a fine capillary. If the lesions were already open and discharging, swabs

were taken from the exudate after initial cleansing with sterile gauze. Nasal and eye swabs for infants were made from a fine pliable copper wire with a very small pyriform pledget of cotton-wool. Specimens for culture from skin were taken from the thumb, the terminal phalanges of the index and middle fingers, and the palmar and dorsal surfaces of the hand with swabs previously moistened with quarter-strength Ringer solution. Dust samples consisted of floor sweepings, which were collected in sterile test-tubes and shaken up in quarter-strength Ringer solution; cultures were made from tenfold dilutions. For air-sampling blood-agar plates were exposed for one to three hours in the air of the ward during both quiet periods and periods of greatest activity. Blankets and infants' gowns were tested by soaking two small areas of about 12 sq. in. (75 sq. cm.) of each article in nutrient broth, cultures being made from the broth and from dilutions of the broth.

(b) *Laboratory Procedures.*—Agar plates containing 10% horse blood were the basic medium used for the culture and isolation of strains of *Staph. pyogenes*, but specimens from lesions were often cultured also on gentian violet (1/500,000) blood agar, especially if the presence of *Str. pyogenes* was suspected. Swabs still moist were inoculated direct on to blood-agar plates, but any which appeared to be dry were moistened with broth or quarter-strength Ringer solution. An ideal procedure was to incubate the swab in broth after inoculation of the plates. The broth culture after 18 hours' incubation was used for the tube-coagulase test (Gillespie, 1943), and if the direct plate showed no staphylococci the enrichment broth was plated out on to blood agar. By this method small numbers of staphylococci often missed by direct plating were isolated in almost pure culture. Following overnight incubation of the direct plate at 37° C. observations were made on the amount of growth, the types of organisms, and the proportion of colonies of *Staph. pyogenes*. From all cultures showing the presence of staphylococci at least two colonies were tested for their ability to produce coagulase by the slide-coagulase test introduced by Cadness-Graves *et al.* (1943), using human plasma. Pigmented strains which were coagulase-negative by the slide technique were re-tested by the tube method (A. Fisk, 1940). At least two coagulase-positive colonies from each culture were sub-cultured for serological typing. It was found advisable to

ave the blood-agar plates on the bench for a few days to e full development of pigmentation and colony gy. By so doing differences between types of colony more obvious, and such differences were frequently to correspond with different serological types, and often than one type was present on a plate. Serological typing carried out by means of the slide-agglutination technique ribed by Cowan (1939), using crude and absorbed sera m rabbits inoculated with vaccines prepared from Cowan's iginal three strains and from strains of additional types described by Christie and Keogh (1940). Agglutinating sera were also prepared against a number of freshly isolated strains which did not appear to fit into any of the hitherto identified types; these strains were cultured from various staphylococcal lesions during the course of the investigation. Many of the strains of *Staph. pyogenes* type Ib isolated from lesions during the second outbreak of pemphigus were typed by the bacteriophage method at the Public Health Laboratory, Oxford, and were regularly lysed by the same phage filtrates.

#### Prevalence of Pemphigus Neonatorum during the Period of Investigation

The maternity unit was housed in a 2-story block and consisted of a main nursery (Nursery 10) with 32 cots (later reduced to 16), a nursery for premature infants (10 cots), another 10-cot nursery, and five isolation nurseries (10 cots). In three of the six wards mothers and infants were nursed together. The unit had maximum accommodation for about 90 infants with their mothers, including isolation cases.

Prior to November, 1943, cases of pemphigus neonatorum in the unit had been rare, and had occurred singly and sporadically. Between November, 1943, and October, 1945, 132 cases of pemphigus neonatorum and staphylococcal

conjunctivitis occurred in the unit, and their distribution in the various wards and nurseries is shown in Table 1. It will be seen that 93 cases (70.5%) occurred in infants in Nursery 10, attached to Wards 10 and 11, while 29 cases (22%) occurred in infants in Wards 8 and 9; there were only two cases in premature infants. It is also to be noted

that all 21 cases of staphylococcal conjunctivitis and three of the four cases of combined pemphigus and staphylococcal conjunctivitis occurred in Wards 8 and 9 and Nursery 10. As over 70% of the cases were among infants in this nursery the epidemiological investigations carried out were centred round it.

The present investigation began when three cases of pemphigus occurring in Nursery 10 were reported to the laboratory during the first week of November, 1943, and the unit was visited to take specimens for bacteriological examination. During the two succeeding weeks five further cases of pemphigus developed in this nursery, and as serological methods of identifying the infecting strains of *Staph. pyogenes* had already proved successful in tracing the source of a small outbreak of pemphigus neonatorum in a private nursing home it was decided to widen the scope of the inquiry in order to discover the source of infection and the mode of spread.

#### Investigations and Results

Coagulase-positive staphylococci, usually in pure culture, were isolated from the lesion of every case investigated, including both pemphigus and "sticky eye." Swabs from the lesions of many cases were examined on repeated occasions, and in infants with multiple lesions sometimes several swabs were taken from different infected areas of the body. All the strains were subjected to serological examination, and the infecting organism was typed in all but one of the 132 cases.

#### Distribution of Serological Types in the Lesions of Infected Infants

Fig. 1 shows the distribution month by month of the serological types of *Staph. pyogenes* isolated from all the cases in the maternity unit during the period of investigation. The total number of infants born in the maternity unit month by month during the period is also shown, and varied from 84 to 144, with a mean of 113.7. The number of cases of pemphigus and staphylococcal conjunctivitis per month varied from 0 to 22, with a mean of 5.5. In broad outline the chart shows a small sharp outbreak due to *Staph. pyogenes* type I which occurred early in November, 1943 (8 cases: 6 type I). This was followed by an outbreak due to type Ib which began in January, 1944, and continued with varying intermissions and recrudescences until May, 1945 (119 cases: 101 type Ib). Following an intermission of three months during which no cases occurred, there were indications of a third outbreak starting early in October, 1945 (5 cases: 4 type I), just as the investigation had to be terminated.

The first outbreak involved eight infants, all in Nursery 10, who were infected over a period of two weeks in November, 1943. *Staph. pyogenes* type I was isolated from the lesion of six infants; of the remaining two, one was infected with *Staph.*

*pyogenes* type I/II and the other with type IIIc. The latter infant was later reported to have been discharged from the unit with no evidence of pemphigus and to have been brought back one week later suffering from pemphigus and staphylococcal conjunctivitis. Type IIIc was also isolated from pus from the infected eyes and from the nose. During December no cases

FIG. 1.—The serological types of *Staph. pyogenes* causing pemphigus neonatorum and staphylococcal conjunctivitis among infants in a large maternity unit month by month from November, 1943, to October, 1945.

of pemphigus occurred, but in January, 1944, there were five cases, in two of which infection was due to *Staph. pyogenes* type I. From the three remaining cases *Staph. pyogenes* type Ib was isolated, and this type became the prevailing cause of pemphigus neonatorum in the unit during the remainder of the period of investigation. In February there were ten cases of pemphigus, all due to type Ib, and seven cases of staphylococcal conjunctivitis, of which four were caused by type Ib. During March no cases of pemphigus occurred in Nursery 10, but there were seven cases of staphylococcal conjunctivitis, of which four were due to type Ib, two to type I, and one to type Ia. A sharp rise in the incidence of pemphigus took place in May, mainly affecting Nursery 10 in which 21 cases occurred, 20 due to type Ib and one to type I. The one case of staphylococcal conjunctivitis in May was due to type IIIc. Following this outbreak in May, Nursery 10 was closed for a few days at the beginning of July and was thoroughly washed and cleansed. The nursery was reopened under less crowded conditions and there were no further cases of pemphigus in it in July, but six occurred during August and September, all due to type Ib. A further rise in incidence in this nursery took place between October and December, when type Ib caused 17 cases of pemphigus, one case of pemphigus and conjunctivitis, and two cases of conjunctivitis alone. The next five months produced nine cases, all due to type Ib, of which seven occurred in Nursery 10; but no more cases of staphylococcal conjunctivitis were observed up to the end of the investigation. There were no cases of pemphigus during June, July, and August, 1945, but in September there was one case due to type I. When the investigation was terminated in October there had been three more cases in Nursery 10 all due to type I.

Table II gives the numbers of cases of pemphigus and staphylococcal conjunctivitis which occurred throughout the investigation in the various nurseries and wards, and also shows the type distribution of the strains of *Staph. pyogenes* isolated from the lesions. It demonstrates, as already pointed out, that

P = Pemphigus neonatorum. C = Staphylococcal conjunctivitis.

type Ib, isolated from 102 (77.3%) of the 132 cases, was responsible for the great majority of the infections. It may also be noted that 73 (68.2%) of 107 cases of pemphigus and 17 out of 21 cases of staphylococcal conjunctivitis occurred in Nursery 10; between 50 and 60% of the infants born in the unit occupied Nursery 10.

#### Staphylococcal Conjunctivitis

A study of Table II shows that 87 (81.3%) out of 107 cases of pemphigus were caused by type Ib, and only 12 (57.1%) out of 21 cases of staphylococcal conjunctivitis were due to the same type; three out of four cases of combined pemphigus and conjunctivitis were due to type Ib. It would appear, therefore, that in an outbreak of pemphigus due to a particular serological type of *Staph. pyogenes* associated cases of conjunctivitis due to the epidemic type may occur, but there may also arise sporadic cases of conjunctivitis due to other serological types of *Staph. pyogenes* not prevalent as the cause of pemphigus, or indeed in the absence of pemphigus.

Swabs were taken from both eye and nose of nine cases of conjunctivitis, and seven showed the same type in eye and nose, the types being different in the remaining two. Swabs from four patients with coincident pemphigus and conjunctivitis yielded the same type from eye and lesion in each case, and in two cases from which nasal swabs were also taken the infecting type was found in the nose as well. When pemphigus and conjunctivitis occurred in the same patient, therefore, the double infection was caused by the same serological type of *Staph. pyogenes*. Also when conjunctivitis alone occurred the same type of *Staph. pyogenes* was present in the infected eyes and in the nose of a high proportion of cases.

#### Serological Types of *Staph. pyogenes* Isolated from Nursery Staff

Swabs were taken from the noses, hands, and occasionally the throats of the nursery, domestic, and medical staffs of the unit three times during the course of the investigation (Table III). The first of these occasions was in November, 1943, two days after starting the investigation of the first outbreak of pemphigus neonatorum in Nursery 10. Nose, throat, and hand swabs were taken from 15 members of the medical and nursing staff of the infants' nursery, and 10 (66.7%) were found to be harbouring *Staph. pyogenes* in one or more of the three sites. Four carried the epidemic type I, two harboured type IIIb, two type IIIc, and one each types Ia and Ib, all in the nose. *Staph. pyogenes* was isolated from the hands of seven members of the nursing staff, and all the strains belonged to the same serological types as were present in the noses of the individuals.

The second swabbing of the staff took place in February, 1944, when cases in the second outbreak due to *Staph. pyogenes* type Ib were increasing in number. Fig. 1 shows that the peak of this outbreak was reached in May, 1944. Nose, throat, and hand swabs were taken from 40 persons, including doctors, sisters, nurses, pupil midwives, and ward cleaners—the entire

\* One nurse (6.7%) harboured *Staph. pyogenes* type Ib in her nose. † Two nurses (5.0%) harboured *Staph. pyogenes* type I in the nose. ‡ Two nurses (4.2%) harboured *Staph. pyogenes* type Ib in the nose.

staff of wards and Nurseries 8, 9, 10, and 11. It appeared that most of the junior nursing staff had altered since the previous swabbing in November, 1943, as a regular change-over of pupil midwives took place every three months. Of 40 persons 29 (72.5%) harboured *Staph. pyogenes*; 28 of these were nasal carriers and one had a positive throat culture only. The epidemic strain, type Ib, was harboured by 12 persons (30%), type Ia by six persons, types IIIa and IIIb by three persons each, type I (5%) by two persons, type IIc by one person, while two persons carried unidentified types. Ten members of the staff had *Staph. pyogenes* in both nose and throat, and in eight the organisms in both sites were of the same type. Eleven persons showed *Staph. pyogenes* both in the nose and on the hands, and in nine instances the types were the same in both sites.

It was apparent that the percentage of the staff harbouring the first epidemic strain, type I, had declined from 26.7% to 5%, and that the second epidemic, type Ib, was now prevalent to a degree (30%) shown formerly by type I; in the first swabbing type Ib was found present in the nose of only one nurse (6.7%). These findings suggested that a high carrier rate among the staff of an infective strain of *Staph. pyogenes* would render the infant population of a nursery highly exposed to infection by that strain, and be followed by the appearance of clinical cases of pemphigus neonatorum and of staphylococcal conjunctivitis. An opportunity to test this hypothesis was provided by the occurrence of a small number of cases of pemphigus due to *Staph. pyogenes* type I in September and October, 1945. Following three isolated cases caused by type Ib in March, April, and May there had been a lull in the incidence of pemphigus throughout the unit during June, July, and August. Alterations in the technique of routine procedures that may have been responsible for this decline in cases are described in a later section. At the beginning of October, 1945, nasal and hand swabs were taken from 48 members of the maternity staff, more than half of whom were pupil midwives who had recently joined the staff and had not been swabbed previously; 33 (68.8%) were found to be harbouring *Staph. pyogenes* in the nose and 10 on the hands. Eighteen of the nasal carriers carried type I, eight harboured type IIIb, three type I/II, two type Ib, and two type II. Again the most prevalent type present in the noses of the staff was that giving rise to the fresh cases of pemphigus in the nursery. Of the total staff 18 (37.5%) harboured type I, and only two individuals (4.2%) carried type Ib, which had been responsible for cases throughout 1944 and the early part of 1945 and which was present in the noses of 30% of the staff in February, 1944. The first two swabbings of the staff had been carried out during the height of outbreaks of pemphigus, and it was impossible to decide whether the high nasal carrier rate of the epidemic strain was a cause or a consequence of the outbreak. The third swabbing, however, was carried out after a case due to a different type had occurred, following a period of three months during which there had been no cases of pemphigus or staphylococcal conjunctivitis. The presence of a high proportion of

nasal carriers of the infecting type among the staff at this early stage strongly suggests that a build-up of nasal carriers of a potentially infective strain occurs among the staff before the appearance of cases of pemphigus.

Twelve members of the nursery staff were swabbed on two or more occasions. Nasal swabs from five either showed non-epidemic types of *Staph. pyogenes* or were negative. Of the remaining seven, four harboured the prevalent epidemic type once, while the remaining three yielded the prevalent epidemic type each time they were swabbed. The numbers are too small for any deductions to be drawn regarding the frequency of change of serological type of *Staph. pyogenes* in the nose in relation to the prevalent epidemic type.

#### *Staph. pyogenes* in Noses of Healthy Infants in the Infected Nursery

In addition to swabbing the staff, nasal swabs were taken from all the healthy infants in Nursery 10 on two occasions (Table III). First in November, 1943, at the time of the outbreak due to *Staph. pyogenes* type I, nasal swabs were taken from 32 healthy infants in the nursery; 28 (87.5%) were found to be harbouring *Staph. pyogenes* and 11 (34.4%) carried the epidemic type I and were free from clinical infection. Type Ia was isolated from six infants, type Ib from three infants, and type II from two infants, while 13 strains could not at that time be typed. Seven of the infants harboured more than one serological type of *Staph. pyogenes*. The infants harbouring type I were scattered throughout the nursery and there was no concentration of infants in neighbouring cots showing the same serological type in their noses.

When, in October, 1945, after a period of three months' freedom from infection, cases of pemphigus due to *Staph. pyogenes* type I began to appear in Nursery 10, nasal swabs were again taken from all of 18 infants in the nursery. Swabs from five of the infants, ranging in age from 5 hours to 2 days, failed to yield staphylococci; of the remaining 13 infants, aged from 4 days to 2 months, 11 (61.1%) were heavy carriers of *Staph. pyogenes*. The types were fairly evenly distributed, no single type being predominant, and the high nasal carrier rate of type I among the staff was not at this stage present among the infants.

#### *Staph. pyogenes* in the Nursery Air and Dust

Blood-agar plates were exposed in Nursery 10 on two occasions—first during the outbreak of pemphigus in November, 1943, and again in October, 1945. On the first occasion five plates were exposed at cot level in different parts of the nursery from 2 to 5 a.m. and a second series from 7 to 10 a.m., periods of least and greatest activity respectively in the nursery. A total of approximately 3,000 colonies, representing bacteria-containing particles, were counted on plates exposed from 2 to 5 a.m. Plates exposed from 7 to 10 a.m. were too overcrowded for counting. The organisms on the plates were predominantly saprophytic cocci and bacilli, but *Staph. pyogenes* was present in small numbers. Of three colonies of *Staph.*

*pyogenes* subcultured for examination two were identified as type I. The second exposure of plates in the nursery in October, 1945, yielded approximately 2,000 colonies during the early morning period and approximately 10,000 colonies during the active period between 7 and 10 a.m. Again *Staph. pyogenes* was present only in small numbers, but type I, which was at that time the cause of pemphigus, was identified on plates from four different sites.

It was evident, therefore, that the epidemic strain of *Staph. pyogenes* was present in the ward air during both periods of exposure, but it was not possible from these investigations to estimate to what degree, although it appeared to be low.

Two samples of dust from the floor of Nursery 10 were examined in November, 1943. The samples were collected into sterile jars from the routine morning sweepings. Cultures yielded large numbers of organisms, mainly saprophytic; but *Staph. pyogenes* was present in considerable numbers in one sample, while the other yielded scanty colonies. Of 18 colonies of *Staph. pyogenes* examined serologically five were identified as type I, four as type IIIc, one as type Ib, while the remaining eight could not be typed. The epidemic type I therefore represented 28% of a random sampling of *Staph. pyogenes* in the floor dust of the nursery; the remaining identified strains belonged to types which were found in the noses of members of the nursery staff and of healthy infants in the nursery.

#### *Staph. pyogenes* in Infants' Blankets and Gowns

*Staph. pyogenes* was isolated from five out of six blankets from cots in Nursery 10 in November, 1943; type I was found on one blanket and types Ib, II, IIIb, and IIIc on the others. One blanket was re-examined after laundering, and *Staph. pyogenes* type I was isolated from nutrient broth in which part of the blanket had been soaked and also by shaking the blanket over exposed blood-agar plates. Two flannel gowns belonging to infants in Nursery 10 were examined after laundering; one gown yielded *Staph. pyogenes* type IIIb and an untypable strain, while no staphylococci were isolated from the other.

Table III gives a summary of the results of examinations of cultures from material taken in relation to the three outbreaks of pemphigus neonatorum in Nursery 10. It shows the regularity with which the epidemic types were found in the noses of a high percentage of the nursery staff, and elsewhere in the infants' environment, and suggests that widespread distribution of an infecting strain in the nursery environment may bear a causal relationship to the onset of an outbreak. Members of the staff swabbed during the second and third outbreaks included those engaged on nursing duties in other nurseries and wards of the unit, especially Ward and Nursery 8/9, in which 23 out of 24 cases of pemphigus and three out of four cases of staphylococcal conjunctivitis were caused by *Staph. pyogenes* type Ib.

#### Distribution of Infecting Types of *Staph. pyogenes* in Eye, Nose, and Umbilicus of Infected Infants

During the course of the investigation swabs were taken from 102 of the 111 cases of pemphigus neonatorum, not only from the lesions but also from other sites on the body, including the nose, eye, and umbilicus. Table IV shows the numbers of

TABLE IV.—Correlation Between Serological Types of *Staphylococcus pyogenes* Isolated from the Lesion, Eye, Nose, and Umbilicus of Cases of Pemphigus Neonatorum (Total Number of Cases Examined—102)

Sites	No. of Cases Examined	Same Serological Types		Different Serological Types

cases from which the various combinations of swabs were taken and the numbers and percentages of cases in which strains of

*Staph. pyogenes* were serologically identical or of different serological types. In general it was found that there was a remarkably high association between the serological types of *Staph. pyogenes* present in lesion and nose, lesion and eye, and lesion and umbilicus, with a lower but still notable association between the types when more than one site was swabbed in addition to the lesion. Findings, already quoted, indicated the ubiquity of the infecting strain in the infants' environment, and these figures show that the wide dispersal extends also to the infants' healthy skin, upper air-passages, and exposed mucous surfaces such as the conjunctivae.

#### Serological Types of *Staph. pyogenes* Isolated from Mothers of Infected Infants

Apart from the nursery staff, consisting of doctors, nurses, and ward-maids, the only persons with whom the infants came into contact were the mothers, during breast-feeding. It was therefore decided to investigate serologically the staphylococcal flora of a number of mothers as a potential and intimate source of infection.

Swabs from the nose, throat, and in a few cases samples of the breast milk were taken from mothers of infected infants to see what relationship, if any, the serological types of *Staph. pyogenes* isolated from the mother bore to the type isolated from the infant. Swabs from the infants were taken from the lesion and from some or all of the following sites—nose, eye, and umbilicus. Table V shows the results of the examination

† Small septic lesion on breast following infection in her infant.

of strains of *Staph. pyogenes* isolated from 15 infected infants and from their mothers. In only six instances—viz., Nos. 1, 3, 4, 10, 13, and 14—was the serological type of *Staph. pyogenes* causing the infection in the infant also isolated from the mother; five of the six mothers harboured the organism in the nose, and in one (Mrs. Co., No. 3) it was found only in the breast milk. In the case of Mrs. Jo. (No. 4) the organism was isolated from the nose, the throat, and from a septic finger which occurred after her infant became infected with pemphigus, so it seems likely that she was infected by her infant. A similar explanation may account for the septic lesion in the breast of Mrs. Pi. (No. 13). If these two are eliminated, or even if not, the correlation of infecting strains in mother and infant is low. These findings, taken in conjunction with the results of the bacteriological investigations in Nursery 10, lend weight to the view that infection was spread in the nursery and was not transmitted to the infants by their mothers.

### Discussion

The results of the serological identification of strains of *Staph. pyogenes* isolated from the lesions of 132 cases of pemphigus neonatorum and staphylococcal conjunctivitis occurring in a large maternity unit over a period of two years show that there were three separate outbreaks, each due to a distinct serological type of *Staph. pyogenes*. The organisms causing the outbreaks were isolated not only from lesions but also from the eyes and noses of a large proportion of infected infants, from the noses of healthy infants in the same nursery, and from the noses of a large proportion of the staff. During one outbreak the epidemic type was also isolated from air, dust, bedclothes, and infants' gowns in the nursery. It was evident, therefore, that the epidemic types were widespread in the infants' environment, and the results of different surveys of staphylococcal types found showed that this high concentration of the epidemic type in the noses of the nursery staff was present not only at the height of an outbreak but also in the early stages of an epidemic.

It is accepted that the main reservoir of *Staph. pyogenes* is the upper respiratory tract of man, in particular the nasal passages; but the organisms may also be present on the skin of a considerable proportion of the population (Gillespie, Devenish, and Cowan, 1939; McFarlan, 1942), and higher carrier rates were found among hospital in-patients and nurses than among the general population (Miles, Williams, and Clayton-Cooper, 1944). In the present investigation 72 (70%) of 103 members of the staff swabbed on three different occasions were carrying *Staph. pyogenes* in the nose, and in 34 instances (33%) the strains isolated belonged to the epidemic type; 28 members of the staff who harboured *Staph. pyogenes* in the nose were also hand-carriers, and in 15 instances the strains cultured from the skin were identified as the epidemic type. No hand-carriers of *Staph. pyogenes* were found among the 31 members of the staff whose nasal swabs were also negative. There was therefore confirmation of the close association between nasal carriage and skin carriage of *Staph. pyogenes*. The high percentage of the staff found to be carrying the epidemic types was probably not an accidental congregation of persons harbouring those types, but more likely a gradual build-up of infection by a strain possessing the ability to implant itself and multiply in the nose when spread from person to person.

The possible sources of infection of the infant with *Staph. pyogenes* are those who come into contact with it, either directly or indirectly, and include mother, doctor, nurse, ward-maid, and laundress. The mother may infect her own infant during breast-feeding, but the evidence shows that the spread of infection takes place in the nursery. The contacts between doctor and infant after it has been born are in general irregular and transitory, and there is little or no evidence that he plays any part in the spread of infection. The same conclusion applies to the ward-maid, whose presence in the ward is of short duration with only indirect, if any, contact with the infants. The laundry is a potential source of infection, either through failure to rid blankets and infants' gowns and napkins of staphylococci or by infection during handling. The nurse is in regular and intimate contact with the infants, especially during toilet and hygiene, and the evidence suggests that she is the most important factor in the spread of infection. This evidence is based on the epidemiological, bacteriological, and serological findings, and as a result of visits to different maternity units and nursing homes in order to watch the procedure and technique of infant hygiene and nursing.

The possible paths of spread of infection are represented in Fig. 2, which shows infection spreading from the adult nose at the centre via hand, fomites, air, and dust to the infant's skin, nose, and eye at the periphery. In the present investigation *Staph. pyogenes* has been found to be so ubiquitous in the infants' environment that no precise conclusions could be drawn regarding the mode of spread. The serological types of *Staph. pyogenes* which were the cause of the outbreaks were isolated in cultures on repeated occasions from the sources shown in the centre and radii of the diagram, although infection of dust and air appeared to be low. The most probable path is via the nose and hands of the midwife or nurse to the infant's skin, but the infant's communal bath and towel also probably play an important part in the transmission of infection.

FIG. 2.—Potential paths of spread of infection in nurseries outbreaks of pemphigus neonatorum and conjunctivitis.

Knowledge of the possible paths of spread of infection alone will not suffice as a basis for the prevention or control of outbreaks of infection. Factors which facilitate the spread of infection must also be considered and steps taken to eliminate them. During visits to several maternity units and nursing homes in which outbreaks of pemphigus neonatorum had occurred, many such factors were noted. One of the chief among these was overcrowding and bad spacing of cradles or cots: in one large nursery capable of accommodating a maximum of 18, allowing a minimum of 25 sq. ft. (2.3 sq. metres) per cot, there were 18 infants. Insufficient ventilation and light, partly due to black-out conditions and the building of anti-blast walls were also noted as undesirable factors. In most of the units visited the wards and nurseries were cleaned by dry dusting, a practice which was immediately altered when attention was drawn to it. Associated with the overcrowding of nurseries the nursing staff was often inadequate, and too much of the toilet and hygiene of the infants had to be carried out by pupil midwives insufficiently supervised and still in an early stage of training with little or no knowledge of the nature of infection and modes of transmission. Other points facilitating the transmission of infection noted in different hospitals were: the communal changing-table covered with a towel on which infants were placed in turn; failure to disinfect the bath after use for each infant; failure to wash the hands before and after attending to an infant; toilet requisites handled by different nurses and used in common for all infants in the nursery. Masks were employed in all the maternity units and nursing homes visited, but in one large maternity unit masks were often worn covering the mouth only, leaving the nose exposed.

Until more precise knowledge is available of the path by which staphylococcal infections are spread in nurseries it is justifiable to recommend measures to prevent and control outbreaks covering a wider range than may later be found necessary. Benians (1943) showed that the mere closure of a ward in which an outbreak had occurred followed by cleansing and airing, was ineffective in terminating an outbreak, as fresh cases began to appear within three days of reopening the ward. It has also been pointed out by Elliott, Gillespie, and Holland (1941) that the use of masks, gowns, and rubber gloves alone did not have an observable effect on the spread of infection. Most of the

factors already noted as facilitating the occurrence and spread of infection suggest the obvious remedies—avoidance of overcrowding, adequate ventilation and natural light, a proper proportion of trained and untrained nursing staff with more supervision of the latter, and early training in the nature, sources, paths of transmission, and methods of prevention and control of hospital infections.

The ward or nursery should be cleaned by vacuum cleaner or by damp dusting. The infant's bath should be thoroughly disinfected either with undiluted lysol (M.R.C., 1941) or with 1% C.T.A.B. (Barnes, 1942) and washed after use by each infant, and well rinsed before again being used. So far as practicable a separate toilet outfit should be reserved for each infant, including the towel on which it is placed after its bath, if different from that with which it is dried. Consideration should be given to the changing of infants in their cots instead of on a communal changing-table, as is the practice in many maternity units, while the crib bath in an individual bath blanket has much to recommend it.

No member of the nursery staff—medical, nursing, or cleaning—should go on duty or enter the nursery if suffering from any acute upper respiratory infection or skin sepsis. Efficient masks covering both mouth and nose should be worn by all staff when in the nursery. Masks should be changed frequently, as they may become moist, rendering them inefficient and unpleasant to wear. The nurse's hands should be washed in soap and water and dried either with destructible tissue towels, which are again on the market, or on her own towel immediately before and after attending to an infant, and especially after every use of the handkerchief. Hamburger and Green (1946) have pointed out the importance of nose-blowing in the expulsion of *Staph. pyogenes* by nasal carriers, with infection of the hands and transfer from hands to secondary environmental reservoirs, such as clothing, bedding, towels, etc. This may be an important factor in the infant nursery as a source and mode of spread of staphylococcal infection, in view of the high percentage of persons in a semi-closed community, such as a hospital, who harbour *Staph. pyogenes* in the nose.

Members of the nursery staff who are aware that they are heavy nasal or skin carriers of *Staph. pyogenes* should be most meticulous in observing preventive measures even in the absence of staphylococcal infection in the nursery. Attempts to clear profuse nasal carriers of *Staph. pyogenes* with sulphathiazole snuff or ointment have not had the hoped-for success, but the application of penicillin ointment to the nostrils two or three times daily and sniffed in, recommended by Hobbs, Carruthers, and Gough (1947) as an adjunct to the treatment of sycosis barbae, may be more effective.

The numerous administrative and technical procedures necessary to prevent and control the spread of infection among infants in large nurseries in maternity hospitals—procedures which in many instances are not possible or practicable—give rise to consideration of the question whether the large infant nursery should not eventually be discarded in favour of the mother and infant being nursed together in a cubicle or in small wards. Apart from the respiratory and intestinal infections to which the newborn infant is so highly susceptible, it would not be exposed to the high concentration of infection which develops in a nursery in the earliest stages of an outbreak of pemphigus neonatorum, and the number of contacts, direct and indirect, would be very considerably reduced. The primipara, moreover, would have more opportunity for guidance and practice in the feeding, toilet, and hygiene of her infant. In any event the prevention and control of infection should be based on high standards of nursing technique and infant

hygiene as exemplified in Medical Research Council War Memorandum No. 11 (1944).

### Summary

An outbreak of pemphigus neonatorum and staphylococcal conjunctivitis affecting 132 infants in a large maternity unit over a period of two years is described.

Serological identification of strains of *Staph. pyogenes* isolated from the lesions of all the cases showed that there were three outbreaks, each due to a distinct serological type of the organism; there were also a small number of sporadic cases due to different serological types of *Staph. pyogenes*.

Investigations in one large nursery in which 93 of the cases occurred showed that the infecting strain was widespread in the infants' environment, and was isolated from the noses of a high proportion of the nursing staff, from the noses of healthy infants, from blankets and gowns, and from dust and air in the nursery.

The findings indicate that the infants were infected in the nursery and not from their mothers.

The evidence suggests that the main reservoir of infection was the nasal passages of the nursing staff, whence infection was spread to the infants, probably via the hands.

Recommendations are made for the prevention and control of staphylococcal infection in infant nurseries.

We gratefully acknowledge the facilities afforded to us for these investigations by Dr. John Jones, City Lodge Hospital, Cardiff, and the willing and valuable co-operation of Dr. Olwen Williams, Sisters Friday and Davies, and the staff of the maternity unit. We also obtained much valuable help and information from several other maternity units and private nursing homes.

There are now 12,000 industrial canteens known to the Chief Inspector of Factories, and more than half of these are in factories employing fewer than 250 workers. The Industrial Welfare Society has produced an illustrated brochure (4s. 6d. post free) entitled *Canteens in Industry*, which takes the form of a guide to the planning and management of these enterprises. It was first published at the beginning of the war and has now reached its sixth edition, incorporating a large amount of wartime experience. Suggestions are made concerning site, accommodation, lay-out, internal construction, lighting, heating, ventilation, furnishing, and colour scheme. There is a chapter on food and diet in which a number of useful hints are given, as, for example, the great food value of oily fish, such as the herring and mackerel; the need for making soups a substantial dish, of nourishing quality and distinctive flavour; the help of the friendly and filling dumpling; other accessories in making the available meat go; popularization of vegetables, especially the lesser value of salads, particularly if they include ingredient such as a good portion of potato or as an alternative to sweets; and also the value of supplementing minerals and vitamins.

# GALL-BLADDER COMPLICATIONS FOLLOWING RESECTION OF STOMACH FOR PEPTIC ULCER\*

BY

C. L. H. MAJOOR, M.D.

*Department of Medicine and Röntgen Diagnosis*

AND

Th. J. J. SUREN, M.D.

*Department of Surgery**(From the "Charitas" Hospital, Roosendaal, N.Br.,  
The Netherlands)*

Abnormal conditions in the upper abdomen which may occur after resection of the stomach for peptic ulcer may be considered under several heads. A detailed investigation into the occurrence and frequency of gastro-jejunal ulcers would be outside the scope of this paper. Occasionally, during the past five years, we have observed severe haemorrhage following gastric resection, but on no occasion was there demonstrable radiological evidence of ulcer. It was noted that the patients rarely complained of pain. Symptoms arising from internal strangulation of the small intestine by abnormal hernial rings are less frequent (for literature, see Suren, 1941).

Of common occurrence are less serious complaints, often of a temporary nature, as observed by Wangenstein (1944). He did not encounter serious disorders or anastomotic ulcers. Poor appetite and a feeling of satiety are common, especially after partaking of liquid food. It would be incorrect to ascribe these phenomena to over-filling of a stomach of reduced capacity; for most radiologists are acquainted with the rapid emptying which follows resection. A reasonable presumption would be that the liquid either fills the afferent loop of the anastomosis or interferes with the flow of pancreatic biliary juices from that loop. Symptoms may conceivably arise in this manner, and they can be anticipated and prevented by advising the patients to eat dry food. It is an outstanding fact that porridge and milk no longer agree with patients who, prior to operation, had lived almost entirely on that diet. Frequently there is an aversion to fatty foods. Finally, some patients are troubled in the early post-operative period by regurgitation of bilious fluid. It is inferred from these findings that the downward flow of bile is impeded in resections of the Billroth-II type. In many instances the resulting complications are slight and of a temporary nature. They may, however, be serious.

Stolte (1942) carefully observed 333 cases of ulcer in the Department of Medicine of the "Onze Lieve Vrouwe" Hospital at Amsterdam. Of these 333 patients 83 had previously undergone gastric resection and 26 had had gastro-enterostomy. Stolte found that gastro-jejunal ulcer was a complication in eight of those resected and in ten of those with gastro-enterostomy. Further, 22 patients after resection and four after gastro-enterostomy continued to have symptoms; but in no case could gastro-jejunal ulcer be demonstrated with certainty. The number of patients with abdominal symptoms after operation on the stomach is remarkably large in this series. Their complaints were serious enough to warrant their admission to the medical clinic after they had been operated upon.

We are greatly impressed with the fact that in Stolte's series severe unaccountable symptoms following stomach

operations were more frequent than those arising from proved anastomotic ulcers, and that they were proportionately more frequent after resection than after gastro-enterostomy. Stolte does not state whether he examined the gall-bladder in investigating his series. One sees a similar picture in a review by Kingma (1939) of 65 cases of primary resection operated upon according to the Billroth II method for perforated ulcer. Severe symptoms persisted in six cases; but in only one was gastro-jejunal ulcer (repeated haemorrhage) the probable diagnosis. In the remaining five the diagnosis was uncertain; four of the patients complained of pain and three found that fat did not agree with them. No special attention was paid to the gall-bladder in this investigation.

During the past few years we have learned that severe symptoms occurring after gastric resection by the Polya-Balfour-Reichel type of operation are frequently caused by gallstones. We have not found this fact stated in the literature which we have studied, nor do Wangenstein, Stolte, or Kingma mention it as a possibility. The following case is noteworthy.

## An Illustrative Case

Mrs. B. (Case 1), aged 36, was admitted to hospital on April 20, 1943. She had suffered from symptoms referable to the stomach since she was 16. The symptoms had an obvious periodic incidence, and during two pregnancies they were entirely absent. Pain was mostly referred to the left side of the abdomen, was unrelated to the taking of food, and was manifest in attacks lasting for ten or fifteen minutes. The patient did not complain of heartburn, nor did she vomit. In 1938 the pain disappeared when she was given ambulatory treatment elsewhere. In 1942 there was a slight recurrence. Since the autumn of 1942 the patient was never really free from pain.

Nothing of note was discovered on general examination. Some not very dark bile was found on duodenal intubation and no cholesterol crystals were seen in the bile sediment. Test-meal findings showed: free HCl 15°; total acidity 20°. There were no abnormal findings in blood or urine. Radiological examination of stomach and duodenum revealed "kissing ulcers" of the duodenal bulb. After the oral administration of tetraiodo-phenolphthalein in fractions, two of 3 g., a fair-sized gall-bladder was observed, duly filled with dye and free from stones.

On May 5 partial gastrectomy of the Polya-Balfour-Reichel type was performed. The post-operative course was complicated by severe pulmonary embolism on the nineteenth post-operative day. This complication was confirmed by observing a pleural friction rub over the foremost part of the right lower lobe. On June 20 she was discharged from hospital.

On April 12, 1945, the patient reported sick again. After the operation she had remained symptom-free for six months, except for nausea after food. In November, 1943, she had a violent cramp-like pain in the epigastric region after drinking home-made liqueur. From October, 1944, the attacks of cramp became more frequent. The patient did not become jaundiced, nor did she notice any darkening of the urine. She vouchsafed the information that these attacks of pain were of more sudden onset and of greater severity than the pain experienced before the stomach operation. "It is not my stomach," were her words. The pain was localized to the left subcostal region and did not radiate. Physical examination was negative; the blood and urine were normal. The previous operation rendered duodenal intubation impracticable. Radiography of the gall-bladder, using "biliselectan," revealed that it did not fill. A diagnosis of gallstones was made.

Cholecystectomy was performed on April 13. The gall-bladder contained thick bile and more than a thousand small stones of varying sizes. The post-operative course was complicated by slight infiltration of the right lower lobe, which responded to sulphathiazole. On May 2 the patient was discharged from hospital, and when she reported for medical inspection on Jan. 21, 1946, was in excellent condition and

\*This paper is dedicated to our friends and colleagues of the Expeditionary Force serving in the neighbourhood of Roosendaal in the winter of 1944-5.

free from pain. Milk and milk puddings do not agree with her, but she tolerates all other foods, even fatty ones.

We are reasonably certain that the gall-bladder was normal at the time of the partial gastrectomy. The first symptoms, presumably due to the gall-bladder, appeared six months after the operation, and one naturally surmises that there was some relationship between the resection and the development of cholelithiasis.

experienced before the operation. The history of Case 2 is less definite: the colicky pains which she had before her gall-bladder operation had certainly never occurred before the resection. All patients now complained of attacks of pain of short duration, recurring at intervals, sometimes long and irregular. The pain was often localized to the upper abdomen and on the left side. Slight transient jaundice occurred once only (Case 5).

|| Cases of column 5 are included in columns 1 and 2.

### Observations on Six Cases

Further observations are given in Table I. In none of these cases have we any exact knowledge of the state of the gall-bladder before stomach resection. There are, however, certain pointers to the improbability that any gallstones were present at the time of operation. Symptoms arose in all cases after periods of 6 to 37 months of freedom from pain. Patients Nos. 1, 3, 4, 5, and 6 said most decidedly that the nature of the pain was quite different from that

We can put forward important arguments (unpublished data) favouring the hypothesis that all gallstones, in our part of the country at any rate (i.e., North Brabant area of South Holland), originate as minute cholesterol particles, which aggregate to mulberry-shaped stones. All the stones found in our six patients belonged to these very young formations. This fact is in accordance with our supposition that these stones have originated only after the resection. That relief from pain followed cholecystectomy is very

strong evidence that the gallstones were the cause of symptoms in the five patients who were operated upon.

The diagnosis of cholelithiasis was entertained only after much hesitation in respect of our earliest patients. From Table I it appears that the gall-bladder was not visible in the skiagrams of three out of five photographed patients. Jaundice was always lacking at first. Further, after partial gastrectomy duodenal intubation (the findings of which manœuvre we consider valuable) is no longer applicable as an aid to diagnosis. At first we thought that the altered gastric properties, after gastrectomy, might interfere with the resorption of the contrast medium from the intestine. Later it became clear to us that oral cholecystography, even after gastrectomy, is a reliable procedure, and that a gall-bladder which is not filled—certainly after the examination is repeated—is strong evidence of the presence of gallstones. Sassen and Wijnen (personal communication) came to a similar conclusion when they examined radiologically the gall-bladders of a number of patients who had been operated upon by the Billroth II method. Normal filling of the gall-bladder was found in the great majority. These examinations were conducted for the purposes of information on patients without symptoms.

In order to estimate the incidence of gallstone formation following gastric resection we compare, in Table II, those cases observed after gastric resection with all gastrectomies for ulcer and all cholecystectomies performed for stones or inflammation in corresponding years. The first impression, no doubt, is that gallstones are so often encountered during operations for ulcer that their occurrence after a resection is a mere coincidence. The simultaneous occurrence of ulcer and gallstones was observed seven times (Table II, columns 3 and 4), although this association was not systematically sought for in 1943 and 1944. Gallstones following resection were observed only on six occasions. It is emphasized that the stones found together with ulcer were on four occasions of an old or very old type, and small cholesterol stones were present on three occasions. In this respect already the two series in Table II differ. The proportion of males to females also differs. The comparison is made in Table III.

TABLE III.—Incidence of Gallstones After Gastric Resection :  
the Sexes Compared

	Cases	Female	Male	Ratio
				F. : M.
Cholecystectomies on account of stones or inflammation	219	187	32	5.8 : 1
Resections on account of ulcer	174	30	144	1 : 4.8
Gallstones ascertained some months after resection for peptic ulcer	6	2	4	1 : 2
Gallstones found during resection for peptic ulcer	7	6	1	6 : 1

As in normal experience, there was a female preponderance in gall-bladder operations, and men had the larger share in stomach resections. In the group where stones were found at operation for ulcer the male/female ratio corresponds to that for the cholecystectomy group. In the group of gallstones following resection the male element predominates, approaching the male/female ratio for resections. Although our series is a small one and by no means conclusive there is presumptive evidence that in the condition of gallstones following resection for gastric ulcer the resection itself may play a part. The evidence becomes all the more certain when we bear in mind that of 32 males operated upon for gallstones in 3½ years three had already had resection of the stomach. (Our fourth male patient has not yet been operated upon and has not been included in this computation.) One out of ten males undergoing cholecystectomy had therefore had a previous stomach

operation. This high occurrence rate also suggests that the gastric resection may predispose to cholelithiasis. Nor can it be maintained that one male in ten in this part of Holland undergoes gastric resection.

### Discussion

There are five arguments in support of our view that resection of the stomach by the Billroth II technique may cause gallstones to develop: (1) the striking observation in the case of Mr. B.; (2) the evident discrepancy in the symptoms of our six patients (who developed gallstone complaints after resection) before and after the stomach operation; (3) the discovery of young stones exclusively; (4) the distribution of our cases between the sexes; (5) the fact that the gallstone symptoms always appeared shortly after the resection (6–37 months) may point in the same direction.

Even if this thesis is acceptable there are some problems still outstanding. It is not clear in what way the resection predisposes to gallstone formation. It is easy to visualize altered duodenal flow and pressure being reflected in the biliary system. Such alterations may explain the vague nature of the symptoms after many resections. It is possible that the precipitation of cholesterol is facilitated under the new conditions. If this hypothesis should be substantiated it would be interesting to know if there is any incidence of gallstones after the Billroth I type of operation.

It is especially important to know if the manner of attachment of the jejunal loop has any bearing on the formation of gallstones. Among the six cases under discussion the efferent loop was attached to the greater curvature on at least five occasions. This procedure has the advantage of virtually preventing pinching-off of the small intestine (Suren, 1941; Kummer, 1941). If, however, the manœuvre should involve the bile ducts in abnormal conditions it is doubtful if it would be wise to continue to use it.

It is difficult to understand why cases with gallstones following resection have not before been published. There was no mention of such a condition in the literature at our disposal. The diagnosis is undoubtedly difficult unless its possibility is always considered. The symptoms in all our cases were of colic; but the localization was uncommon for biliary colic and only once was there any jaundice. All the patients were referred with the provisional diagnosis "stomach cramps." A striking instance in point was Case 6. Four weeks after gastrectomy (Oct. 15, 1943) this patient acquired a small post-incisional hernia which was symptomless. On Feb. 11, 1946, he had a violent attack of pain in the epigastrium. Strangulation of the hernia was suspected and he was sent to hospital. At the operation the gall-bladder was purposely inspected, and on finding that it was full of mulberry gallstones it was removed. We believe that more cases of gallstones following resection will be discovered if they are systematically investigated.

The history of another of our patients (P.v.E.) is illuminating in that gallstones were not found, although the symptoms he presented suggested that probably they were present. He was born on March 12, 1917, and had had medical treatment for duodenal ulcer in 1939 and 1940 and gastrectomy on March 19, 1941, when he was found to have "kissing" ulcers of the duodenal bulb. The operation was after Polya-Balfour-Reichel, the gastro-jejunal anastomosis being effected with efferent loop at the lesser curvature. On June 15, 1943, he reported as an out-patient with symptoms of epigastric pain which had been present for one and a half years. Skiagrams showed a normal resection stomach without ulcer and a gall-bladder with moderate filling and without stones. A trial break-fast showed free acid 14°, total acidity 20°. On March 13, 1945, the investigations were repeated because of violent attacks of pain after taking milk, cabbage, peas, and beans. A fractional

test meal revealed no free acid. There were no obvious abnormalities of the stomach and gall-bladder on x-ray examination. Dietetic treatment was given. On Feb. 23, 1946, he reported again at the out-patient department. He had been free from symptoms for seven months, but during the preceding few weeks he had renewed attacks of pain, mostly after milk and porridge. Once more there was no abnormality of the gall-bladder. He was completely free of symptoms after some days of complete rest and frequent small meals with little fat and without milk.

### Conclusions

From a total of 220 extirpations of the gall-bladder and 174 resections of the stomach over a period of 3½ years it was observed that gallstones occurred on six occasions shortly after a resection. As a result we believe that it is necessary, when patients complain of pain after resection, to look for the cause in the gall-bladder rather than the anastomosis. Some arguments support the view that the Billroth II type of operation may further the formation of gallstones.

## DIATHERMY DISSECTION OF THE GALL-BLADDER

BY

R. J. McNEILL LOVE, M.S., F.R.C.S.

Surgeon, Royal Northern Hospital, London

Eight years ago I published, jointly, an illustrated article on Thorek's method of electrosurgical obliteration of the gall-bladder without drainage (Bailey and Love, 1939). Briefly, this entailed partial removal of the gall-bladder and coagulation by diathermy of the strip which was left *in situ* attached to the liver. The main advantage of this operation, as compared with the standard cholecystectomy, was that drainage was unnecessary. We reported a series of 129 consecutive and unselected cases with no mortality, and in only seven were there post-operative complications. These included four patients who developed infection of the abdominal wall, one whose wound broke down on the fourth day, and two cases of biliary fistula following drainage of the common bile duct. These fistulae eventually closed spontaneously. We mentioned that in some cases the gall-bladder possessed a more or less complete mesentery, so that it was possible to remove the entire organ without damage to the liver capsule. The gall-bladder bed was then coagulated with a diathermy button and the peritoneal edges were sutured over the exposed area. If the area was too wide to cover with peritoneum a detached piece of falciform ligament or an omental graft was sometimes tacked over the surface.

The very satisfactory results which followed the diathermy dissection of the gall-bladder in cases in which the organ was loosely attached to the liver prompted one to apply it as a routine in all cases suitable for a complete cholecystectomy. Exceptions are patients in whom a cholecystostomy is the more prudent measure, or occasionally the gall-bladder is so embedded in the liver that it is easier and safer to perform Thorek's operation.

Diathermy dissection of the gall-bladder is, as a rule, an easy operation, and differs from the standard cholecystectomy only in that, after identification and ligation

of the cystic duct and artery, a diathermy knife is used to divide the peritoneum on either side of the gall-bladder (Fig. 1). The viscus is then dissected from its bed with the diathermy knife, care being taken that the knife is applied to the gall-bladder rather than to the bed. Thus, Glisson's capsule is unlikely to be damaged, and subsequent seepage of bile and blood is reduced to a minimum. If necessary any raw areas from which bile or blood exudes are coagulated with a diathermy button (Fig. 2). During dissection of the gall-bladder from its bed a constant watch must be kept for the presence of a cholecysto-hepatic duct (Fig. 3). This is an uncommon anomaly—for example, Flint (1923), in his review of 200 cases of the anatomy of the bile ducts and vessels (in which only 69 followed the textbook description), did not record a case. Neuhof and Bloomfield (1945) describe two cases in which the duct measured about 2 mm. in diameter. In one case it was unrecognized, and a fistula resulted which closed in forty-five days, and in the other the duct was recognized at operation and closed with a purse-string suture. When the surgeon is satisfied that the gall-bladder bed is dry the area is covered by approximation of the peritoneal flaps, reinforced, if necessary, with a graft of omentum or falciform ligament. The wound is then closed without drainage.

Excluding cases in which drainage of the common bile duct, or very occasionally the gall-bladder bed, was considered necessary, I have during the past 10 years operated on 332 cases of gallstones. The procedures adopted were: cholecystostomy, 18; Thorek's operation, 81; diathermy dissection, 233.

*Cholecystostomy* was advisable in some cases of empyema of the gall-bladder, or when the viscus was buried in adhesions so that anatomical dissection was impracticable, especially if the patient was obese. In these cases safe surgery resolved itself into removal of calculi and drainage of the gall-bladder.

*Thorek's operation* was performed when the biliary tract could be exposed, so that the cystic duct and artery could be ligated with safety. When a fibrotic and contracted gall-bladder is partially buried in the liver removal of part of the viscus, with coagulation of the embedded portion, entails less risk than a complete cholecystectomy. It should be mentioned, however, that many of the early

FIG. 1.—Division of the peritoneum with a diathermy knife in dissection of the gall-bladder.

FIG. 2.—Coagulation of raw area with a diathermy button.

FIG. 3

cases in which Thorek's procedure was adopted would now, with increased experience, be dealt with by diathermy dissection.

*Diathermy dissection* was performed in 233 cases and two deaths occurred. The first fatality involved a somewhat feeble elderly male, who faded away a few days after the operation in what was apparently a combination of cholaemia, uraemia, and myocardial failure. The second fatality was due to failure to recognize the presence of a cholecysto-hepatic duct, and the history was as follows:

A woman aged 43 had a pre-operative diagnosis of gall-stones confirmed by a cholecystogram. The patient was somewhat obese, and the operation was rendered more difficult than usual, as adhesions between the diaphragm and upper surface of the liver prevented more than a moderate degree of rotation of that organ. However, there was not much difficulty in clearly exposing the junction of the cystic and common hepatic ducts, and the cystic duct and cystic artery were ligated in the usual manner. During diathermy dissection of the gall-bladder from its bed some discharge of bile was noticed, but this ceased when the raw area was coagulated with a diathermy button. Owing to the limited rotation inspection of the gall-bladder bed was somewhat restricted, but as it appeared to be dry the peritoneum was sutured over it and the wound was closed.

On the following day the patient complained of epigastric distress, and a tense swelling was obvious in this region. Some of the sutures were removed and sinus forceps introduced. About 15 oz. (425 ml.) of bile escaped, and a rubber drainage-tube was introduced. A biliary fistula developed, but there was no evidence of obstruction of the biliary ducts, and the faeces were well coloured. It was hoped that the fistula would close spontaneously, but after three months hope began to fade. It was proposed to temporize for another three months, and then, if necessary, dissect out the fistula and implant it into the jejunum. However, the patient developed menopausal melancholia, which was doubtless aggravated by her unfortunate condition. She became uncontrollable, constantly removing her dressings and making determined efforts to return to her home. Surgical intervention was obviously imperative, so the wound was reopened and the track of the fistula dissected from the abdominal wall and traced towards the under surface of the liver. The fistula was implanted in a loop of the upper jejunum. Three days later the wound broke down and the biliary discharge reappeared. The mental condition of the patient deteriorated and she died about one month later.

I was not at that time aware of the existence of the cholecysto-hepatic duct, and attributed the fistula to "slipping" of the ligature which was applied to the cystic duct. This was not very convincing, as the duct was easily identified and secured with No. 60 thread, which has a better frictional grip than catgut. On reviewing the case I now believe that the fistula was caused by division of an unrecognized cholecysto-hepatic duct.

#### Advantages of Diathermy Dissection

The average mortality of standard cholecystectomy in skilled hands is about 2%. Lung complications, including pulmonary embolus, account for the majority of fatalities. Both these conditions are predisposed to by restricted respiratory excursions. In the standard cholecystectomy a puddle of bile and blood collects beneath the diaphragm and the necessary drainage-tube causes further subphrenic irritation. Diaphragmatic spasm results, and inefficient aeration of the lungs predisposes to basal atelectasis. Also, as the piston-like action of the diaphragm is an important factor in maintaining an efficient venous circulation, impaired movements encourage venous stagnation, and associated risk of thrombosis and possible embolus accrues.

If Thorek's (1938) operation or diathermy dissection is employed, subphrenic irritation is reduced to a minimum. The risk of the above-mentioned complications is proportionately reduced, and the mortality is in the region

of 0.5%. In addition, convalescence proceeds more smoothly, tedious but non-lethal chest complications are uncommon, and thrombosis of the iliac or femoral veins is almost unknown. Also, the necessity for frequent removal of bile-soaked dressings is obviated, with the advantage that the patient is spared routine disturbances, and the time of the nursing staff is not occupied with the continual preparation of dressing trolleys. Finally, it is exceptional for the wound to heal other than by first intention.

#### Exploration of the Common Bile Duct

This procedure considerably increases the risk of the operation, and some authorities quote a mortality figure of 10% when drainage of the common duct is performed. The increased mortality is partly due to the fact that in many cases drainage is required when obstruction is present, as a result of which cholangitis and cholaemia are often associated complications. In addition, the insertion of a T-shaped tube into the common bile duct is time-consuming and necessitates intricate manœuvres under deep anaesthesia. However, palpation of the duct may reveal an obvious calculus which demands removal, and in other cases it is usually wise to explore the common duct if there have been attacks of colic or recurrent jaundice, or if obvious dilatation of the duct is discovered at operation. If exploration is necessary the cystic duct is usually slit up and the incision carried into the common duct as far as required. Through the aperture the duct can be explored with a malleable probe, which, in the absence of obstruction, should readily pass into the duodenum. Desjardin's forceps are useful for withdrawing calculi or debris from the duct.

At the operation doubt not infrequently arises as to whether the common bile duct should be explored or not. The surgeon is naturally averse to adding unnecessarily to the length and difficulty of the operation, but, on the other hand, it is even less desirable to overlook such a condition as a calculus impacted in the duct.

#### Choledochography

This is a simple procedure which provides valuable information concerning the condition of the common bile duct. Information regarding the calibre of the duct, the discovery of a filling defect due to a calculus, and the presence of obstruction from other causes such as pancreatic compression are of value to the surgeon who is pondering on the necessity for exploring the common duct.

*Technique.*—It is preferable that the choledochogram is taken before cholecystectomy is performed, as an intact cystic duct is more readily manipulated than a blind stump. Traction on the gall-bladder renders the cystic duct taut, and the wall is nicked with sharp-pointed scissors at a point about half an inch (1.25 cm.) from its fusion with the hepatic duct. A malleable cannula is the most suitable instrument for the introduction of the opaque medium, but an ordinary cannula or a short length of suitable rubber tubing may be used. The cannula, attached to a suitable syringe, is introduced through the cystic duct, and about 5 ml. of lipiodol is injected during a period of five seconds. As the last of the fluid is introduced the exposure is made and should be as short as possible. The film is ready for inspection within five minutes. It is important to remove metal retractors and unnecessary instruments from the field of operation immediately before the film is taken; otherwise opaque shadows may obscure the duct. During the interval of waiting the surgeon can perform appendicectomy if advisable, or else proceed with the gall-bladder dissection. In order to facilitate manipulation of the ducts the gall-bladder should be retained until a decision has

been reached as to the necessity for exploring the common duct. If exploration is deemed necessary the slit in the cystic duct is extended to permit the introduction of suitable instruments. In cases of infection or back pressure, drainage of the duct can be obtained, if necessary, by a T-shaped tube introduced through the opening. If exploration of the common duct is not required, then the cystic duct is divided and the distal end is ligated with silk or thread. Cholecystectomy is then performed.

By revealing a filling defect a choledochogram may prevent the surgeon from overlooking some condition which demands exploration of the duct. Thus a calculus may be more or less embedded in the wall of the duct and cause no appreciable obstruction to the passage of an instrument.

FIG. 4.—Choledochogram showing distended duct and patent lumen.

On the other hand, the choledochogram may indicate that although the duct is distended the lumen is patent, and consequently exploration is not necessary.

Fig. 4 illustrates such a case: the duct was about three times the normal size, but lipiodol flowed freely into the duodenum. An unnecessary exploration was therefore avoided. The condition was due to subacute pancreatitis and consequent compression of the duct. Simple diathermy cholecystectomy was per-

formed; the patient made a good recovery and has remained in good health.

### Post-cholecystectomy Syndromes

After removal of the gall-bladder, and possibly a handful of stones, the patient naturally hopes to be rid of symptoms. But disappointments following cholecystectomy are not uncommon, though most of them are preventable or curable. Briefly, some of the more important causes of post-cholecystectomy syndrome are as follows:

1. A calculus, or calculi, may remain undetected in the hepatic or common duct and give rise to further attacks of hepatic colic or obstruction. The hepatic duct should be explored if a stone is removed from the common duct, as retrograde migration of small calculi occasionally occurs. In some conditions, such as acholuric jaundice, small cinder-like stones are found in all the ducts, and irrigation of the hepatic duct is advisable in order to dislodge calculi which might not otherwise be detected. A choledochogram is a valuable precaution against overlooking a calculus in the common duct.

2. Chronic parenchymatous pancreatitis is often associated with infection of the biliary tract. Symptoms, including epigastric discomfort and flatulent dyspepsia, persist owing to deficiency of the external secretion, but they are relieved by the administration of a pancreatic preparation, such as "liquor pancreaticus," "panteric," or "pancrobilin." I referred to this syndrome many years ago (Love, 1933).

3. Spasm of the muscle of Oddi is alleged to be the cause of biliary colic which occasionally occurs after chole-

cystectomy. Cases apparently of this nature have been described by Maurice Lee (1946). Antispasmodics certainly relieve the symptoms, and pethidine, 25-50 mg., should be prescribed thrice daily, combined with an early morning saline aperient.

4. Dilatation of the stump of the cystic duct is apt to occur after cholecystectomy unless the duct is ligated within a quarter of an inch (0.6 cm.) of the common duct. Petersen (1946) records 42 cases, and states that the "re-formed gall-bladder" may be as large as a normal organ. I have on two occasions removed a single calculus from the stump of the cystic duct. In both cases intermittent jaundice was the predominant symptom, presumably due to exacerbations of infection around the stone and consequent pressure on the converging hepatic duct. A dilated cystic duct is usually buried in adhesions, and may be recognized only after probing through an incision in the common duct.

5. Conditions unrelated to the biliary apparatus may account for symptoms which persist after cholecystectomy. The appendix should always be removed during the operation of cholecystectomy, unless local conditions or the general condition of the patient preclude further operative intervention. The retention of a pathological appendix sometimes accounts for post-cholecystectomy symptoms. Presumably, when the gall-bladder is removed adjacent organs are scrutinized, in which case a peptic ulcer is recognized and receives appropriate treatment. Occasionally adhesions develop between the pylorus or duodenum and the gall-bladder bed. These are apt to cause angulation or even obstruction, but are unlikely to occur if the gall-bladder is removed by diathermy dissection.

### Summary

When cholecystectomy is performed diathermy dissection of the gall-bladder is the method of choice. In the large majority of cases this is a simple and safe procedure, and the dry abdomen can be closed without drainage, with the great advantage that subphrenic irritation and consequent spasm of the diaphragm are reduced to a minimum. As compared with the standard operation chest complications and pulmonary embolism are much less common—a fact which is reflected in the lower mortality and reduced morbidity.

The technique and value of choledochography are discussed, and a summary is presented of some of the causes of post-operative persistence or recurrence of symptoms.

A report of the Joint Tuberculosis Council (copies may be obtained from the Hon. Sec., 1, Becket Street, Oxford) sets out its views on the organization of the tuberculosis service under the National Health Service Act. The Council advocates that the Minister of Health should appoint a Central Advisory Committee for Tuberculosis and that there should be at least one member on the Central Health Services Council with a special interest in tuberculosis. It suggests that the Minister should create a direct link between the Regional Hospital Authority and the Tuberculosis Dispensaries, and that the tuberculosis service should be co-ordinated on a Regional level, each Regional Board appointing a tuberculosis committee for that purpose. The board should also appoint a Regional tuberculosis physician. The Council emphasizes that the health visitors provided by local authorities should hold either the Certificate of the Tuberculosis Association or the Health Visitors' Certificate, or preferably both. Local health authorities should establish tuberculosis subcommittees empowered to delegate to local voluntary care committees some functions relating to prevention, care, and after-care. The Council regards such voluntary agencies as important in tuberculosis work.

# THE LONGEST SPAN OF LIFE BASED ON THE RECORDS OF CENTENARIANS IN ENGLAND AND WALES

BY

V. KORENCHEVSKY, M.D.

*From the Gerontological Research Unit, Oxford*

In stating their aims and planning schemes of research contemporary gerontologists stress the primary importance of making old age stronger, "to add life to years, not just years to life." At present old age is considered to be a pathological condition because senile decay appears prematurely and is aggravated by disorders that are not necessarily associated with normal old age, such as arteriosclerosis, hypertension, "senile" heart, some degenerative changes of liver and kidneys, mental deterioration, certain metabolic disturbances and auto-intoxication, gastrointestinal auto-intoxication, hypertrophy of prostate, etc.

This problem of gerontology, however, cannot, for two reasons, be dissociated from the other gerontological problem—that of how to increase the span of human life. (1) Most old people cling very strongly to life. Old men have the same right to a normal and healthy existence as children or adults, even though their most useful period of life has ended. (2) Besides this factor there is a scientific reason. The development of science and medicine must proceed in spite of and with complete disregard to all possible complications of a social and political kind. For many scientists and medical research workers the problem of ageing is fascinating not only because it affects the well-being of every man and woman, but also, and often chiefly, because it is one of the greatest and most fundamental mysteries and riddles in biology and medicine, because present old age is considered abnormal, and because if this is so this abnormal process of life has to be made normal. Science and medicine will not rest until they solve the riddle of what is normal ageing and normal old age and what is the normal span of life.

From the point of view of longevity, the centenarians of the past and the present are of especial interest because the length of their life indicates the limit which is theoretically and potentially possible for every human being. With reservations, investigation into their ancestry and progeny might be useful in solving the genetical causes of longevity, while an examination of their mode of living, and of the functioning of their organism, with a post-mortem investigation, might contribute to some other problems of gerontology and geriatrics.

## Difficulties of Investigation

There are several difficulties in the scientific investigation of centenarians, particularly as to their exact age. The basic information should be obtained from certificates of birth and death, of which the former presents the greatest difficulty, since it is often absent or doubtful. Young (1899) has fully discussed this and some other difficulties.

In the present paper data on centenarians are given only from 1930 to 1945, it being presumed that in this period the information and documents were more accurate than in the previous years, since the people of this country have gradually been trained in this respect. These data have been obtained from the most reliable sources available—for

I should like to express my gratitude to Lord Nuffield for the grant which has made possible the establishment and work of the Gerontological Research Unit, and to Oxford University, Prof. A. C. Hardy, and Prof. E. G. T. Liddell for the kind hospitality extended to the Unit in the Departments of Zoology and Physiology.

the years 1930 to 1937 from the Registrar-General's *Statistical Reviews* for England and Wales, and for the years 1938 to 1945, as a personal communication, from the Registrar-General's Office at Somerset House, London. The dates of birth, however, were not verified by birth certificates, but were obtained from the persons who registered the deaths, which fact decreases the value of the data. These data have been divided into two periods, each of 8 years—namely, 1930–37 and 1938–45—and are summarized in Tables I and II. Examination of the figures in these tables reveals at once a constant and obvious fact—that the number of women centenarians is considerably larger than that of men, being about 4.4 times greater in the first period and about 4.9 times greater in the second period (Table I). Further, in the second period the actual

Sex	Period	Age (years)												
		100	101	102	103	104	105	106	107	108	109	110	111	112
Men	I	59	31	21	14	9	2	1	—	—	—	—	—	—
	II	63	36	25	6	3	5	3	3	2	1	—	—	1
Women	I	264	155	81	46	22	20	5	3	4	1	—	—	—
	II	320	191	100	53	34	14	7	1	5	—	—	—	—

number of women centenarians is significantly greater ( $P < 0.02$ , Fisher's test for small samples) than that in the first period. The increase of male centenarians in the second period was only slight, and was statistically not significant.

## Limits of Longevity

From Table II it is clear that longevity of human beings might extend up to 109 and even 112 years. The age of 106–112 years has been reached by 11 (3.9%) out of 285 male centenarians and by 26 (about 2%) out of 1,326 female centenarians—that is, from both sexes a slightly larger relative proportion of men reached the oldest age. In favour of these data being of considerable value and comparative reliability is the fact that in each period investigated the annual figures of centenarians (Table I) are more or less constant, both for men and for women.

When calculated per year and per unit of the population (Table I), for 20 millions of men or women there were 17.7 male centenarians and 71.4 female centenarians in period I, and 18.3 and 83.4 respectively in period II. This fact indicates that the increase in the number of centenarians in period II cannot be explained by an increased population only, but appears also to be connected with increased longevity.

Ernest (1938), reviewing all the cases of centenarians which have been critically investigated by different authors and by himself, concludes that the longest reported span of human life was trustworthy in four cases only. "Two

of these four people lived over 110, one was nearly 112, and one over 113 years at death" (p. 55), residing in the U.S.A., Guernsey, Ireland, and Canada respectively. All the other cases of greater longevity reported in the literature, scientific and non-scientific, cannot be accepted as trustworthy. The distinguished Swedish gerontologist G. Backman (1945) also concludes that 113 years could be taken as the accurate age of the longest span of human life recorded, but that 125 years might perhaps be expected. Prof. I. Fisher (1923, p. 112), of Yale University, reports a comparatively recent case of life up to 120 years in Oregon, U.S.A., the case having been investigated by the Oregon Historical Society.

### Prolongation of Life in the Future

As to the possible prolongation of human life in future beyond the extreme age already reached by some centenarians (113 years), the scientists who studied this problem give different prophecies. Prof. Warthin (1929), of Michigan University, emphasizes that, according to the data of the U.S.A. Census Reports, "the increase in the average longevity is due to the saving of life through the prevention of extrinsic pathological death in the earlier decades of life, but that there has been no extension of the normal or biologic life limit" (pp. 166-7) . . . "It is therefore neither possible nor probable that the average longevity can be raised to the heights prophesied by the over-zealous and very inaccurate advocates of life extension" (p. 170). Warthin in this case refers to an extension of life up to 125-140 years.

Metchnikoff (1907), on the contrary, says that "we may predict that when science occupies the preponderating place in human society that it ought to have, and when knowledge of hygiene is more advanced, human life will become much longer" (pp. 226-7).

Prof. Fisher (1923) concludes that "it would be surprising if the future should not witness a further lengthening of human life, and at an increasing rate. Of course, there is a limit to the further increase of human life, but there is good reason to believe that the limit is still far off" (p. 103). . . . "If . . . notwithstanding all existing chances of death, it is possible for some persons to live beyond 120, the chances in the future for a larger proportion of such persons will be materially improved" (p. 112).

Prof. Simms (1946), of Columbia University, states that "there is at the time no proof for or against the possibility that we can some day extend our active life an extra one hundred or two hundred years with retention of youthful health, intelligence, and appearance" (p. 24).

A scientific and medical investigation of the span of centenarian life might, as already mentioned, be of great importance from several points of view. For example, histories of two long-lived families described by Weber

(1919) indicate heredity as one of the causative factors of longevity. His tables on pages 21 and 23 give the respective data of the span of life of the brothers and sisters in these two families. These tables are abbreviated and pooled in Table III of the present paper.

### A Social Problem

The question of centenarians is closely connected with one of the gravest social problems of our days—namely, the growing proportion of old people in the population. In the excellent report of the Nuffield Foundation (Rowntree, 1947) this is illustrated by a table (p. 3) prepared by W. A. B. Hopkin, a member of the staff of the Royal Commission on Population. The abbreviated data from this table are given in Table IV of the present paper. From

TABLE IV.—Population of England and Wales by Three Main Groups (thousands). (Abbreviated from Rowntree's Report, 1947, p. 3)

Year	Age			Total Population
	Under 15	Men, 15-64; Women, 15-59	Men 65, Women 60, and over	
1944 .. ..	8,671	28,382	5,396	42,449
1954 .. ..	9,086	28,080	6,143	43,309
1964 .. ..	8,440	27,894	6,811	43,145
1974 .. ..	8,081	26,692	7,804	42,577
1984 .. ..	8,043	25,547	7,944	41,534
1989 .. ..	7,886	25,071	7,848	40,805
1994 .. ..	7,679	24,872	7,504	40,055

this table it is estimated that by 1989 the number of old people of pensionable age will equal the number of children, while by the same year the number of persons of working age will be approximately three millions less than in 1946. The report adds (p. 2): "The trend revealed in Mr. Hopkin's figures may, however, be even more pronounced than the table suggests; for other authorities, among them the Registrar-General, have forecast that as early as 1971 the number of persons of pensionable age may equal, or even exceed, the number of children."

This position is considered to be very serious because at present helpless old people become a great burden on the younger working population. Such a position, however, will not necessarily be the same in future, as Metchnikoff and Fisher emphasize. It is probable that medicine and science will not only add years to the life of an old man but simultaneously will conserve his physical and mental vigour for a longer period. "One result of lengthening life will be a greater utilization of accumulated experience. We shall have less immaturity in judgment. . . . It will give to society a body of old yet hale men of experience, whose influence and worth cannot be measured" (Fisher, 1923, p. 111).

### Conclusions

In the data recorded in the Registrar-General's Office the certificates of birth of centenarians have not been checked, and therefore their age can be accepted only with some reservation. Since, however, these data were investigated during the latest period of 16 years, and as the figures investigated were constant in character, their value and reliability are probably still considerable.

According to these data, in England and Wales per 20 millions of male or female population there were each year on the average 17.7 male and 71.4 female centenarians in the period 1930-7, and 18.3 and 83.4 respectively in the period of 1938-45. Thus, unexpectedly, their incidence was regular and not very exceptional, and more women had a long span of life than men.

There was a statistically significant increase of female centenarians during the last eight years as compared with

TABLE III.—Two Long-lived English Families, Alexander and Kempe (Weber, 1919, pp. 21, 23)

Alexander (Quakers)			Kempe

\* Those marked by an asterisk were still alive at the time of publication of Weber's book.

a previous period of eight years, while a small increase in male centenarians in the last period was not significant.

During these periods the longest human lives recorded were 109 and 112 years, and this fact is in approximate accord with the conclusions reached by previous critical investigators for periods earlier than 1930.

Thus, theoretically and potentially, a span of life of 109–112 appears to be possible for a human being. As, however, the exceptional cases of longevity of human beings have occurred during the present time, when the process of ageing is abnormal, there is some possibility that the span of human life might be further extended when the process of ageing becomes a normal one.

There are some indications that the genetic factor is one of the causal factors of longevity.

Taking into consideration the primary aim of gerontology to make old age stronger and healthier, and not only longer, the prophecy of Metchnikoff and Fisher may be right—that in this way the *useful* period of human life might be extended and the community benefit by a greater utilization of the accumulated experience and wisdom of older people.

It is most desirable that scientific and medical investigation of cases of centenarians should be carried out by research workers.

I wish to express my gratitude to the Registrar-General and his Office, in particular to Mr. A. A. Dodge, for supplying me with all necessary data concerning published and unpublished cases of centenarians.

## Medical Memoranda

### Relief of Pain in Childbirth

While acting as house-surgeons in Maryfield Hospital, Dundee, we obtained permission to try the administration of phenobarbitone and rectal ether for the relief of pain in childbirth as outlined by C. B. Lull and R. A. Hingson (1945).

The technique adopted was to give the patient a 5% sodium bicarbonate enema on admission. When her pains began to make her uncomfortable she was given 3 gr. (0.2 g.) of phenobarbitone, which was repeated in 1½-gr. (0.1-g.) doses as required. As soon as the pains became distressing—usually towards the end of the first stage—2½ oz. (70 ml.) of ether in 1½ oz. (42 ml.) of olive oil or mineral oil was administered rectally. This enema was given slowly, with the patient on the left side, care being taken to pass the catheter above the presenting part. This makes the patient feel very drowsy within a few minutes, the effect lasting for two to four hours. The rectal ether can be repeated in two hours if the effect is wearing off. If the patient is exhausted or it is suspected that the labour will be prolonged, 2 dr. (3 ml.) of paraldehyde may be added to the rectal instillation to produce a deeper sedative action.

**Results.**—In our series of twenty-five cases, mostly of primigravidae, we found that all received relief from this

treatment. All slept between their pains and also used their pains well. The multiparae admitted it was the easiest labour they had had, several of them requiring to be reassured that their baby had been born.

**Actions on the Mother.**—(1) Restlessness and distress were relieved so that they relaxed well between pains. They were in a state which was highly responsive to suggestion, and obeyed the instructions given by the attendant. (2) The pains continued with the strength and frequency which would have been expected if rectal ether had not been administered. (3) The pelvic floor relaxed well and the head advanced quickly. (4) The third stage was short, the average duration being 12 minutes, and after expulsion of the placenta the uterus contracted firmly and there was no case of post-partum haemorrhage. (5) The patients co-operated so well during the birth of the head that only three out of twenty-five required a perineal stitch. (6) There was no increase in the forceps rate.

**Effect on the Foetus.**—Every child cried immediately at birth, and was in no way affected by the sedation.

In conclusion, we found this method very satisfactory; it is safe for both mother and child, it is easy to administer, and it does not prolong labour.

### Safety-pin in Larynx for Five Weeks

The presence of an open safety-pin in the larynx of a 2-year-old child for over five weeks seems unusual enough to warrant record.

#### CASE REPORT

On April 13, 1946, a practitioner was called to see a small boy aged 2 who was reported to have had some dyspnoea during the night. He was over-quiet and pointed to his throat. He cried when the throat was examined. The practitioner described the cry as "croupous and husky." Nothing abnormal was found in the throat or chest. The temperature, pulse, and respirations were normal. The next day there was some dyspnoea and a croupous distressing cough. Laryngeal diphtheria was suspected; 800 units of antitoxin were given and the child was sent to a fever hospital. He had been immunized previously.

On admission he was given 40,000 units of antidiphtheritic serum, but the medical superintendent did not consider it was a case of diphtheria; he suspected an early pneumonia, though signs in the chest were absent. The respiration was increased and there was difficulty in getting him to take food. Negative swabs were obtained from the nose and throat on April 14, 15, and 16. The patient was fairly comfortable till April 24, when symptoms of obstruction arose. He was put in a steam tent, but did not improve, and in view of the increasing dyspnoea tracheotomy was performed the next day. During the following two weeks various attempts to remove the tube were made, but without success.

I first saw him on May 10. He was quite unable to breathe through the larynx. There was no cry. An attempt at laryngoscopy with inadequate instruments showed a mass in the larynx. The child was transferred to a nursing home and a direct laryngoscopy was performed on May 21. The larynx was filled with a mass of granulation tissue. When this was probed a foreign body was seen. It looked like a coin, but gentle traction showed that it was fixed, especially at the posterior end. The anterior end was gently pulled on and the body removed. It proved to be an open brass safety-pin 7/8 in. (2.2 cm.) long. During the next fortnight the tube was changed daily, but there was still no airway through the larynx. Direct laryngoscopy showed the swelling to be much smaller, and the left vocal cord was visible. A few days later he cried for the first time, and in a day or two began to say a few words, and was soon talking freely, with the tube corked. The tube was finally removed on June 20, a month after the operation. A week later he went home looking fit and well and talking freely and, for his age, clearly. I saw him again in October and found him quite well, and breathing and talking normally.

I am indebted to the doctors in charge of the case for details of the early history.

E. S. BURT HAMILTON, F.R.C.S.Ed.

## Reviews

### RHEUMATOLOGY

*Medical Disorders of the Locomotor System, Including the Rheumatic Diseases.* By Ernest Fletcher, M.D., M.R.C.P. (Pp. 625; 262 figures. 45s., plus 8d. postage.) Edinburgh: E. and S. Livingstone. 1947.

This admirably documented and illustrated textbook of the chronic rheumatic diseases, including a chapter on medical diseases of bone, provides many references to the large amount of work being done on the subject, but the reiteration of "perhaps it may be" or "we suspect that" shows how obscure the subject is and how incomplete our knowledge. The problematical aetiology of these conditions precludes satisfactory classification, and it is possible to arrange them only in broad clinical divisions. The author has entrusted certain sections to other specialists—for example, that on fibrositis to Dr. Copeman and on radiology to Dr. Campbell Golding—but for the most part he writes from his own experience backed by study of the literature.

After preliminary chapters on anatomy and physiology, general aetiological factors, and radiology the author discusses acute rheumatism, and emphasizes the value of Coburn's massive doses of salicylates and sulphonamide prophylaxis as practised in the American Army. He then considers its relationship to chorea and the possibility of acute rheumatism and rheumatoid arthritis being variants of the same disease; his observations on the aetiology of the latter reveal how difficult the problem still is. He advocates the sanatorium regime for the treatment of rheumatoid arthritis and gives a full account of gold therapy. He then discusses the nodule and its significance, minutely describing the variety with the necrotic centre, which is characteristic of both rheumatism and rheumatoid arthritis. Writing of osteoarthritis he does not favour the infective theory of its origin. The injection of joints with lipiodol may be beneficial. The author attaches more importance to osteoarthritis of the spine as causing obscure pain than do some authorities.

Discussing fibrositis Copeman points out that the establishment in the course of any infection of "trigger points," which may in some cases persist and be reactivated, may explain its manifestations. He also describes his investigations into tender herniated fat lobules. The specific arthritides and gout are adequately discussed and there are excellent chapters on the possible causes of sciatic and brachial neuralgia, for which the author on the whole prefers conservative treatment. There are full discussions on pain and stiffness in the shoulder, back, and foot, and a final chapter on physical treatment. Spa treatment is only briefly mentioned for fibrositis and not at all for chronic gout. This book is a credit to British rheumatology and indispensable to specialists in the subject.

R. G. GORDON.

### SYMPATHETIC NERVE INFILTRATION

*Les Infiltrations du Sympathique. Techniques.* By Maurice Luzuy. Preface (Pp. 200; 24 figures. 375 francs.) Paris: ...

Dr. Luzuy records in this book his study of the effects of procaine (novocain) on sympathetic nerves. He discusses in detail the technique of and indications for sympathetic block, and the deductions which he has made and applied to the theory of sympathetic, cardiovascular, and visceral physiology and pathology. Prof. Leriche contributes a happily worded preface—and most suitably, for the methods and opinions of the book correspond closely to his own.

The technique described for the infiltration of each sympathetic area accords in general with the usual Anglo-American practice, but the author advocates a lateral path for the approach to the stellate ganglion, an anterior method for the infiltration of the carotid sinus, and Cotte's transvaginal approach for the injection of the hypogastric ganglion. Arnulf's method of infiltrating the preaortic plexus from the root of the neck, fully described, is not yet widely practised in this country. The first section of the book covers the effects of trauma. The author ascribes the efficacy of local infiltration anaesthesia in permanently relieving sprains of joints to an interruption in those

antidromic sympathetic vasodilatation influences which are said to be responsible for the symptoms of a sprain, and he attributes the later effects of trauma, including post-traumatic cyanosis, oedema, osteoporosis, and hypercalcification, to sympathetic disturbance and treats them successfully also by sympathetic block, though at a higher level, by infiltration of the appropriate sympathetic ganglion. The field covered by the second section, the application of sympathetic block to vascular disease, is that in which, more than in any other perhaps, surgery has been advanced by the school of Leriche, and Dr. Luzuy's arguments are well considered.

The evidence offered in the third section of the effect of splanchnic block in congenital pyloric stenosis, megaduodenum, acute dilatation of the stomach, gastric ptosis and atony, peptic ulcer, gall-bladder stasis, constipation, intestinal obstruction and strangulation, acute pancreatitis, and diabetes will not unreservedly convince all readers; and the records of the six patients treated by infiltration of the preaortic plexus for coronary disease do not fully prove the efficacy of that measure. The book ends with a description of the method of intravenous procaine injection and its success in the treatment of asthma. As Prof. Leriche explains in his preface, Dr. Luzuy is an enthusiast, and this book gains by that quality in vivacity what it loses in detachment.

IAN AIRD.

### THE ROTUNDA

*The Rotunda Hospital, 1745-1945.* By O'Donel T. D. Browne, M.B., M.A.O., F.R.C.P., F.R.C.O.G. (Pp. 296; 44 illustrations, a synopsis, and graph. 42s.) Edinburgh: E. and S. Livingstone. 1947.

Bartholomew Mosse opened the Dublin Lying-in Hospital for Poor Women on March 15, 1745. He died suddenly in 1759 at the age of 47. He had envisaged a "large impressive and suitable place of entertainment" alongside the hospital, but did not live to see the completion of the Round Room in 1767. From then on the name "Rotunda" was adopted, and the Rotunda Hospital embarks next week on the bicentenary celebrations which the war postponed.

Dr. O'Donel Browne has given a detailed account of the development of the hospital and of the contributions to obstetrics made by its Masters, setting his local theme against the wider background of the general history of midwifery. His book has six sections, each with its own references: the first 100 years; the second 100 years; the struggle against puerperal fever; operative midwifery; anaesthesia and gynaecology; eclampsia. This arbitrary division is unfortunate, and a great deal of dull detail makes the first two parts of the book heavy going. It involves repetition in each section, and it makes it difficult to assess the standing of any one Master, since his activities and the changes he brought about may be discussed under six different headings. This criticism may have been made at an earlier stage and may account for a final chapter listing the outstanding Masters. No one would quarrel with Dr. Browne's view that Mosse was the greatest Rotunda Master, and Fielding Ould, Clarke, Labatt, Collins, Macan, Smyly, and Tweed worthy successors. It is good to know that there were once 72 gallons of whiskey in one hospital, and at a cost of only £9 15s., but salaries and allowances for officers and servants are of less interest, and no one can make the minutiae of redecorations and extensions lively reading.

The section on eclampsia is better, and so is that on puerperal fever, though it is difficult to justify the equal emphasis on Oliver Wendell Holmes and Ignaz Semmelweis. Discussing operative midwifery and gynaecology, Dr. Browne has assessed fairly those fields in which the Rotunda advanced steadily and those in which it lagged through excessive conservatism. In his account of the application of anaesthesia to midwifery Dr. Browne has been uncritical. For much of his material he has obviously gone back to the original documents. Here he has copied a venerable error. "Simpson was knighted in 1870. His friend, Sir Walter Scott, wrote advising him that he should have as coat-of-arms 'a wee naked bairn' with the inscription: 'Does your mother know you're out?'" Sir Walter Scott died in 1832. These are minor criticisms of a book so well produced that it deserved better proof-reading. There may be argument about Dupey or Dupuy and about Ségault or Sigault, but the first Assistant Master to perform a successful caesarean hysterectomy in a patient's home ought not to be Bagot on one page

and Baggot later. There is probably nothing significant in the history of the Rotunda not included in Dr. Browne's story or in his excellent synopsis. His illustrations are numerous, well chosen, and well reproduced. Medical historians will find his book useful, but a shorter version with more carefully selected and differently presented material would appeal to a much wider circle of readers.

### THE N.H.S. ACT

*The National Health Service Act, 1946.* Being the Complete Text of the National Health Service Act, 1946, with an Introductory Explanation of the Act. By J. A. Scott, M.D., D.P.H. Together with an Index to the Act compiled by, H. A. C. Sturgess. (Pp. 93. 9s. 6d.) London: Eyre and Spottiswoode (Publishers), Ltd.

Two-thirds of this volume reproduce the text of the Act, the remaining third being shared equally by an introductory section, a summary of the Act, and an index to the Act. In the introductory section the author briefly considers the Government's social legislation for preventing individual poverty, and he sketches the main principles of the National Insurance, the National Insurance (Industrial Injuries), and the Family Allowance Act. Under the title "The planning proposals of the medical profession" he includes a paragraph on the B.M.A. proposals for a General Medical Service for the Nation and a summary of the Draft Interim Report of the Medical Planning Commission (1942). There follows a section in which health centres, including the model centre suggested by the Commission, are discussed at some length, and with the author's personal observations on the health centre concept thrown in. He stresses two trends in modern medicine: first, a strong desire to combine preventive and therapeutic work, and secondly a tendency for child health and maternal care to become separate specialties in the hands of different sections of the profession. In discussing the staffing of the "public health" part of health centres he contemplates that many of the whole-time officers engaged in maternity and child welfare and school medicine will wish to continue with their present work, and to that extent both general practitioners and specialists may only gradually have the opportunity to take part in the work, but "there is no inherent reason why the general practitioner with suitable experience should not undertake it, as he wishes to do." Notes on (1) the areas of Regional Hospital Boards, (2) the regional hospital surveys, and (3) the original White Paper on a national health service issued by the Coalition Government, in this somewhat topsy-turvy order, complete the introductory section.

In Part II he summarizes objectively and concisely the main provisions of the Act. It will be welcomed by those who seek a broad picture of the scheme. For the most part he avoids the pitfalls inherent in the translation of the Act's legal terminology into lighter and less tiresome reading. In two minor instances, however, the summarized version may be misconstrued in relation to the text of the Act. On page 25 it is stated: "Lists of medical practitioners providing general medical services will be published, and every doctor (who is not a paid assistant) in practice before the appointed day who duly applies is entitled to have his name on the list." The right of the practising doctor to have his name on the list is limited to the list of "the Executive Council for any area in which he is practising." On page 26 it is stated: "It is a duty of every Executive Council to arrange for the supply of drugs, medicines, and appliances from health centres or otherwise to everyone in the area entitled to general medical and dental services." The terms of clause 38 of the Act do not extend to everyone in the area entitled to general medical or dental services but to persons in the area receiving those services. From clause 38 (2) it appears that the Executive Council's arrangements are to ensure for those persons the supply of "proper and sufficient drugs and medicines and prescribed appliances" if ordered by the medical practitioner rendering general medical services (or by the dental practitioner in the case of general dental services). The index is masterly and certainly the most valuable part of the book.

The 1947 edition of the *Medical Register* has recently been published (22s., post free). Particulars given in tabular form reveal that on Dec. 31, 1946, there were 76,292 names on the Register—nearly half as many again as in 1927, when there were 53,591. In 1946 2,237 names were added and 1,092 removed for various reasons.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Diseases of Children's Eyes.* By J. H. Doggart, M.A., M.D., F.R.C.S. (Pp. 288. 42s.) London: Henry Kimpton. 1947.

After discussing principles of examination, anatomy, developmental errors, and methods of treatment, the author considers eye diseases in children and their treatment. Many coloured illustrations.

*Old Age and How to Make the Best of It.* By R. A. Bennett, M.D. (Pp. 23. 2s. 6d.) Bristol: John Wright and Sons. 1947.

Comments, with quotations from the classics, on growing old.

*Current Therapies of Personality Disorders.* Ed. by Bernard Gluck, M.D. (Pp. 296. 17s. 6d.) London: William Heinemann. 1946.

Evaluation of various methods of psychotherapy by a number of different authors.

*History of the Abolition of State Regulation of Prostitution.* By Mmc. Legrand-Falco. (Pp. 30. 1s. 6d.) London: The Association for Moral and Social Hygiene. 1946.

The history in France is referred to particularly.

*Laboratory Instructions in Biochemistry.* By I. S. Kleiner, Ph.D., and L. B. Dotti, Ph.D. 2nd ed. (Pp. 245. 12s. 6d.) London: Henry Kimpton. 1946.

A manual of practical biochemistry for use in the laboratory, with space for notes.

*Nozioni di Immunologia.* By Prof. E. Carlinfanti. (Pp. 760. No price given.) Milan: Istituto Sieroterapico Milanese Scrafino Belfanti Editore.

An account of antigen-antibody reactions in diagnosis, therapy, and prophylaxis.

*Recopilacion de Leyes, Reglamentaciones, Decretos y Resoluciones Sanitarias.* Published by the Argentine Ministry of the Interior, Direccion Nacional de Salud Publica. (Pp. 928. No price.) Buenos Aires: Imprenta de la Camara de Diputados. 1945.

Laws relating to public health in Argentina.

*Jubilee Volume.* Dedicated to Emil Christoph Barell by the Scientific Workers of the Roche Companies. (Pp. 466. No price.) Basle: F. Hoffmann-La Roche. 1946.

Includes papers on the synthesis of certain vitamins and other compounds, on the furans, and on antibiotics.

*Dolores Mortales.* By Dr. Miguel Lopez Esnaurizar. (Pp. 65. \$15 M.M.) Uteha, Mexico: Editorial Conzalez Porto. 1947.

A monograph on the conduction of pain impulses by the autonomic nervous system.

*La Douleur.* By Dr. Paul Chauviard. (Pp. 128. No price.) Paris: Presses Universitaires de France. 1947.

A study of pain as a protective mechanism.

*Food Inspection Notes.* By H. Hill, F.R.San.I., and E. Dods-worth, M.R.San.I. 2nd ed. (Pp. 125. 6s.) London: H. K. Lewis. 1947.

A summary for public health students of the properties of healthy and diseased foodstuffs.

*The Problem of Fertility.* Ed. by Earl T. Engle. (Pp. 254. 21s.) Princeton University Press (London: Geoffrey Cumberlege). 1947.

A collection of papers on the factors affecting fertility in man and in animals.

*Textbook of Surgical Treatment.* Ed. by C. F. W. Illingworth, C.B.E., M.D., Ch.M., F.R.C.S. 3rd ed. (Pp. 644. 32s. 6d.) Edinburgh: E. and S. Livingstone. 1947.

Includes new sections on wound infections, penicillin in surgery, plastic surgery, facio-maxillary injuries, the use of protein in surgery, and the anticoagulant treatment of thrombosis.

*Notes on Clinical Laboratory Methods* By the Standing Committee on Laboratory Methods, University of Glasgow. 5th ed. revised. (Pp. 95. 3s. 6d.) Glasgow: John Smith. 1947.

An outline of laboratory methods in clinical medicine for medical students.

## THE SPREAD OF STAPHYLOCOCCAL INFECTION

It is a truism that the control of epidemic infection must be based on exact knowledge of the paths of its spread. These have been fairly well known for many years in connexion with some infections. At the opposite extreme they remain conjectural even now in the case of certain virus diseases, because the presence of the agent in different materials cannot be demonstrated by any simple test. A special position is occupied by infections due to common bacteria of wide distribution, because their mere presence is not necessarily connected with a particular epidemic. Unless the epidemic strain has some special characteristic, it is impossible to decide whether, for instance, a carrier of the species concerned is to be incriminated. It is here that the definition of individual "types" within species has been found so valuable. The separation of such types, and epidemiological studies based on them, form a profitable pursuit in which workers in this country have led the world. Almost all that we know with certainty about the epidemiology of streptococcal infections is based on the determination of types defined by the late Frederick Griffith. McLeod's types of *C. diphtheriae* have also been helpful, and recently the phage typing of *Salm. typhi* and of *Staph. aureus* have enabled other workers to trace the sources of epidemics which could not otherwise have been elucidated.

Perhaps the most forbidding task of all has been to disentangle the migrations of staphylococci, particularly under institutional conditions. These organisms are so widespread that it might seem impossible to trace them to their source, even under conditions of epidemic spread. An opportunity for attempting this is furnished by outbreaks of pemphigus neonatorum among infants in maternity homes. These are not uncommon, and they are usually followed by wholesale swabbing and the resultant discovery of numerous carriers among patients and staff. Anyone who, having obtained such information, has then been somewhat at a loss to know how to interpret or act on it will be grateful to V. D. Allison and Betty C. Hobbs, whose paper appears in the opening pages of this issue, for having pursued such an investigation so thoroughly as to reach definite conclusions about the mode of spread of the epidemic. To enable such conclusions to be drawn, typing of the strains isolated was essential. The method employed was serological, based on the original types defined by Cowan, and the identity of a number of strains defined by this method was confirmed by phage typing.

This study was pursued over a period of two years in a large maternity home at Cardiff, and during this time in

three outbreaks there were 107 cases of pemphigus and 21 of staphylococcal conjunctivitis. The majority of cases in each outbreak were due to a single serological type: possible sources of infection could therefore be identified with some certainty. The organism concerned was found to be exceedingly widespread. It was recovered sometimes from air or dust, and from blankets and clothing. Among human sources the mothers could be excluded in the majority of cases, only 6 out of 15 being found to harbour the same type of staphylococcus. On the other hand, swabbing of the nursery staff on several occasions revealed a large proportion of nasal carriers, many of whom were infected with the same type as that producing pemphigus in the infants. Whether this state of affairs was a cause or an effect might have been uncertain had not swabs been taken from the staff at the beginning of the third epidemic, when only a single case of pemphigus had occurred. At this early stage no fewer than 18 (37.5%) of the nursery staff were already nasal carriers of type 1 *Staph. pyogenes*, the cause of the epidemic which followed. As the authors remark, this observation strongly suggests that a "build-up of nasal carriers of a potentially infective strain occurs among the staff before the appearance of cases of pemphigus." If this is indeed the mechanism underlying such outbreaks, it is at least practicable to define appropriate precautions. It is noteworthy that among the staff there was no skin carrier who was not also a nasal carrier; in other words, the ultimate source in the carrier is nearly always the nose, and the most elementary of all precautions is to obviate contamination of the hands from that source. Is it yet generally understood among nurses that the use of a handkerchief should be followed by thorough washing of the hands?

Other measures which may materially assist in protecting infants from infection are discussed in this paper. Over crowding, which was evidently a factor in the first of the outbreaks described here, must obviously be avoided, and good ventilation and lighting are necessary. Measures to allay dust are important, as in cross-infection of almost all kinds; in particular ordinary dry sweeping is to be condemned and a vacuum cleaner or damp dusting substituted. Then there are many technical details connected with the nursing care of infants which require regulation with the possibilities of cross-infection in mind, such as the sterilization of baths, and the use of separate toilet outfits and towels for each infant. The highly trained nurse will instinctively conform to such practices; for pupils the rule need to be precise and rigidly enforced. The authors make the interesting suggestion that infants would perhaps be better off with their mothers than congregated in a room separate from them, a system which can be commended from other points of view (see page 20). The treatment of carriers with sulphathiazole snuff has proved disappointing, and it is apparently concluded that attempts to clear up carriers by such means are not worth while. The addition of calcium penicillin to sulphathiazole used as snuff greatly reinforces its action, and the use of this mixture is worth considering if in any individual case it is deemed important to abolish the carrier condition. This paper with its very practical conclusions will be welcomed by those who have had to deal with such troubles in maternity

homes. So elaborate a form of investigation is rarely possible, but when once carried out with such thoroughness it almost removes the necessity for further efforts on the same lines.

## NEONATAL INFECTIONS

The stress which is now placed upon the prevention of ill-health, especially in young children, has caused renewed attention to be given to certain diseases and abnormalities, which in the past have received only sporadic consideration in medical literature and have seldom aroused more than a local and temporary interest. Neonatal infection is a case in point; and the recent Report<sup>1</sup> prepared by a highly competent subcommittee of the Scientific Advisory Committee to the Department of Health for Scotland is an important document, not only for its detailed and very practical recommendations for the prevention of such infections but because it focuses attention upon the conditions which endanger newly born babies, especially in maternity institutions, and upon the characteristic features of infective processes in the early weeks of life. There is no period in the whole life of man, from fertilization of the ovum to old age, when he is safe from the threat of bacterial assault; but the circumstances in which the warfare begins and is pursued, the constitution of the armies engaged, and the probable course of the battle vary materially from phase to phase of the person's life. In so far as neonatal infection is concerned it is well known that unhygienic conditions in the baby's environment, overcrowding, faulty nursing care, and the contact of the child with infected adults are the most important sources of danger; and it is unfortunately true that despite anxious efforts by the medical staffs and lay committees of maternity institutions to reduce these risks in the nurseries and wards of their hospitals the babies born in many institutions are seriously threatened. Most of our maternity hospitals were built at a time when it was the custom to house the babies in large nurseries, where the danger of cross-infection is considerable; and the increased demand by mothers to have their babies in hospital has accentuated conditions of overcrowding. But it is probable that faulty nursing care is a greater danger than faulty architectural design. Such a statement should not be interpreted as a criticism of the student nurses, who are for the most part conscientious, enthusiastic, and hard-working; indeed, our sympathy goes out to them in their daily struggle to achieve the impossible. Insufficient in numbers, harassed by examinations which stress theoretical book knowledge rather than practical proficiency, and sometimes irritated by rules and regulations long outdated, these women are driven to adopt a nursery technique which places a premium upon speed. The Report states that the preventive measure of greatest importance in dealing with neonatal infection is the routine observance of an orderly and unhurried basic nursing technique by a staff adequate in number and quality; and it recommends that a ratio of two nurses to three cots should be aimed at as a minimum in the nurseries. In the larger maternity hospitals and units there should be a basic permanent staff of trained nurses,

especially in the units for premature infants, sick infants, and infected infants, and there should be a trained nurse always on duty and an experienced sister, or sisters, in charge. At least one-third of the nursery staff should consist of permanent trained personnel, the remainder being trainees. These recommendations are in general agreement with those put forward by a subcommittee of the British Paediatric Association on neonatal mortality and on arrangements for newly born babies in maternity hospitals.<sup>2</sup> During the present shortage of nurses it is suggested that nursery nurses be recruited, where possible, as helpers in the nurseries, with appropriate scales of remuneration. Useful suggestions are made regarding the training of midwives, and Appendix 2 provides a detailed description of nursery technique as practised in the Aberdeen Maternity Hospital. It is interesting to compare this Appendix with the technique adopted by Beryl Corner.<sup>3</sup> A suggestion likely to meet with the approval of paediatricians is that part of the training of a sick children's nurse might be obtained in the nursery of a maternity hospital or unit for a period of, say, three months. In regard to architecture, the Report recommends that large nurseries should be replaced by a suite of smaller wards, preferably containing from four to six cots each. Special provision is needed for (a) sick infants (10 cots per 100 maternity beds); (b) premature infants born in the hospital or admitted from the district (10 cots per 100 maternity beds); and (c) the isolation of infants suffering from infective conditions (5 to 10 cots per 100 maternity beds). Some of these special wards should be capable of holding 4 cots each, and some should be single cubicles. It may be questioned whether the Report goes far enough in this section, and a strong case can be made by those who hold that mothers should have their babies beside them: when this is done "with simple precautions not only is the danger of neonatal infection less than it otherwise would be, but breast feeding and the relationship between mother and child are firmly and safely established in a physiologically natural manner."<sup>4</sup>

The most dangerous of the commoner types of neonatal infection are pneumonia and epidemic diarrhoea; but even "minor" infections such as conjunctivitis, septic spots on the skin, and the common cold are liable to develop into more serious infections, and are a source of danger to other infants. The pathologists of the two maternity hospitals mentioned in the Report considered that at least 30.7% and 16.1% of the total neonatal deaths in their hospitals were due to infection. These conclusions are in line with an earlier report by J. N. Cruickshank,<sup>5</sup> who in a survey of 800 neonatal deaths in a maternity hospital found that 29.75% were caused by infection. Premature infants, and those who suffer an injury at birth or neonatal asphyxia, are especially liable to fall victims, and the infection may then be a terminal complication. The clinical recognition of some types of neonatal infection presents difficulties, which probably accounted for the fact that in the two series of cases

<sup>2</sup> *Arch. Dis. Childh.*, 1943, 18, 62, 159.

<sup>3</sup> *Proc. roy. Soc. Med.*, 1946, 39, 383.

<sup>4</sup> Spence, J. C., *British Medical Journal*, 1947, 1, 125.

<sup>5</sup> *Med. Res. Cncl. Sp. Rep. Ser.*, No. 145, 1930, London.

mentioned above the diagnosis was made during life in only 16.1% and 17.6% respectively. There is, however, a general feeling among paediatricians that the higher figure is a more accurate estimate of the prevalence of neonatal infection in institutions.

Other subjects which receive consideration are the importance of breast feeding; the value of mothercraft instruction, and of better co-operation between hospital, health visitor, and family doctor; the paediatric staffing of maternity hospitals; record keeping and annual reports; the milk kitchen; and the prevention of infection when artificial feeding is essential.

## SURGERY OF THE GALL-BLADDER

It is a salutary if somewhat humiliating thought that in spite of the advancement of surgery the gall-bladder continues to present many unsolved problems. Thanks to a combination of more accurate diagnostic methods, more detailed planning of pre-operative treatment, improved technique, and the development of preventive measures against post-operative complications, the mortality of gall-bladder operations has fallen in a period of 20 years from about 4% to 1% or less. Nevertheless, there is still no agreement on whether a gall-bladder should be removed from the fundus downwards—as recommended by such a sound and experienced surgeon as Allen,<sup>1</sup> of Boston—or from the ducts upwards. The latter method is that usually taught in this country—the former probably the more commonly practised. On page 11 of this issue Love describes a refinement of cholecystectomy based on the partial removal of the gall-bladder, combined with electrocoagulation of the residual strip left on the liver bed, which he terms diathermy dissection. This procedure allows the raw area of the liver bed to be covered either directly by peritoneal flaps or by a pad of omentum or falciform ligament. If this effects, as is claimed, sufficient sealing of blood and bile vessels to prevent post-operative drainage there is no doubt the consequent avoidance of chest complications would render cholecystectomy a safer procedure.

The author's account in the same article of an abnormal duct from the gall-bladder to the liver draws attention to the well-known multiplicity of variations in the anatomical arrangement of the bile ducts and accompanying vessels, which, combined with difficulty of access, makes the more mechanical side of gall-bladder surgery so difficult. The recent spate of articles on repair of damaged bile ducts is unfortunately not all the result of war injuries. Here again the many ingenious methods of anastomosis described show that no general agreement prevails. Another important practical consideration arises from Love's article: should the common bile duct be opened as a routine during cholecystectomy or not? The pendulum appears to be swinging towards a more conservative approach to this problem, and most surgeons would probably consider a routine cholangiogram during operation an unnecessary procedure.

Battles are still being fought over the aetiology of cholelithiasis. The advocates of stasis and infection have recently met a doughty opponent in Robertson,<sup>2</sup> of the Mayo Clinic, who has produced a convincingly argued hormonal (sex-hormone) theory for gallstone formation. The contribution from Majoor and Suren on page 8 of this issue exhibits another aspect of this evergreen subject and may throw light on it. These Dutch workers, collecting their information during the difficult days of the

"occupation," draw their interesting deductions from their post-gastrectomy cases, in some of which gallstones have developed within six months to three years after operation. Their surmise that the interruption of normal duodenal flow leads to such changes in biliary physiology that cholesterol is precipitated in abnormal quantities has both practical and theoretical significance. The biliary apparatus and its contents—physiological and pathological—still offer a wide field for research.

## ANTISEPTIC TREATMENT

It is a source of enduring wonder to anyone who has followed the development of bacterial chemotherapy in the past fifteen years that the major forms of septic infection can now be treated more successfully than the minor. In the presence of a spreading cellulitis or septicaemia the indications for treatment are clear, and the results almost uniformly good. On the other hand, local septic infection, whether in a wound or elsewhere, cannot be overcome with anything like the same facility by the same or any other means. There are several reasons for this, among them the frequent presence of penicillin-resistant types of bacteria, such as Gram-negative bacilli, the relative inactivity of sulphonamides in wound exudates, and the relative inactivity of the bacteria themselves, their susceptibility to either of these agents being greatest only during active multiplication. Used intelligently, and only in the presence of susceptible infection, penicillin is of course an ideal antiseptic, but it is by no means applicable to every case, and the search continues for some other agent which will fill the gap left by its deficiencies.

A very considerable variety of antiseptics is still being experimented with, and to judge by the present literature on the subject the field is as open as it was fifteen years ago, though there is now a much firmer conviction that such treatment, properly applied, can be effective. Most of this literature is American, and it deals with almost every conceivable type of substance except the acridines. It is not easy to understand why workers in the U.S.A. disregard proflavine and the newer compounds such as 5-aminoacridine, the use of which for combating sepsis has received strong support from sources in Great Britain, the British Army, and Australia. It would be interesting if the mixture<sup>1</sup> or compound<sup>2</sup> of proflavine and sulphathiazole which has found favour here were included in some of the trials now proceeding in the U.S.A. An example of this type of work is that described by E. L. Howes,<sup>3</sup> who submitted various antiseptics first to tests for toxicity, which included addition to tissue cultures, application to the eye, intramuscular and intraperitoneal injection, and observations on effect on wound healing. Zephiran, parachlorophenol, and tyrothricin were eliminated from further trials as being too toxic. The substances surviving this stage were penicillin, streptomycin, and "sulfamylon" (better known as "marfanil"). These were submitted to tests of bactericidal activity and finally to clinical trial for wound treatment.

The technique employed for testing bactericidal activity in the presence of blood was the application of the antiseptic solution on a piece of filter paper for ten minutes to a heavily inoculated blood agar plate previously incubated for three hours. This method is open to criticism, because its results do not reflect capacity to kill various species of bacteria within ten minutes, as the author appears to suggest, but rather diffusibility into the medium and subsequent bacteriostatic action. As judged in this way

<sup>1</sup> *Ann. Surg.*, 1945, 121, 412.

<sup>2</sup> *Surg. Gynec. Obstet.*, 1945, 80, 1.

<sup>1</sup> McIntosh, J., and Selbie, F. R., *Lancet*, 1944, 1, 591.

<sup>2</sup> McIntosh, J., Robinson, R. H. M., and Selbie, F. R., *ibid.*, 1945, 2, 97.

<sup>3</sup> *Surg. Gynec. Obstet.*, 1946, 82, 1.

penicillin failed against Gram-negative bacilli and streptomycin against streptococci, but "sulfamylon" inhibited all species of organisms tested. The upshot of all these tests, together with some clinical trials, was to place "sulfamylon" first in order of merit, streptomycin second, and penicillin third, with a recommendation that the first two be used in combination.

Tyrothricin is the subject of an extensive clinical study by D. D. Kozoll and others,<sup>4</sup> who illustrate the effects of applying it as a wet dressing to septic wounds: some of these were conveniently bilateral, one side being treated and the other used as a control. The results in coccal infections were good; the growth of diphtheroids and *Ps. pyocyanea* appeared to be "encouraged." E. A. Brown and his colleagues<sup>5</sup> introduce a solution of carbamide peroxide in glycerine, which they propose to call "thenardol" after L. Thénard, the discoverer of hydrogen peroxide, as an antiseptic for various types of local infection. The main evidence presented in this paper comprises tests by the gar cup technique, a proceeding which does not in itself carry conviction even of potential *in vivo* activity, but favourable clinical results are also briefly mentioned.

### POLLEN ALLERGY

Reports of air-borne allergens causing dermatitis have appeared from time to time since 1918.<sup>6</sup> Such allergens may give rise to a contact dermatitis or, if inhaled, to an atopic dermatitis. Pollens are especially suitable for investigation as possible causes, since they are potent allergens and the times of their seasonal occurrences are known. Rowe in 1937<sup>7</sup> presented statistical data on 30 cases of allergic (atopic) dermatitis in which inhalant allergy was the chief or only cause, pollens being the dominant influence in 27. More recently Rowe<sup>8</sup> has described for the first time 6 cases of atopic dermatitis (eczema) of the hands as the sole or major manifestation of inhalant pollen allergy. He found 16 such cases out of 180 of atopic dermatitis of the hands that he has studied during the last eight years. The rash usually occurs on the backs of the hands and on the backs and sides of the fingers, less often on the palms and round the wrists. It is usually bilateral and fairly symmetrical. Often after the dermatitis of the hands has recurred for several years other areas of the skin—the face, the neck, the extremities, and very occasionally the body—may become involved. Rowe points out that, as in all cases of clinical allergy, the only evidence of sensitivity may be that obtained from the history, the onset or aggravation of the rash during the pollen season being especially suggestive. The skin tests may or may not be positive: treatment confirms or disproves the diagnosis. Other causes such as other inhalants, drugs, and foods must be excluded, as must the so-called "id" reactions and especially contact dermatitis.

The treatment is perennial desensitization with minute doses of all the pollens encountered during the months when the dermatitis persists, usually using 20 to 50 types. Since the skin tests do not indicate which pollens are the cause of the eczema, all the possible causative pollens are included in the desensitizing solution in order to be certain of including the offending ones. The initial dose is 0.1 ml. of an extract varying in dilution from 1:5,000,000 to 1:5,000,000,000. Injections are given every one to three days. An increase of the itching and dermatitis usually indicates an excessive dose, while with proper dosage there

is a decrease of the rash and the itching in two to three weeks. When there is a distinct improvement the dose can be gradually increased, especially after the pollen in the air has decreased. The dermatitis of the hands in the 6 cases recorded had existed from 3 to 18 years, with an average of 9.3 years. Satisfactory results were obtained in all 6 cases. Rowe appears not to have used inhalation to test any of his patients, and we wonder whether this might not have given a clearer indication of sensitivity than the skin tests. However, his studies are of considerable interest in this most difficult field, and his previous contributions to clinical allergy are such that his views merit the most careful consideration.

### SUNFLOWER-SEED PROTEIN

The sunflower, though grown in this country mainly for decorative purposes, is in many parts of the world a valuable source of food. The seeds are rich in oil, which is edible and readily extracted. The residual meal contains up to 50% of proteins, and should therefore be a valuable food for livestock if its constituent amino-acids are such as to endow it with a high biological value. Doubts on this point were recently expressed by Day and Levin,<sup>1</sup> who concluded that sunflower meal is more important as a source of the vitamin B complex than of protein. In support of this view the biological value of the protein was found by Mitchell, Hamilton, and Beadles<sup>2</sup> to be inferior to that of the soya bean, and in the same low class as that of oats, wheat, and barley. Block and Bolling,<sup>3</sup> however, agreed with Grau and Almquist<sup>4</sup> in claiming that the amino-acid analysis of the meal compares very favourably with that of beef muscle. Which of these conflicting views was to be believed? Experiments to clear up this point have now been reported by Grau and Almquist.<sup>5</sup> In this work the growth rates of chicks given South American sunflower meal as a source of protein were compared with the rates of others given casein or sardine meal. As a result the sunflower meal was found to be fully equal to these excellent sources of protein. Its biological value, moreover, was not improved by adding lysine—an amino-acid which is deficient in many cereal and oil-seed proteins. When given at a level equivalent to 20% of protein in the diet the sunflower meal was satisfactory as a complete source of amino-acids for the young chick.

If these results are duly confirmed the sunflower must rank high in nutritive value, particularly among vegetable foodstuffs. In a practical way its excellence has already been recognized in Soviet Russia and other parts of the world, where it is grown in large quantities. In our own country, however, its value as a possible alternative to more familiar crops must obviously depend not only on the food value per unit weight of seed but on numerous other factors, including the yield of seed per acre. Whether sunflowers deserve more attention than that already given by the backyard poultry-keeper, and could profitably take the place of other crops in well-tilled soil, is a question which only the expert agriculturist can decide. A plant which yields both oil and good quality protein, and which does not require tropical warmth or moisture for its cultivation, is, however, certainly worth intensive investigation. The plant-breeder should inquire into the possibility of evolving improved strains with larger seeds and higher oil content. The colonial administrator should not neglect the possibilities of the sunflower when faced with unpromising soil which is unsuitable for other crops.

## THE FOUNDLING HOSPITAL CHILD WELFARE SCHEME

BY

D. H. GEFFEN, M.D., D.P.H.

M.O.H., Metropolitan Borough of St. Pancras

In the early part of the 18th century a certain Capt. Thomas Coram travelled the seas in the Merchant Navy, and during his voyages he was so shocked at the sight of the deplorable conditions under which children were living that he determined when he retired to do something to better their lot in his own country. In 1739 he found the means to achieve his purpose and in 1741 he rented a house in Hatton Gardens for destitute children. In 1745 he completed the building of the Foundling Hospital in Brunswick Square. Hogarth was one of the earliest governors and Handel was also a benefactor. Many will remember this building, which was pulled down within the last few years. It had charm of design and was one of the remaining features of early 18th century London. It was not, however, entirely suitable for the care of children. In 1926 the governors sold the site and buildings and moved temporarily to Redhill, later finding their permanent home at Berkhamsted.

Much controversy ensued on the future of the Brunswick Square site, and at one time it appeared as though St. Pancras would lose this open space, which would be utilized for building purposes. It was largely due to the efforts of Mrs. G. M. Trevelyan that nine acres of the area were made available as playing fields, and the governors were able to repurchase 100,000 sq. ft., to be known as Coram's Gardens, which they determined to use for the benefit of young children. They erected a residential nursery and a day nursery (see Fig.) for

children of the neighbourhood as a memorial to Capt. Coram on the site where he built the original Foundling Hospital, and together with these a model nursery school for some 80 children with a series of large rooms for the instruction of pupils in the care of babies and children. All the arrangements for the residential and day nurseries and the nursery school are ideal, providing ample playing space, a southern aspect, hygienic walls and floors, the most modern toilet arrangements particularly suited to young children, and window space of ideal proportions in a building of beautiful design.

When all these preparations were completed the war broke out in 1939, and it was decided that London was unsuitable for keeping a large number of children together in an area likely to be attacked by enemy action. The premises were requisitioned by the St. Pancras Borough Council and used as a rest centre, in which capacity they were of inestimable value. A year or two later, however, the need for day nurseries in London became of paramount importance to enable women to work. By arrangement with the governors the ground floor of the residential nursery was utilized by the St. Pancras Borough Council as a wartime day nursery, and the governors made available to the Council their furniture and equipment. At the end of the war it was possible to derequisition that part of the premises used as a rest centre, and in due course the nursery school block was opened and is now administered by the St. Leonard's Nursery School Committee with the help and support of the governors.

The next development was the need to find residential accommodation for babies, and by arrangement with the St. Pancras Borough Council the first floor of the day nursery has been made available for this purpose. A scheme has been agreed between the governors of the Foundling Hospital and the St. Pancras Borough Council whereby there shall be one matron, one doctor, and one kitchen staff for both the day and the residential nurseries, but the nursing staff will be separate. It

is hoped that within a matter of weeks the residential nursery will be open and receiving its first young residents. There will then be on the site a day nursery, a residential nursery, a nursery school, and teaching quarters ideal in design and efficiency.

### Teaching Centre

It became obvious that here was not only an opportunity for caring for young children by the many means now considered appropriate, but an excellent opportunity for teaching, for over the road is the Great Ormond Street Hospital for Sick Children with the Nuffield Institute of Child Health, and nearby is the London School of Hygiene and Tropical Medicine, both bodies keenly interested in teaching child welfare to doctors from both Britain and the Empire. The friendly help of Col. Nichols, secretary of the Foundling Hospital, made it easy for Prof. Alan Moncrieff, as Director, and for me, as lecturer on Public Health at the Institute of Child Health, to place a plan before the governors to complete their scheme for the care of children.

We suggested that the war-damaged building originally used as a canteen and later as a laundry should be repaired and converted to form a maternity and child welfare centre, with ultimate provision for a minor ailment clinic for school-children. A tentative ground plan was prepared by the architect. At this stage the governors are prepared to carry out the work to convert this derelict building into a maternity and child welfare centre provided the local authority will be responsible for its maintenance, staffing, and upkeep.

The governors of the Foundling Hospital placed this proposition before the St. Pancras Borough Council, and it received their immediate and whole-hearted support. The scheme links the governors' welfare work on the Foundling site with local authority activities and co-ordinates it with the Institute of Child Health at Great Ormond Street Hospital. It is anticipated that the staffing of the welfare clinic, and possibly even of the residential nursery, may in due course be carried out in conjunction with that hospital. In addition, this site would provide a training ground for postgraduate teaching at the Institute of Child Health for doctors studying for the Diploma in Child Health and for nurses as well. Co-operation already exists between the Institute and the St. Pancras Borough Council, for the medical officer of health of St. Pancras is lecturer at the Institute, the assistant medical officers of the Council are external tutors, and there is interchange of staff between the Institute and the Council's welfare medical officers—a scheme suggested in the report of the British Paediatric Association. This proposal to build a welfare centre will be placed before the Ministry of Health for approval and will be considered by them in conjunction with the L.C.C., which is the new health authority and will be responsible for child welfare in the near future.

Associated with the child welfare activities of the governors on this site there exist the residential schools at Berkhamsted and homes which they are administering for the care of women and children. Furthermore, a large area adjoining the site has been scheduled for the erection of one of the L.C.C.'s new schools, and the St. Pancras Borough Council has acquired many acres on which it has already begun to build blocks of modern flats. If this scheme is adopted there will be on this site and in the vicinity modern flats, a modern school, a nursery school, a residential nursery, a day nursery, a maternity and child welfare centre, a school clinic (possibly with a dental clinic), a swimming pool, nine acres of playing fields, and perhaps one of the clinics envisaged in the new Act for general practitioners—and this in the heart of London and in the centre of London's teaching district. It will indeed be a centre of health and health teaching, and an example of the finest type of co-operation between the Government, local authorities, teaching bodies, and voluntary associations.

The Board of Registration of Medical Auxiliaries has recently published the seventh edition of its *National Register of Medical Auxiliary Services*, which gives the names and addresses of persons engaged in work ancillary to medical science and practice. Medical practitioners may obtain a copy free from the Registrar, Board of Registration of Medical Auxiliaries, Tavistock House North, Tavistock Square, London, W.C.1.

## BARTHOLOMEW MOSSE

## FOUNDER OF THE ROTUNDA HOSPITAL

Next week the Rotunda Hospital is celebrating its bicentenary. An International Congress of Obstetricians and Gynaecologists will discuss such subjects as puerperal sepsis, eclampsia, and obstetric shock. There will be receptions, dinners, and sherry parties. Ireland always does these things well, and Dublin outstandingly so. According to Oliver St. John Gogarty, Dublin is "a state of mind," but it is a state of mind best appreciated within easy reach of O'Connell Street.

In the course of the celebrations, which the war prevented being held in 1945, the Congress will hear addresses by Mahfouz Pasha, from Egypt; Prof. Bernhard Zondek, from the Hadassah Hospital in Jerusalem; and many distinguished guests from the U.S.A., France, Belgium, Scandinavia, India, South Africa, Australia, Canada, and Great Britain. These and other notable visitors will in their turn be sure to hear some mention of Bartholomew Mosse. They will see his bust in the front hall of the Rotunda Hospital and the portrait which hangs in the board room. There is also an engraving, here reproduced, which he signed and which is in the possession of the Royal College of Physicians of Ireland.

Curran (1945) says that "Dr. Mosse was a man of quite unusual initiative," and that he showed "a magnificent recklessness . . . in the way he risked his reputation and personal fortune in his philanthropic venture." O'Donel Browne (1947), whose recent book is reviewed elsewhere in this issue (p. 17), pays tribute to "his dauntless courage and clear vision." Kirkpatrick in his book, and more recently (1945), has described how Mosse "boldly embarked on his great design." These three authors have told, from different points of view, the history of the Rotunda Hospital.

For the first full account of its remarkable founder it is necessary to go back to an unsigned article published in the *Dublin Quarterly Journal of Medical Science* at the time of the hospital's centenary. Its opening sentences could not, and should not, be paraphrased.

"Men will labour diligently for their own advancement, either directly or indirectly, and will even contribute liberally to the relief of distress; but how seldom do we see an individual devoting his time, his talents, bodily and mental labour, and his wealth, to the sole purpose of raising up an asylum for the relief of suffering, and, at the same time, for the improvement of his own profession, without the prospect—nay, we may say, without the possibility—of an adequate reward? And yet this was what was done, simply and without display, and, as will appear by the following memoir, under circumstances of unparalleled difficulty, by the founder and builder of the Lying-in Hospital in this city."

## Early Days

The Rev. Thomas Mosse, rector of Maryborough, Queen's County, gave his son, Bartholomew, who was born in 1712, a "genteel education." The young man was then apprenticed to John Stone, a Dublin surgeon. By the time he was 21 Bartholomew Mosse was said by the Surgeon-General to be "very well qualified to practise the art of surgery." For a while he had medical charge of men "drafted from Ireland to complete the regiments in Minorca," and later he studied midwifery in England, France, and Holland. Returning to Dublin,

he was admitted a licentiate in midwifery of the King's and Queen's College of Physicians on May 22, 1742. A year later he married his first cousin, Jane, a daughter of the Venerable Charles Whittingham, Archdeacon of Dublin. His first wife had died childless in 1734.

"In the course of his practice charity often demanded his assistance; and he hath often declared, that the misery of the poor women of the city of Dublin, at the time of their lying-in, would scarcely be conceived by any one who had not been an eye witness of their wretched circumstances; that their lodgings were generally in cold garrets open to every wind, or in damp cellars, subject to floods from excessive rains; destitute of attendance, medicines, and often of proper food, by which hundreds perished with their little infants.

"These distresses excited his compassion, and he resolved no longer to delay his endeavours to establish an hospital for poor lying-in women. Having communicated this humane and charitable

intention to a few particular friends who highly approved of his scheme, he took a large house in George Lane, which he furnished with bed and other necessaries, and opened the same on the 15th of March 1745, continuing to support it chiefly at his own expense, and constantly attending it in person until the apparent usefulness of it induced several well-disposed persons to encourage the undertaking by benefactions and yearly subscriptions, which encouraged him to enlarge his plan."

It was obvious that any enlargement would cost a great deal of money. Mosse proceeded to raise the money by "plays, lottery schemes, concerts, oratorios, etc.; and we may mention that he brought over Castrucci, the last pupil of Corelli, as an attraction to these concerts." It should perhaps also be mentioned that the first play arranged by Mosse for the benefit of the Lying-in Hospital was *The Conscious Lovers*. By August, 1748, he had a lease of £70 a year of the present site and a plan for a new hospital. The original Dublin Lying-in Hospital for Poor Women in the twelve and a half years of its existence had dealt with 3,971 deliveries at a total cost of

£3,913 13s. The maternal death rate was slightly more than 1%, the stillbirth rate 1 in 34, and the neonatal death rate 1 in 17. On the new site "he first, at the risk of his whole fortune, laid out and furnished a garden, with an orchestra coffee-room, and decorations, for the entertainment of the public in the manner of Vauxhall, near London, whereon he expended about £2,000. He then employed a band of music and soon found his expectations fulfilled by a constant resort of company during the summer season which produced nearly £400 annually."

## The New Hospital

The foundation-stone of the new hospital was laid by the Lord Mayor of Dublin on June 4, 1751. At this time, in his own words, Mosse was "barely worth £500" and well aware that the hospital would cost £20,000. So he promoted a lottery and sold many tickets, but "the Lords Justices would not allow the drawing." He went to London with a similar project in mind, and "his enemies raised many scandalous and fresh reports giving out that he had absconded for debt and could never return." Another lottery caused further difficulties and ended in his arrest at Holyhead. Nothing daunted, Mosse escaped through a window, persuaded two boatmen to take him some distance away, and "remained in a poor cabin of the wild mountains of Wales for some weeks before he would venture home."

Bartholomew Mosse

Despite these and other difficulties the building of the new hospital proceeded. Though not completed, it was opened on Dec. 8, 1757, and immediately admitted "fifty-two poor women, great with child, who attended in the hall with proper certificates for admission, and were all decently clothed in uniform at the expense of the hospital, each in a blue calimanco gown and petticoat, shift, handkerchief, cap, and apron." The Round Room, whose name has gradually passed to the hospital itself, had yet to be built, but Mosse was a sick man.

"Having greatly impaired his health by intense study and application of mind, by his close attention to the business of the hospital, by constantly superintending the building, and by several fatiguing journeys to London, to forward his schemes, he did not long enjoy the pleasure arising from the success of his labours, for he grew so ill in the beginning of the winter of 1758, that he was obliged for the most part to confine himself to his chamber. Several physicians attended him, but, finding all their endeavours ineffectual, they advised him to return into the country. On this occasion Alderman Peter Barre made him the kind offer of his house at Cullenswood (about a mile from town), which the Doctor readily accepted; and there, on the 16th of February following, he departed this life in the 47th year of his age, and was interred at Donnybrook, leaving the new hospital a monument to posterity of his surprising perseverance, diligence, and ingenuity, and indeed one of the most superb architectural ornaments of the great and elegant city of Dublin."

Bartholomew Mosse was followed as Master by Fielding Ould. In a brief lifetime he succeeded in accomplishing what he set out to accomplish.

We are indebted to the Royal College of Physicians of Ireland for permission to reproduce the engraving of Bartholomew Mosse

## SEPTCENTENARY OF BETHLEM

Bethlem mental hospital, which was discussed in these columns last week (June 28, p. 935), celebrated the 700th anniversary of its foundation on June 28. A commemoration service was held in the Lady Wakefield Chapel, conducted by the Bishop of Croydon and attended by the Lord Mayor of London as senior governor. The association of Bethlem with the City of London was further emphasized at a luncheon when the principal speech was made by Mr. Ralph Ashteton, Member of Parliament for the City, who, recalling the fact that Bethlem began its existence in the reign of Henry III as a monastery, said that formerly the physician of the soul and the physician of the body were often one and the same person, and suggested that the separation of these functions which modern science had brought about was in many respects unfortunate. Sir Arthur Rucker, deputy secretary of the Ministry of Health, responded for the guests. Later in the afternoon a garden party in the grounds of the hospital was attended by H.M. Queen Mary, who planted a tree to mark the occasion. Demonstrations were given in the occupational therapy department and in the Lord Wakefield treatment and research unit. The visitors included many psychiatrists from various parts of the country.

## CLINICAL TRIALS OF STREPTOMYCIN

Doctors in southern England, including the London area, wishing to propose cases of acute military tuberculosis or tuberculous meningitis for admission to a Medical Research Council trials centre for streptomycin treatment should, from July 4, make their request through the Emergency Bed Service, London (Monarch 8515: day and night service). The Service will be kept fully informed of the number and type of cases which can be admitted to each centre, and where a bed is available will direct the inquiry to the appropriate medical officer. It should be emphasized that the number of cases which it will be possible to admit for treatment during the period of the present tests is still limited. Trials of streptomycin in tuberculous meningitis in children aged up to 8 are also being made, under the Council's authority, at the Alder Hey Children's Hospital, Liverpool, and the Royal Hospital for Sick Children, Glasgow, as was indicated in a recent annotation (June 7, p. 814).

## DR. ANGELUS

## A NEW PLAY BY JAMES BRIDIE

The work of a medical playwright always holds a special interest for his colleagues. James Bridie's new play, *Dr. Angelus*, was given its first performance in Edinburgh last week. Ranging over the medical curriculum, Bridie has shown us the romance of the dissecting-room in *The Anatomist* and, while the clergyman slept, has drawn in heroic lines the drama of the laboratory and tilted at some theories of eugenics. *Dr. Angelus* takes us through the medium of the far-from-chromium-plated consulting-room of a Glasgow general practitioner (of Edinburgh training) into the realms of psychopathology. This eccentric gentleman successfully murders his mother-in-law and his wife on the entirely logical grounds that women of their mediocre intellectual and other qualities are a handicap to the full development of his capacities and are at the same time insured for useful sums of money. This he accomplishes by the simple expedient of persuading them that they are ill and "treating" them with spectacular doses of antimony. As part of the "build-up" designed to prevent any unenlightened interference with his plan he takes into partnership an earnest and simple-minded young Englishman, a product of Durham University and St. Thomas's Hospital, and cajoles him into signing the death certificates. As a further precaution he calls in, at a last-minute consultation, Sir Gregory Butt, whom he endeavours to deceive with details of careful clinical investigation and an appearance of affectionate solicitude, albeit perfunctorily and contemptuously, since he shrewdly guesses that worldly considerations will ensure that Sir Gregory will take none but evasive action in the face of a very fishy and unsavoury business. In the end his schemes suffer the frequent fate of those of mice and other men. Fate steps in, taking the shape of the Glasgow C.I.D. and a lady patient, who conceives a dislike for Dr. Angelus and an affection for the young doctor, largely because he recites the Hippocratic Oath to her at the psychological moment. Mrs. Corcoran, the patient, happens most inconveniently to be the wife of an insurance agent.

These contrivances provide full scope for the familiar pawky satire. The poor young Sassenach, Dr. Johnson, barely misses an abrupt and early termination to his career by innocently telling Sir Gregory Butt that his experience in Glasgow has not impressed him with "provincial medicine." The pompous, sanctimonious humbug that is the outward sign of the Angelus megalomania provides a whole rack of pegs on which to hang verbose latinity. The mother-in-law is not "dying" but "hovering on the brink of dissolution." The acting of every one of the small cast of eight is of a high order. Mr. Alistair Sim, one fancies, may well have been in the author's mind when he wrote the play. The appearance, gestures, and diction which gave such a fascinating twist to the parts of the detective in the film *Green for Danger* and the author in *Hue and Cry* are turned to good account in portraying the unctuous insincerity of Dr. Angelus. The one really dramatic incident in the play occurs almost at its end when Angelus is trapped and arrested, and Mr. Sim rose to it magnificently. The dawning realization by the maniac that the whole concept of a super-intelligence mastering Fate was but an illusion, finally shattered by a pair of handcuffs, is brilliantly acted. It reflects in no way on the other members of the cast to mention the admirable performance of Mr. George Cole as young Dr. Johnson and that of Mr. Archie Duncan in the smaller part of the police inspector, more representative perhaps of Scotland than of Scotland Yard.

The play, which is first-class entertainment, is described in the programme as a "psychological thriller." How the author regards it is not easy to guess from his whimsical reference to it in a first-night speech as "this wholesome little play." One suspects parody. However that may be, its main appeal is cerebral and not thalamic, and those who go expecting flesh-creeping thrills will be disappointed. The doctor who sees it will appreciate the professional touch in the clever and subtle picture of a psychopathic type and the not too unkindly tilts at the foibles he often notes in his colleagues.

## Nova et Vetera

### PAEDIATRICS FOUR HUNDRED YEARS AGO

Those who have followed the latest development and plans in paediatrics and child health may find it enlightening to study a work on children's diseases first published in 1545. It is *The Regiment of life, whereunto is added a treatise of the pestilence, with the Booke of children*, by Thomas Phaïre. Like Shakespeare's, the name has several variations. Sir Frederic Still in his *History of Paediatrics* gives the following: Phaer, Phayer, Phayre, etc. The volume from which these extracts are taken is a later edition which is in the medical library of Bristol University. It is stated on the title page to be, "newly corrected and enlarged," and was "Imprinted at London, by Ihon Kyngston and Henry Sutton, dwelling in Paules Church-yard. Anno Domini 1553." It is the first work on paediatrics written by an Englishman, and one of the first medical books to be published in English. The author finds it necessary to apologize for not using Latin:

"But my purpose is here to doo them good that have most nede, that is to saye children: and to shewe the remedies that God hath created for the use of man, to distribute in englyshe to them that are unlearned parte of the treasure that is in other languages, to provoke the [them] that are of better learning, to utter their knowledge in suche lyke attempts: fynally to declare that to the use of many, whyche oughte not to be secrete for luere of a fewe.

I intend in this boke . . . to treat only of the thyngs necessary, as to remove the sicknesses, wherewith the tender babes are oftentimes afflicted, and desolate of remedye, for so much as many do suppose that there is no cure to be ministred unto the by reason of their weakenes. And by yr [their] wayne opinion, yea rather by a foolish feare, they forsake many that myght be well recovered, as it shall appere by the grace of God hereafter in this lytl treatyse, when we come to the declaration of the medicines."

Phaïre strongly advocates breast-feeding, not only on his own account but also as a part of traditional wisdom.

"The Poet Virgyl . . . being thoroughly expert in the priities of nature understode right wel how great an alteracion everything taketh of the humoure by whiche it hath his alymente and nourishing in the youthe: whiche thing also was considred and alleged of many wyse Philosophers: Plato, Theophrastus, Xenophon, Aristotle, d Plinie, who did al ascribe unto the nourement as muche effect more, as to the generacion. . . .

Wherefore as it is agreing to nature, so is it also necessary and comly for the own mother to noure the owne child. Whiche if it maye be done, it shall be moste commendable and hoisome, if not ye must be well advised in takyng of a nouree, not of ill complexion and of worse maners: but suche as shalbe sobre, honeste and chaste, well fourmed, amiable and chearefull, so that she may accustom the infant unto mirth, no dronkarde, vicious nor stutyshe, for suche corrupteth the nature of the chylde."

His "Remedies appropriate to the encreasing of milke in the brestes" are very much like the formulae of some of the modern proprietary lactagogues:

"Parsneppe rotes, and fenelle rotes, sodden in broth of chickens, & afterwarde eaten with a little fresh butter." Or, "The powder of earth wormes dried and dronken in the brothe of a neates tongue." "These thynges have propertie to augment the milke, dylle, anyse scede, fenelle, cristall, hore-hounde, fresh chese, hony, lettuse, beetes, myntes, earette rotes, parsnepes, the dugges or udder of a cowe or a shepe, goates milke, blaunched almondes, ryce porrage, a coves iounge dried and made in powder, potched egges, saffrō, and the iuice of roasted ycale dronken."

The list of diseases mentioned is fairly comprehensive:

Apostumes of the brayne, Swellyng of the head, Scalles of the head, Watchyng out of measure, Terrible dreames and feare in the slepe, the falling cvyll called in the greke tonge epilepsy, the Palsey or shakyn of members, the Crampe or spasmus, Styfnesse of limmes, Bloud-shotten eyes, Wateryng eyes, Seabbynesse and ytehe, Disease in the eares, Neasing out of measure, Bredyng of teeth, Canker in the mouth, Quinsie, or swellynge of the throte, Coughes, Streytynesse of wynde, Feblenesse of the stomake and vomityng, Yeaxyn or hicket, Colyke and rumbling in the guttes, Fluxe of the belly, Stoppyng of the belly, Wormes, Swellyng of the navill, the Stone, Pyssyng in bedde, Brustyng, Fallyng of the fundament, Chafyng of the skynne, Smal poekes and measilles, Feuers, Swellyng of the coddess, Sacer ignis or ehingles, Burnyng and scaldyng, Kybbes, Consumption, Leanenesse, Gogle eyes.

Many of his descriptions reveal a keen observation, for instance:

"Of Wormes. There be divers kinds of wormes in the belly, as long, short, round, flat, and some small as lice. . . . In the long & roūd the paciēt commonly hath a drie cough, paine in the belly and about ye guttes, somtyme yeaxyn [hicough], and trembling in ye nighte, & starte sodainly and fal aslepe agayne, other whyles they gnasshe and grynd their teeth together, the eies waxe hollowe with an eygre loke, & have great delyte in slombing and silence, very loth when they are awaked. . . . Many have but small desyre to meate, and when they desyre they cate very gredelye . . . the hole body cōsumeth and waxeth leane the face pale or blew: somtyme a fluxe, sometimes vomite and in some the bellye is swollen as stiffe as a taberet.

The long and brode wormes are known by the signs that is to say yellownesse or whitishnesse of the eyes, intollerable hunger, great gnawynge and grypyng in the belly, specially afore meate, water coming out at the mouth, or at the fundament, continuall ytehe and rubbing at the nosethrilles, sonken eies and a stinkyng breath, also when the person doth his easement there appeareth in the donge litle flat substances muche like the seedes of eucumers or gourdes.

The other lesser sorte are engendred in the great gutte and may well be known by the excedyng ytehe in the fundament within, and are oftentimes sene comyng out with the excrementes: they be called of phisicians ascarides."

The treatments recommended are scolitabotanē or herbe coralline, gall of a bull, colocinth, aloes, and wormesede.

Again, of Chafynge of the skynne: "In the flankes, arme-holes and under the eares, it chaunceeth oftentimes that the skynne fretteth either by the chyldes owne uryne or for the defaute of wasshyng or els by wrapping and keping to hote." Of "Watching out of measure," or sleeplessness. Phaïre says:

"Slepe is the nouryshment and fooode of a sucking child, and as much requisite as ye very tente, wherefore whā it is deprived of the naturall rest, all the hole body falleth in distēper: erudite and weakenes, it proceedeth commonly by corrupeion of the mylke, or to muche abundance, whiche overladeth the stomake, and for lacke of good dygestion, vapours and fumes aryse into the head, and infect the brayne, by reason wherof the child can not slepe, but turneth and vexeth it self w crying."

The treatment which he recommends would not find favour nowadays: "If you can gette any syrupe of, popye, geue it to the chylde to licke . . . also an oymnt made of seede of popy and the heades." Of Terrible dreames and feare in the slepe:

"Oftentimes it happeneth that the chylde is afraid in ye slepe, & somtymes waketh sodainly, & sterteth, somtymes shrieketh and trembleth, whiche effect cometh of the arysing of stynkyng vapours out of ye stomake into the fantasie, and senes of the brayne." The prevention of this: "take hede that the chylde sleepe not with a full stomake, but to beare it about wakyng, tyl part bee dygested and whan that it is layde, not to rocke it muche for overmuch shaking letteth digestion and maketh the childe many tymes to vomite."

Other treatments are, for Brustyng (i.e., hernia), caused by "greate cryng and stoppyng of the breath, byndyng to straighte, or by a fall or of to greate rockyng and such like . . . the guttes fall downe into the eod, which if it be no utterly incurable, may be healed after this forte. First lai the paciēt so upon hys baeke, that his heade maye be lowe than his heeles, than take and reduce the bowles with your hande into the due place, afterwarde ye shall make a plaiste to be layde upon the eoddes, & bounde with a lace round about the baeke."

Fallyng of the fundament: "The gut called of the latine: reetum intestinum, falleth out at the foundament, and can no be gotten in agayne without peine and labour . . . let the child sit in a hote bath made of the decoction of mallowes holyhocke, lyneseede, and the rootes of lilyes, wherein y shall bathe the foundament with a softe eloute or a sponge and whan the place is suppld thruste it in agayne."

Finally, for Smal poekes and Measilles, Phaïre gives advice which can scarcely be bettered even now: "The best and most sure helpe in this ease is not to meddle with anye kynde o medicines, but to let nature work her operacion."

## Preparations and Appliances

### SAFETY APPARATUS FOR ADMINISTERING TRILENE-AND-AIR ANALGESIA

DRS. A. L. HYATT, T. H. GARDENER, and JOHN ELAM write: Purified trichlorethylene ("trilene"), which has proved a satisfactory anaesthetic agent in general surgery, has a special value in obstetrics for obtaining both anaesthesia and analgesia. Trilene, in therapeutic doses, is pleasant to inhale, causes little or no nausea or vomiting, does not interfere with the normal contractions of the uterus, and, so far as our experience goes, does not appear to have any harmful effect on mother or baby. Its chemical formula is somewhat akin to that of chloroform, and it is possible that "delayed chloroform poisoning" may occur after the administration of trilene, though no cases have yet been reported. Cardiac irregularities have been noticed with some frequency under full trilene anaesthesia, but not when trilene is administered to obtain analgesia in obstetrics.

Given a safe apparatus, it appears that trilene analgesia can be safely administered by the midwife. Dr. Hyatt, of Barnet, has designed such a machine, which is produced by Messrs. Seibe Gorman and Co., Davis Road, Tolworth, Surrey, and which is described below.

*Description of Apparatus.*—Trilene is poured through the filter-cap, A, while the apparatus is held in an inverted position. Air is inspired through four air-holes, B, passes down through an outer tube, C, and then over the surface of the trilene and up another tube inside the tube C, thence to the rubber tubing and facepiece. D shows a spring ratchet; E is an expiratory valve; F shows variable air adjustment and G a locking device for extra air. H is a locking device for the bottle; J a key to fit G and H, and L shows an antispill device.

The special advantages associated with the new apparatus are: (1) it cannot be overfilled; (2) liquid trilene cannot reach the patient; (3) the bottle cannot be unscrewed (except by using the key); (4) the midwife could not make the percentage of trilene too strong, as this is prevented by a locking device; (5) the proportion of air over trilene is always a constant factor, owing to the air inlet design, and is not altered by depth of inspiration; (6) the clamp is designed on a spring ratchet and is perfectly stable in any position; (7) a graduated scale of extra air\* is calculated from 0-10 and set to an arrow.

Two of us (T. H. G. and A. L. H.) have administered trilene to 300 patients in their own homes without once failing to obtain adequate analgesia, and without the slightest harm to mother or baby. At Wellhouse Hospital, Barnet, trilene-and-air analgesia has been in use since the autumn of 1941. The number of cases receiving this form of analgesia has been limited by the necessity for training midwives in gas-and-air analgesia. Dr. Canwarden, of St. Luke's Hospital, Guildford, reports, after having two of Dr. Hyatt's machines in use at this hospital: "The patients are most enthusiastic about trilene analgesia, and I have done a matter of a dozen forceps deliveries, with the patient giving her own anaesthetic."

\* This does not mean percentage of trilene to air.

Drs. Greig and Goodheart, of St. Helier Hospital, Carshalton, have kindly carried out an investigation to enable a comparison to be made between the degree of analgesia obtained from trilene and air (from the new machine) and that given from the standard Minnitt apparatus. They consider that the results obtained are not yet convincing from the obstetric angle, as the number of cases was too small. The midwives in charge noted no effect on labour contractions from trilene. Drs. Greig and Goodheart conclude: "We are very pleased, and would always elect to have a trilene machine for convenience of transport, convenience of maintenance, and cheapness; and, of course, the trilene machine scores over anything else of the kind in being capable of different concentration, especially in being capable of concentration to full anaesthesia. We want to do a lot more of these cases rather quickly."

## Reports of Societies

### ACUTE OTITIS MEDIA

At a meeting of the Section of Laryngology and Otology of the Royal Academy of Medicine in Ireland on May 15, the President, Dr. T. G. WILSON, welcomed Mr. GEOFFREY H. BATEMAN, of St. Thomas's Hospital, London, who read a paper on "The Place of Chemotherapy and Penicillin in the Treatment of Acute Otitis Media."

He said that for years he had been sceptical of the claims made for chemotherapy, and cited cases in which mastoid operations were necessary after the otitis media had apparently been cured. He showed statistics to illustrate the difference in the results of those cases treated with the sulphonamides and penicillin and those untreated. In the sulphonamide group the incidence of mastoid operations was higher and the duration of stay in hospital longer, but there was a reduction in the number of cases with dry ears that later developed otorrhoea. He thought that sulphonamide therapy had little effect on the course of otitis media, but would frequently cause an ear to become dry even in the presence of an infected mastoid. It was therefore necessary not to pronounce a cure until the hearing had completely returned, with full lustre of the membrane. He recommended x-ray examination if response to treatment was not satisfactory after three to four days, since this would be invaluable as a control if skiagrams were later required.

Dr. T. O. GRAHAM said he was a strong supporter of the use of sulphonamides and penicillin in the prevention of complications in otitis media. In their hospitals to-day a mastoid operation was rare, due to the fact that the general practitioners were well tutored in the use of penicillin and sulphonamide and gave them adequately and early. Their very low figure of mastoid operations might possibly be due also to the fact that their organisms were less virulent, but he considered it a dangerous thing to preach that sulphonamides and penicillin should not be used in cases of otitis media.

Dr. A. FAGAN said that in his earlier days myringotomy was quite common, but since the advent of the sulphonamides and penicillin that operation had practically disappeared. However, though the advent of sulphonamide had lessened the occurrence of acute otitis media here, it should be borne in mind that this had coincided with the compulsory examination of school-children. Dr. R. R. WOODS said that the incidence of the mastoid operation had always been much higher in England than in Ireland, and suggested this might be due to different bacteria or different types of ears. Since the advent of chemotherapy the incidence of mastoid operations had diminished to about one-fifth of what they previously were. On the whole he did not think the speaker's figures comparable with those in Ireland.

*Health Bulletin*, issued by the Chief Medical Officer of the Department of Health for Scotland, appears for the first time in its 5½ years' existence free of its confidential cover. It records an address on infantile cerebral palsy by Dr. Earl Carlson, of New York, an article on the psychosomatic aspects of chronic sickness by Dr. J. L. Halliday, a lecture on anaemia in infancy and childhood by Dr. G. B. Fleming, as well as an interesting review of influenza in Scotland.

## Correspondence

### General Knowledge and General Practice

SIR,—As one who has been for some time seriously concerned about the matter which Dr. D. N. Baron raises (June 21, p. 902) and has even endeavoured, in a recent book, to provide some small means to help the doctor to fill the important gaps which Dr. Baron mentions, I am glad to see the subject brought out into the open in your columns. For the successful conduct of medical practice in a living society among patients whose lives must be fitted into the social pattern it ought to be abundantly clear that the doctor must know something about the anatomy, the physiology, and the pathology of society, as well as having some conception of the manifold incidentals—the arts, the humanities, and the philosophies—which colour his patients' lives. The possession of such knowledge is one of the characteristics of the good doctor. It often distinguished the "old-fashioned" G.P. from his scientific successor, however much the latter might tend to feel superior to the former, and it may well be one of the reasons why, even nowadays, academic prowess does not always presage success in the daily work of medicine.

It is all to the good that we should wake up to the fact that the medical school, even where it is nominally part of a university, tends to isolate its students from those in other faculties. It is inevitable that those in the later stages of a six-year course should mix little with those taking a three-year course in other subjects, but even in his first preclinical years the medical student's first allegiance is usually given to the hospital in which his future lies rather than to the university or college in which he is spending his present. Where the hospital medical school contains its own preclinical department, so that the student not only loses the need to be associated with a university but is even robbed of contact with students who are doing biology or physiology for a B.Sc. degree, the position is obviously worse.

An important contribution to the present situation has been the custom by which the youngster takes his first M.B. before leaving school. It may be in keeping with the baser materialism of to-day to regard the two years between matriculation at 16 and university entrance at 18 as wasted unless they are used in anticipating the first university year, but it is in those years that the young man or woman could not only learn the beginnings of the arts, the humanities, and economics but could develop that interest in them which would enable him, or her, to make full use of any incidental opportunities which might turn up during the medical student years.

It might be a useful immediate remedy to insist on the last two years at school being spent in real education; most good schoolmasters would co-operate. At the same time there is every reason why throughout the medical curriculum some attention should be given to these ancillary subjects. They are, in the full sense, part of social medicine, and it is encouraging to know that one British university at least is planning to teach a little sociology to both preclinical and clinical medical students. What we must avoid is the pretence that the individual who is interested can learn this sort of thing after he qualifies. He will be too busy at the wrong hours, and there is always some little constraint and restraint which hedges in the doctor. He is separated from his fellows on the human plane by the actual or potential professional relationship which subsists between the doctor and the layman. Most of all, unless he has learnt something of the elementary grammar of humanity before he is 25, he is going to find it hard to read profitably in the book of mankind. Shaw had a phrase for us in *Man and Superman*: "Not educated—only college pass-men." Surely the doctor is the last of all men who should merit such a description.—I am, etc.,

Colchester.

JOHN D. KERSHAW.

SIR,—Is it too much to hope that the advocates of the mass production of medical practitioners—I use the designation deliberately—will ponder the letter of Dr. D. N. Baron (June 21, p. 902)? There must be a considerable number of doctors who feel as Dr. Baron does, and from time to time attention has been drawn in the *British Medical Journal* to the need for a wider general education among the entrants into the profession. I go further than Dr. Baron and maintain that, in the

case of the medical specialist even more than of the general practitioner, the first prerequisite is, in his own words, "the broad cultural background." Perhaps I may be permitted to quote from an unpublished essay which I wrote some five years ago:

"Let us pass to another aspect of the place in human affairs of biology and medicine. With the tendency to reduce all life to equations or formulae, we are apt to move along in one direction and develop one-track minds. In particular I refer to the cult of specialization which is growing. I do not decry specialization in science or medicine because for present-day civilization such specialization fills local or momentary needs; but, if I may be allowed to borrow a military expression, such specialization should be regarded merely as the 'tactics' of life, and more and more attention will need to be paid to the broader 'strategy' of life, towards which we should bring a broader mental equipment."

Medical men have been accused in the past, and still continue to be accused, of narrowness of outlook, of extreme professionalism; it is a charge which it is difficult for us to answer and one which is not wholly unmerited. This is all the more remarkable when medical education and training have been thought to be the most liberal education of all. But it is not only medicine which has to face up to this charge. As Prof. Whitehead once wrote:

"The fixed person for the fixed duties, who in older societies was such a godsend, in the future will be a public danger. In the second place, the modern professionalism in knowledge works in the opposite direction so far as the intellectual sphere is concerned. The modern chemist is likely to be weak in zoology, weaker still in his general knowledge of the Elizabethan drama, and completely ignorant of the principles of rhythm in English versification. It is probably safe to ignore his knowledge of ancient history. Effective knowledge is professionalized knowledge, supported by a restricted acquaintance with useful subjects subservient to it. This situation has its dangers. It produces minds in a groove. Each profession makes progress but it is progress in its own groove."

"The effect of scientific thought during the nineteenth century was to attempt to subject all phenomena to measurement and classification: this has been the result of centuries of the growth and perfection of mathematics, and we passed from mysticism and philosophy to the cult of exactitude."

It is small wonder, therefore, that one of our sanest present-day medical writers, Prof. Major Greenwood, was impelled to write in his *Epidemics and Crowd Diseases*:

"I suppose the man who first exposed an animal to a high pressure of life-giving and life-sustaining oxygen and saw it go into convulsions and die had a shock. Perhaps the great biochemist who a quarter of a century ago showed that animals supplied with all the necessary energy and building stones in the form of chemically pure proteins, fat, and carbohydrate, and the appropriate inorganic material—everything Victorian scientific hearts could desire—did not thrive may have passed through a moment of painful perplexity."

And now what next? We are still at the stage where we are unable to measure or classify all the aspects of existence, and so we are in danger of falling back upon philosophy once more for our explanations, as witness the growth of new and specialized sciences and philosophies. Perhaps we may be reaching a stage of regression or stagnation such as has occurred in the past, and this may even be a good thing to enable us fully to assimilate and use the plethora of "scientific" food set before us and to avoid the obvious danger of scientific indigestion. If I am right in thinking this, the need for a broader based education for us all—doctors and scientists alike—becomes more important.—I am, etc.,

Elton, Notts.

V. L. FERGUSON.

### Care and Treatment of Elderly and Infirm

SIR,—The report of the B.M.A. Committee on the Care and Treatment of the Elderly and Infirm (*Supplement*, June 21 p. 133) is a promising but somewhat utopian document. One or two rather pressing questions remain totally unanswered by it. The first of these—Who is going to organize and run the geriatric departments?—will be hard to answer, since there are as yet only a mere handful of geriatric specialists. A second follows logically: How and where are we going to train our future workers in this field?

At present the average medical and nursing standards in the chronic and senile hospitals are low. Many changes will be necessary to give them either the equipment, the atmosphere or the prestige which should belong to training schools. To

take one practical example: many chronic hospitals have no physiotherapy department, yet physiotherapy is one of the corner-stones in the treatment and rehabilitation of the aged. With such a department, properly run, the famous 40, 40, 20 ratio is not difficult to attain; without it the physician is troubled. This has been my own experience.

Similarly, specialists must be easily accessible. An ortho-aedic surgeon, an ophthalmic surgeon, and a neurologist are essential. I cannot recollect any mention of this vital necessity for team work being stressed in the report. Finally the mechanism for admission and discharge of patients, with arrangements for following them up, will need careful attention. The present municipal hospital practice is far from satisfactory in this respect, so that special machinery must be created with the new long-stay annexes when they are formed. One last word: most of this report is concerned with the 5% of old folk in hospitals or institutions. Will it help the general practitioners who look after the remaining 95%?—I am, etc.,

Purley, Surrey.

TREVOR H. HOWELL.

### Health of Young Workers

SIR.—In the leading article entitled "Whither Industrial Medicine?" (June 14, p. 853) mention is made of the importance of health supervision of juveniles in industry. "In this field alone," you state, "industrial medicine could make a significant contribution to positive health." It may therefore be of interest to note certain recommendations recently made by the Central Advisory Council for Education (England) in the publication *School and Life* (H.M.S.O., 1947). This Advisory Council was appointed by the Minister of Education, under Section 4 of the Education Act, 1944, to advise him "upon such matters connected with educational theory and practice as they think fit." By agreement with the Minister the Advisory Council addressed itself first to the transition from life at school to independent life, and, in this connexion, has proposed measures for supervising health during the early years of employment: medical examination on entry should apply to all boys and girls up to the age of 18, and should lead to treatment, supervision, and guidance for all those found to be unfit; and to give effect to this the duty of making such an examination should be transferred to the school health service, which should also be responsible for treatment and supervision.

In view of the definite challenge to industrial medicine so clearly presented in your leader it would be of value to hear further opinions on the subject from those both interested and personally taking part in health supervision of young persons at school, in the home, and at work.—I am, etc.,

Loughridge, Birmingham.

C. H. HOSKYN.

### Treatment of the Maladjusted Child

SIR.—Even if the statistics of the paper by Drs. Elizabeth G. W. Barker and W. Liddell Milligan (June 7, p. 805) are not good, nevertheless I do not doubt the sincerity of their work and I am sure they are getting results. But two questions arise from their excellent work—namely: (a) Is a mental hospital better than schools or hostels for maladjusted children? (b) Do the children not come into contact through the patients with psychological "mechanisms" and attitudes to life which will cause more serious maladjustment in later life?

The authors did not state what conclusion they drew from the fact that they were receiving requests for admissions from all over England. Three conclusions will be difficult to exclude—namely, (a) ignorance by the source of the most modern methods of treating maladjustment; (b) correct knowledge at the source but in absence of any place, such as schools or hostels, to put them; (c) economy. As things stand at present the Portsmouth people are to be congratulated, but would a villa for the children alone not be much better than the convalescent female villa? It would then be logically difficult to put the convalescent females among the children.

So-called psychosis in children (of normal intelligence) is practically always the result of provocation, overstimulation, or frustration in different directions, but it reacts well to association with trained adults in an environment where provocation and frustration are removed, even in cases with poor heredity. Uneducated grandparents excepted, there can be few people more provocative to children than psychotic females.

In my opinion the best methods of training the maladjusted child (of normal intelligence) are in this order: (a) Out-patient attendance by father, mother, and child at child guidance clinic; (b) removal of father, mother, and children to a hostel (with the father going out to work from the hostel) for short periods, to be repeated in association with attendance at a child guidance clinic for longer periods; (c) removal of child to a residential school for maladjusted children accepted by the Ministry of Education; (d) removal of the child to a hostel (but local authority hostels have a long way to go before they reach the standard of efficiency of staffing, organization, and of material at the disposal of the good mental hospitals); (e) mental hospitals as an expedient or emergency.—I am, etc.,

Westcliff, Essex.

JOHN A. MCCLUSKIE.

### Health of Children Attending Day Nurseries

SIR.—I am certain that Dr. F. Gray's letter (June 21, p. 899) will have inspired many medical women to take up their pens. I had hoped that the time had come when we could be accepted by our male colleagues as useful members of the profession. There are many women who believe they have a useful social function outside the home. Why such women should be denied the pleasure of marriage and children is something I cannot understand. I will not take time to refute Dr. Gray's conclusions, but I consider that those medical men who have worked with women doctors, nurses, pharmacists, etc., will know that they are neither "masculine" nor "irresponsible," and I am disgusted that a responsible journal like the *B.M.J.* has thought fit to publish such a letter.—I am, etc.,

London, N.W.5.

BARBARA SIMONDS.

SIR.—From the business-like description of the masculine woman and her failings one may infer that Dr. F. Gray (June 21, p. 899) is in no position to appreciate the emotional difficulties experienced by one who has been trained for a "man's" job and is condemned by nature and society to reverse all her training and attempt the art of home-building and child-rearing. Certain women cannot help their lack of femininity any more than some men can remedy their lack of typically masculine characteristics. Each can only find out by experience what he or she can do competently, and in doing it make a true contribution to the sum of human happiness. Women are often acutely aware of their incompetence to understand a child's outlook, and they are not necessarily "irresponsible" in making a decision to place the children in the care of others who are willing, or are qualified by the State, to undertake part of the training that as mothers they have not been taught to understand.

If housework were considered by men to be a dignified occupation and child-rearing looked upon as a creative art, then the weaker members of the so-called stronger sex might find themselves eminently qualified to be home-builders, while their more robust wives became wage-earners. A good deal of masculine "ill-health and laziness" would thus be avoided, and the need for day nurseries considerably lessened.

A wife's lack of ability to be a "good mother" is the husband's greater opportunity to be a "good father." Marriage is a complementary status, each partner requiring of the other something necessary to the expression of individuality. If the true spirit of marriage is maintained, a right outlet for the energies of both should be established with no prejudice attaching itself to any job that either partner undertakes, so long as the aim and object of both is to create and maintain a home for their offspring. Zealots of health unfortunately lay themselves open to the error of putting asunder those whom a creative force has joined together, thereby lowering the strength of compassion to a nebulous pity which drains away mankind's capacity to evolve a higher form of life.—I am, etc.,

Newcastle-upon-Tyne.

G. M. LANGHAM-HOBART.

SIR.—The flood of letters abusing the day nurseries that Dr. Margaret E. McLaughlin's paper (May 3 and 10) has unleashed require a close scrutiny. I feel that the majority of them are inspired by a ferocity arising from a political prejudice and that they are much out of line when compared with the

usually well-conceived publications that are so characteristic of the English medical man's sane outlook.

Dr. McLaughlin's careful paper collapses on two most important points:

(a) The control group of children are those who live at home. Now these children come from a better type of home both from the point of view of mother's character and also financial stability, and they are therefore not true controls. Nobody is going to deny that the children living at home under the care of their mothers will be finer and fitter than the poor little soul bundled out of home at 7.30 a.m. come sun, come rain, inadequately washed, and often inadequately fed. But what are we going to do with the illegitimate child of the mother "forced to go to work"? These represent the majority of the children in day nurseries of which I have experience, not the absurd picture of the masculine mother in Dr. F. Gray's letter (June 21, p. 899). The "business executive" does not send her child to the day nursery. The day nursery children are certainly much better looked after in the nursery than allowed to run riot in the streets with the penny bun for lunch, or looked after by an already overworked neighbour.

(b) It is of course agreed that children *en masse* are more prone to infections one from the other. Why not, therefore, agitate against the kindergarten that the middle-class parents use? Obviously because it is unnecessary—unnecessary because those children come from a healthier and wealthier home than their more unfortunate brothers and sisters and can therefore withstand the onslaughts of infectious illness. Yet the day nursery and the kindergarten are strikingly similar. This, to my mind, proves that it is not the day nurseries that are at fault but rather the homes from which the nursery children are drawn.

I come now to my final point. In no papers that I have seen has there been an attempt to stamp out nasopharyngeal infections in the day nursery. Surely a healthy nose and throat will give the child a greater chance of avoiding infectious illnesses. Why not administer a routine nose drop as soon as the ubiquitous mucopurulent stream is seen tracking down the upper lip?

I should like to end with an appeal for a saner and less prejudiced outlook on the question of the children of the mother "forced to go to work." It will become even more urgent in the future as more and more women go into industry.—I am, etc.,

London, W.C.2.

J. Z. GARSON.

### Treatment of Acute Mastitis

SIR,—While agreeing with Dr. J. MacLeod's treatment of acute mastitis (June 14, p. 865) by penicillin intramuscularly, I feel that routine stilboestrol is neither necessary nor desirable. I avoid using stilboestrol unless a milk fistula is present and the mother has stopped breast-feeding. From the figures given below the result is gratifying. The value of breast-feeding cannot be overrated, and we must avoid using any method whereby milk production is likely to be curtailed. The breasts can be adequately emptied by a breast pump.

The prevention of acute mastitis begins before the baby is born. Although the hygiene of the nipple is well known to the profession, it is sadly neglected in certain areas. In the majority of cases the aetiological factor is ascending infection from the nipple through the ductal system by *Staphylococcus aureus*, probably originating in the patient's skin. The use of penicillin cream during lactation is not desirable. It may have detrimental effects upon the baby, producing stomatitis and interfering with sucking. The introduction of penicillin has revolutionized the treatment of acute mastitis. It is no longer necessary to make large radial incisions into the breast to break down loculi to produce one abscess cavity from which pus can freely discharge on to the surface. The complications occurring after this method are haemorrhage, secondary wound infection delaying healing, and milk fistula. Frequent and repeated dressings are, both painful and tiring for the patient. Secondary suture means another operation and anaesthetic.

The principles of treatment of mastitis by penicillin are based on the pathology of the condition. All cases of mastitis and breast abscesses commence either as a diffuse suppurative or segmental mastitis. Penicillin acts by producing a localized suppurative mastitis. Depending on the quantity of pus present, either complete resolution or a chronic pyogenic abscess may occur. Thus, penicillin produces changes of chronicity, and when nature fails in severe cases to absorb the pus it is essential to realize this early and evacuate the abscess. I have used several methods to evacuate

the pus, having localized it in necessary cases by giving penicillin, 100,000 units in 1 ml. saline, twice daily for two to three days.

Penicillin Given I.M. b.d. in All Cases	No. of Cases	Organisms	Average No. of Days for Healing to Occur	Remarks
Incision and open drainage	20	<i>Staph. aureus</i>	16	1 milk fistula, 2 haemorrhage, 1 secondary infection with <i>Bact. coli</i>
Incision, with primary suture of wound, with corrugated rubber drain through it	3	" "	14	Slow healing of incision
Incision, evacuation of pus, instillation of penicillin solution, and primary suture	2	" "	12	1 recurrent abscess
Incision, dependent drainage, and primary suture of wound	3	" "	12	Low grade infection of healthy area
Incision, instillation of penicillin through penicillin tube, and primary suture around tube	3	" "	10	Residual induration
Incision, penicillin tube through dependent area, and primary suture of wound	3	" "	11	Low grade infection in healthy skin
Tenotomy incision and penicillin tube	20	" "	7	Induration
Multiple tenotomy incisions and penicillin tubes	1	" "	7	"
Secondary suture	..	Nil		

As the results of tenotomy incisions and penicillin tubes have been uniformly good in the 21 cases, I trust you will allow me more space to describe the methods. The smallest possible incision is made over the centre of the abscess with either a tenotomy knife or, a narrow Bard Parker scalpel. The pus is gently expressed, and a narrow rubber tube stretched on sinus forceps is introduced into the abscess cavity. No suture is required to hold the tube in position, as the skin contracts tightly on it. Penicillin solution, 2,000 units per ml., is injected down the tube until the abscess cavity is filled. The tube is then spigoted. Penicillin, 100,000 units per ml. in saline, is given i.m. twice daily. The contents of the abscess cavity are aspirated twice daily and replaced by penicillin solution. After two to three days the aspirated fluid is clear and usually sterile. The tube is then removed and a penicillin dressing applied. In the event of the resulting cavity filling up again the contents can be gently expressed through the resulting sinus. Healing is generally complete on the sixth day, leaving a residual thickening in the breast. A good support is all that is now required, and after one to two weeks the thickening will have completely disappeared. If desired, short-wave diathermy will hasten this process.

In the presence of multiple abscesses separate tenotomy incisions and penicillin tubes for each abscess treated as above will give similar results.

I wish to thank Mr. Hugh Reid and Mr. A. C. Brewer for allowing me to carry out this treatment on their patients.—I am, etc.,

Liverpool.

R. MARCUS.

### Treatment of Acute Osteomyelitis in Children

SIR,—It would appear from the letter of Drs. J. Trueta and M. Agerholm (June 21, p. 899) on the treatment of acute osteomyelitis in children by penicillin that they have approached the paper by Messrs. T. Twistington Higgins and Denis Browne and Dr. Martin Bodian (May 31, p. 757) with an air of complete disbelief. Having seen some of the results obtained at the Hospital for Sick Children, Great Ormond Street, and at Oxford, I am convinced of the efficacy of both the methods that are being advocated, but "each in its own place." It would seem to be wiser to take this broader view rather than to read more into the text than is apparent. Many of the remarks of Trueta and Agerholm appear rather out of context, especially those relating to surgery. Only two, or possibly three, of the Great Ormond Street cases warrant classification as "open surgery"; two could properly be described as cases of incision of superficial abscesses in an area in which the Oxford method is hardly applicable—as examples, in fact, of the time-honoured method of "free incision and free drainage" of a pointing abscess.

Aspiration is difficult, but the fact that repeated aspirations were needed does not imply that the method was unsuccessful. Many aspirations were needed in order that the amount of pus

present should constantly be minimal. Is it indeed certain that new pus does not form after drilling of a bone? With regard to dosage of penicillin: That advocated by Great Ormond Street does seem to be unnecessarily low. Presumably this is because the series was begun at a time when there was a dearth of the drug, and the dosage was continued because it was found to be adequate. It is a fact that immediate improvement occurred (i.e., within 24 hours) in the majority of the cases. Penicillin must obviously be given to infants by intermittent injection, and the fewer these are the better, provided that an adequate concentration be obtained and the best possible results, for trauma undoubtedly upsets infants and makes handling of them more difficult as regards feeding, etc.

Mobilization does not really form a large part in the treatment recommended. It is rather a suggestion that complete immobilization is unnecessary, and that simple methods are adequate in the acute stage. Certainly there would be little weight-bearing in the infant age group, and it is probable that the risk of pathological fracture is less than the dangers and difficulties involved in plaster immobilization in infants. With regard to positive blood cultures: this may be rather a false percentage, for no doubt some difficulties were experienced in obtaining some or sufficient blood in all cases. This point is not made clear in the article.

It would seem reasonable to accept, with reservations, the principles both of the Great Ormond Street and the Oxford series. It might be wise to use the Oxford method in older patients with severe infections, while the Great Ormond Street technique seems certainly to be adequate in the less severe cases, and in all infants in whom operations should not be undertaken too lightly, and in whom the difficulties of feeding, hydration, and so on have such an important bearing on the ultimate recovery. A dosage scheme dependent upon body weight would appear to be rational and desirable. Such a scheme has been started by Great Ormond Street in this series, and, though it has not yet attained general acceptance, it would seem to be more reasonable than a mere routine dosage for any patient of any weight and any age.—I am, etc..

London, W.1.

IAN P. TODD.

### Myiasis of Palpebral Conjunctiva

SIR.—I was interested to read Dr. T. E. M. Wardill's letter (May 3, p. 615) regarding myiasis of the palpebral conjunctiva. The following case came to my notice recently and may be of interest.

#### CASE REPORT

A soldier aged 20 reported sick on the evening of May 27 with an inflamed eye of a few hours' duration. He told the medical orderly that he could feel something moving about under the lid, and as the orderly could see something moving on the conjunctival surface he informed me.

On examination an acute conjunctivitis of the affected eye was evident, and on evertng the lids, to my surprise, a number of very tiny maggots were just visible. With characteristic dislike of light they wriggled away into the conjunctival fornices, but eventually half a dozen maggots were removed by wiping the palpebral conjunctiva with cotton-wool. One maggot was examined on the point of a needle, and its form was then clearly discernible. On questioning the man he stated that a fly had buzzed into his eye at 10 o'clock that morning, and the eye had become inflamed in the afternoon.

Following removal of the maggots his eye became more comfortable and the following day was quite normal.

The predominant fly around here is *Musca domestica*, but I am unable to say whether this might be the culprit or not.

I am indebted to Lieut.-Col. D. B. Seymour-Price, R.A.M.C., for permission to publish this case report.—I am, etc.,

P. DRANSFIELD,  
Lieutenant, R.A.M.C.

M.E.L.F.

### Acute Non-specific Diarrhoea and Dysentery

SIR.—I read the article by Dr. G. R. Kershaw on the above subject (May 24, p. 717) with pleasant anticipation, hoping to gain some new light on this difficult subject. I was disappointed to find that he appears to have drawn his conclusions after a few years' clinical observation, controlled by only a few full pathological investigations, and with an incomplete knowledge of the extensive literature already published. I have been investigating these cases at sea, as occasion offered, over the last twenty years. In most epidemics I have plated out the faeces, picked off non-lactose-fermenters, and put them through the appropriate sugar media, and tested their agglutination with

standard dysentery and salmonella antisera. I have never identified any pathogen from these cases.

In my paper in the *Lancet* (1938) reviewing this subject the question of chills, cold drinks, etc., was considered, but, after careful investigation, was not thought to be the whole answer and no pathogen was found. My bacterial results were checked by the late Prof. Eyre, of Guy's Hospital. Drinking water was excluded after a research on the *Bact. coli* content of water in ships' tanks extending over a period of 18 months (Royds Jones 1936). I note that Dr. Kershaw also exonerates water (after two analyses). Knowledge gained during the war when carrying troops in convoy allowed us to go a stage further (Royds Jones 1943) and exclude food, water, and a food handler "carrier." It was due to this last letter that I was asked to meet the Director-General of Hygiene at the War Office, who kindly supplied me with a large quantity of media for an extensive research. Unfortunately owing to the progress of the war our route was changed, and we never again got these large epidemics in which 400 to 600 men were affected in one night, and I have not been able to proceed further. Incidentally, the majority of men affected were those sleeping in mess decks, both in hammocks and on the deck, and not those sleeping on open decks, where chilling would have been greatest, although some patients came from each.

My tentative suggestions at the time were either (1) a virus as the cause, or (2) a saprophyte becoming pathogenic at this temperature, for which there is some experimental evidence—Kligler, I. J. (1936), and Robertson and Weld (1932). I discussed the virus theory with a few first-class virus workers, and they at that time were inclined to discredit the suggestion. However, both American and Canadian workers had published papers suggesting a virus as the cause. Now British authorities are more inclined to favour this theory, as witness several articles published recently and your own annotation (Feb. 1, p. 187) about six months ago. I regret that I cannot give exact references to the recent literature, as I am now at sea.—I am, etc..

Banbury, Oxford.

H. M. ROYDS JONES.

### Primary Malaria in London

SIR.—The article by Drs. C. Blaxland Levick and M. E. MacGregor (May 31, p. 764) on "Primary Malaria in London Children" prompts me to write and bring to your notice a further case of this illness in an adult which I encountered during the week of publication of the original article.

The patient was a woman, aged 36, residing in Kensington and a Foreign Office Civil Servant employed at Eastcote. I saw her at home first on Thursday, May 22, 1947, when she was complaining of nausea with frequent vomiting, frontal headache, and lachrimation, back pain, and sweating. It was her belief that she had some form of "gastric 'flu.'" Her temperature was 101.4° F. (38.5° C.). The following day she was little better, and her temperature had dropped to 99° F. (37.2° C.).

On Saturday, May 24, she was moved to friends in Hampstead who were able to look after her better. She was feeling very much better, apyrexial, and thought she had recovered. Sunday evening, however, she developed a recurrence of her symptoms, which were now very much more definite in character and followed the typical stages of malaria, the temperature rising to 102.4° F. (39.1° C.).

Blood slides which were taken the following day when she was apyrexial proved negative; but those taken next day in the middle of a rigor were kindly examined for me by Dr. H. O. Hughes at the Middlesex Hospital, who reports that the films showed scanty trophozoite ring and amoeboid forms, and gametocytes of *Plasmodium vivax* (benign tertian malaria). She has since been given mepacrine and remained free of symptoms.

Her history is interesting. Apart from travelling to and from her work daily she had not been out of London since last Christmas. She was born in India and resided in Calcutta till 1937, when she came to this country, and never had any form of antimalarial therapy given her at any time. The only illness in the past had been German measles, and 3-day fever when she was a schoolgirl aged 12—that is, 24 years ago, and a most unlikely factor in this illness. Her only contact with malaria

was this March, when a friend staying with her had a relapse in her home.

I hope that this case will help further in stressing the fact that primary malaria can be a factor in diagnosis in this country at the present time, where malarial carriers are more numerous and the *Anopheles maculipennis* known to be present.—I am, etc.,

London, W.11.

DAVID A. FERMONT.

### Congenital Hepatic-duct Malformation

SIR,—The case of congenital hepatic-duct malformation recorded by Dr. Frank Riggall (June 7, p. 824) emphasizes the fact that children born without bile ducts, or with the bile ducts so malformed that they do not communicate with the intestine, survive much longer than one would expect. In Riggall's case the child lived for ten months, and in a large series of these cases reviewed by Stolkind<sup>1</sup> there was one where the child survived for 15 months. The question of operation is worth while considering in cases of atresia, for it may be found that sufficient of the common duct is present to allow of anastomosis to the duodenum. In these cases jaundice is usually present at birth or shortly afterwards, but according to Ladd and Gross<sup>2</sup> 2-3 weeks may elapse before the icteric tinge appears, "whereas the stools are always clay coloured or white from birth." Further, they state that if operation is delayed for 4-6 weeks from the date of birth there is little chance of error in differential diagnosis.

Anastomosis of the duct to the duodenum is carried out over a small piece of tubing—somewhat after the method of Sir James Walton<sup>3</sup>—and silk is used for suturing. Vitamin K and ox bile salts are administered beforehand in the hope of diminishing oozing.

Ladd and Gross emphasize the danger of post-operative disruption of the wound, and advise the use of silk and silkworm gut for stitching the abdominal wall. In 45 of their cases nine patients were found to have a patent hepatic or common bile duct connected with the intrahepatic ductal system but not with the duodenum; 6 out of 9 cases survived the operation and were in excellent health 12, 8, 7, 5, 4, and 3 years respectively after operation.

Dr. Frank Riggall is to be congratulated on taking the trouble of publishing his interesting case in the *British Medical Journal*.—I am, etc.,

London, W.1.

### E.C.T.

SIR,—Your correspondent who explains (June 14, p. 858) his reactions to E.C.T. is to be highly congratulated for the enlightened description of his experience, and his article should do much towards alleviating the acrimony at present being expressed on the subject. His important contribution lies in the cognizance that the treatment produced a psychosomatic reaction which he himself "identified as the physical reactions to fear," as it is likely that it is through such identity that he escaped from his troubles. His "memory images" are obviously symbolic expression, which would have been better to have undergone elucidation at the time.

I hope I conflict with neither physicist nor psychiatrist when I understand that E.C.T. in this particular case acted by bringing wholly repressed material to a nearer level to conscious appreciation, and that it is probable that it is through such measures that benefit is obtained in all cases that respond to such treatment. Your correspondent's observations emphasize the further benefit to be obtained by the attendance of a psychiatrist to take advantage of the probability of such response.—I am, etc.,

Tipton, Staffs.

L. H. EUNSON.

### Causalgia of the Face

SIR,—I read with interest Mr. J. A. W. Bingham's report of two patients suffering from causalgia of the face (June 7, p. 804). Our knowledge of this condition is so incomplete that individual experience is well worth recording. I cannot agree, however,

with his conclusion, "that when sympathectomy relieves causalgic pain and tenderness it does so by interrupting the sensory pathway." It is not proved that sensory (afferent) fibres travel to the spinal cord by way of the sympathetic chain, and secondly one can see that pressure on the superior cervical ganglion can stimulate efferent fibres passing through. "Novocain" block of these fibres at a lower level would produce a temporary paralysis in their peripheral course and distribution and so prevent the occurrence of pain as noted.—I am, etc.,

Salé, Cheshire.

C. H. CULLEN.

### Reiter's Disease

SIR,—The annotation on Reiter's disease (Dec. 7, 1946, p. 865) summarizes the present state of the knowledge of this condition very well. A few points noted in four cases by me (subject of communication elsewhere) are worth mentioning. Though you have quoted several writers as correlating the disease with bacillary dysentery, Jackson's contrary opinion, which has also been quoted by you, seems to be confirmed by my four cases, none of which had any relationship with bacillary dysentery. Further, in India we see bacillary dysentery cases literally by thousands, and yet there are no authentic records of Reiter's disease. Had the two conditions been aetiologically related there would surely have been more cases of Reiter's disease in this country.

The categorical statement made by you that "... there is no relation to sexual intercourse" is not wholly correct. Kristjansen<sup>1</sup> described his case in detail in 1930 where the infection was traced to a girl of 16 who for two years had had a yellow vaginal discharge. This girl had also infected another man at about the same time, and the second victim developed only an uncomplicated urethritis lasting three months. In neither man was the gonococcus or any other organism found. The girl herself was examined and found to have had only an inflamed vagina, but gonococci were not demonstrated in her either. The sexual relationship in these two cases is clear. One of my four cases also developed the condition after extramarital coitus.

Neutrophil leucocytosis has been reported in all the cases, but one of my cases had an eosinophilia of 4 to 7% in a total leucocyte count of 11,000 to 13,000. This may mean that allergy is a factor in the disease. This case went through the gamut of bilateral conjunctivitis and polyarthritides, and the eosinophilia persisted over the earlier part of the illness. The patient did not have any parasitic infection or infestation. The possibility of allergy being aetiologically responsible is strengthened by the observation of Forbes<sup>2</sup> that his case was associated with dental sepsis. Junghans<sup>3</sup> tells about a case in conjunction with a furuncle in the upper lip, while Frühwald<sup>4</sup> described two cases, in one of which the first sign was urethritis and, in the other, joint pain in the left foot. The example of erythema nodosum being the result of a variety of infective processes may be mentioned as a possible parallel to the incidence of Reiter's disease following upon non-specific infections.

In none of the four cases observed was the complement fixation test for gonococci done, but gonococci were not found in any of the exudates by the usual staining methods. The tests were repeated many times and under varying clinical conditions.—I am, etc.,

Bangalore.

### Physical Therapy of Mental Disorder

SIR,—It seems to the mind of an ordinary physician a great pity that there should be a need for bitter and violent controversies on the subject of psychiatry; I refer to the article written by Dr. D. W. Winnicott (May 17, p. 688) and to the replies by Drs. W. Malcolm Millar, Dr. A. Spencer Paterson, Dr. A. Lionel Rowson, Dr. A. N. Hardcastle, and Dr. E. E. Feldmesser (June 14, pp. 861 and 862). Whatever the rights and wrongs of it all may be, it seems to me that always should we be able safely to look to, and to accept, the findings and dicta of fully recognized and really experienced psychiatrists.

## A LOGICAL DEVELOPMENT

in the treatment of  
**MENOPAUSAL PRURITUS**

*Combining*

PROMPT & PROLONGED LOCAL ANAESTHESIA WITH PERCUTANEOUS STILBESTROL MEDICATION

THESE distinctive properties of MENOPAX ANTIPRURITIC CREAM bring prompt relief from irritation; soothe and heal the excoriated surfaces; and provide for a more normal nutrition of the tissues by augmenting the deficient local supply of oestrogen. Indications include: pruritus vulvae, atrophic senile vaginitis, vaginal ulceration and pruritus ani.

## DIPHENAN B.D.H.

*A Non-toxic, Non-staining Oxyuricide*

Children with threadworm infestation are often subject gastro-intestinal disturbances; thus, in the treatment this condition, it is important to choose a medicament which is not likely to cause any further upset.

Diphenan B.D.H. is not nauseating, it is colourless a practically tasteless and its action on the parasite established; Diphenan B.D.H. is, therefore, the most general useful anthelmintic for use in threadworm infestation in infants as well as in children and adults. Further information will be supplied on request.

## "Isn't there something I can take, doctor?"

Pretty often-heard question in these days of food shortages. The majority of the questioners probably do feel a real need to 'take something'.

Fortunately for those whose chief trouble is lack of calories, fats and vitamins, there is now no shortage of pure cod liver oil. SevenSeaS' trawlers have been back on the job for some time, so there is plenty of SevenSeaS cod liver oil in the chemists' shops for all who need it—both liquid oil and capsules.

For some time we have been trying, through advertising, to make people realise that our sea-fresh cod liver oil is a highly nutritious fatty food—the only one available in sufficient quantity to make good the cut in the fat ration, for example. Moreover, it is the only natural source of concentrated vitamins (A and D) which is both home-produced and plentiful. We are giving as much publicity as possible to these facts, in the hope that our efforts may in some measure help the public to combat the effects of continued "belt-tightening".

STANDARD OIL: Vitamin A 20,000 I.U.; Vitamin D 2,500 I.U. per oz.  
CONCENTRATED: Vitamin A 60,000 I.U.; Vitamin D 6,000 I.U. per oz.

BRITISH COD LIVER OILS (HULL & GRIMSBY) LTD.  
ST. ANDREW'S DOCK, HULL, ENGLAND

In my opinion, for what it is worth (I am not a psychiatrist), Dr. Winnicott's article is full of flaws, of wishful thinking, and of aggression. He condemns absolutely the modern physical methods of psychological medicine and is severely taken to task for it, as he should be. If I, practising my own methods of dealing with the emotional problems and upsets in children and in their parents, do not accept the principles of child guidance, and if I disagree in the main, as I certainly do, with most child psychiatrists and do not recognize the need for many of these, I am entitled to my opinion and quite free to say so. But if out of hand I condemn the whole movement and paint it as quite absurd, I think I should expect to be regarded as aggressive and, in all probability, somewhat frustrated: and I should certainly be incredibly foolish.

I scarcely think that Dr. Winnicott would be prepared to accept without retort my own condemnation (which, however, I do not offer) of the use of psycho-analysis in children, save in those cases which I personally would regard as uncommon. I think I should expect him automatically to express the view that I knew nothing about it.—I am, etc.,

London, W.1.

MAURICE L. YOUNG.

### After-care of Psychiatric Casualties

SIR.—Most doctors are aware of the establishment about three years ago of the official after-care scheme for men and women discharged from the Services for psychiatric reasons. This scheme has been organized by the National Association for Mental Health at the request of the Ministry of Health with the co-operation of the Service Departments, and has provided social supervision for psychiatric casualties as part of an attempt to help them to readjust to civilian life—for 11,500 patients up to date. The original procedure was that the Service hospitals notified the after-care scheme of those patients who agreed to accept after-care, at the same time informing the patient's own civilian doctor. Subsequently many discharged ex-Service men and women have been brought into the scheme from a wide variety of hospitals and social agencies. In recent months, in response to many requests from other social agencies, Ministry of Labour, Pensions, and Health officials the scheme has accepted responsibility for a number of civilians who are in difficulties in ordinary life because of psychiatric disabilities. It is hoped that the experience gained in this social service will eventually be integrated into the official medical services of the State.

Whereas every effort has been made to see that the general practitioner has been fully aware of the interest of the social workers in his patient, this has not always proved possible. For instance, many patients on discharge from the service have moved to new districts and have not arranged for medical attention for many months after moving; some belong to that floating population which never remains for long with any individual doctor; others belong to the psychotic fringe hostile to any form of medical attention, yet nevertheless much in need of help. It has occasionally happened that doctors have felt that their relationship with a patient has been encroached upon by the social worker, of whose credentials they have not always been aware. In the great majority of cases doctors have been happy to use the services of our psychiatric social workers and have co-operated actively, but misunderstandings have occasionally arisen.

May I emphasize that this service is intended as an ancillary to medical measures, to aid in the patients' readjustment to life; and we regard it as of the utmost importance that good relationships should be maintained with general practitioners. Clearly, if misunderstandings occur, it hampers the efforts of both parties, and it is the patients who suffer. We have therefore arranged that each new patient referred to the scheme will be the subject of a letter written by the social worker to the doctor concerned. If the doctor has any comment to make or objection to raise he can do so at the outset, bearing in mind that after-care is a voluntary arrangement entered into by the patient himself. If doctors feel any doubts or questions about the validity of the work which the social workers are undertaking, we should be glad if they would ask the social worker concerned to call on them at their convenience to give a full explanation of what the service can offer. If further explana-

tion is needed, I and others of my medical colleagues who are active in this Association will be only too glad to get in touch with the doctors concerned.—I am, etc.,

KENNETH SODDY,

Medical Director,

London, W.1.

National Association for Mental Health.

### Factors in the Aetiology of Skin Cancer

SIR,—I should like to ask Prof. J. A. Ryle and Dr. W. T. Russell whether the conclusions to be drawn from their interesting and instructive paper (June 21, p. 873) may not be subject to certain qualifications. Their figures refer to deaths from skin cancer, but the mortality rate from that disease is very low, probably less than 2%, while the disease itself is very common and accounts for a high proportion of all primary cancers.

Prognosis in skin cancer depends largely upon the size of the lesion, and negligence is probably an important factor in relation to death from this cause. I should, in the ordinary course of events, expect neglect of a symptomless lesion to be higher in unskilled workers and labourers (IV and V of the Registrar General's social classes) than in the other groups. Do these figures therefore review a fair sample from which to assess the social or occupational factors in the aetiology of skin cancer?—I am, etc.,

Leeds.

JOHN T. INGRAM.

### Ulcerated Nasal Septum

SIR,—As medical officer to a large engineering firm, and during routine examinations of men who were working on a pickling vat containing sulphuric acid, I found that eight men were suffering from ulceration of the nasal septa. For treatment I tried petroleum jelly and lanolin, but the result was far from satisfactory. I changed the treatment after four days to cremor penicillin with "phenoxetol," and within forty-eight hours there was a definite improvement, and in twelve days with the exception of one case, the other cases were completely cured.—I am, etc.,

Birmingham.

JOSEPH RADNOR.

### Calculation of the Colour Index

SIR,—It was inevitable that the publication of Dr. R. Elsdon Dew's paper (May 24, p. 723) would lead to your receipt of at least one letter calling for the abolition of the colour index. Admirable and well-meaning though Dr. H. Levy's intention may be, the widespread adoption of his suggestions (June 21 p. 903) in routine haematology would be regrettable, as no only does the use of the haematocrit involve vein puncture in a case where the life of the patient may later depend on the integrity of that vein for blood transfusion, but it tends to convert the haematologist into a mathematical robot. Haematology, no less than clinical medicine, is a science, and diagnosis should depend on the observation and experience of the haematologist, who, noticing for example marked polychromasia, "ghost-cells," scanty platelets, and other abnormalities in a routine blood count, then proceeds to carry out reticulocyte counts, fragility and haematocrit determination, and so forth as his judgment backed by his clinical findings may dictate.

During the war years, when the country was flooded with innumerable varieties of lend-lease colour standards, each with its own level of normality, the use of the term "grammes %" was probably justifiable and even desirable. The colour index of the Haldane scale is ideally suited for routine purposes, a with certain well-known exceptions normality is represented by unity and values outside the range 0.9 to 1.05 are—give accurate counting—probably pathological and certainly worth further investigation. The colour index is also a valuable guide to treatment of anaemias, where to subject the patient to repeated vein punctures would be wholly unjustifiable. An improvement in the science of haematology should follow the lines of establishing specialist haematology departments in hospital laboratories, where the worker recognizes the abnormality by reason of his or her wide experience of the limits of normality.

Finally, the use of nomograms is to be condemned. The laboratory worker, whether he holds qualifications in medicine, science, or laboratory technology, is essentially a scientist, and any attempt to convert him into an automatic machine should be resisted at all costs. The slide rule and the centrifuge must not replace the microscope.—I am, etc.,

Liverpool.

WILLIAM K. TAYLOR.

### Temporary Hydronephrosis

SIR.—The rate at which a hydronephrosis develops is an observation which can rarely be made, but I can assure Drs. Bruce Fowler and Eric Frankel (June 21, p. 887) that recovery from hydronephrosis does occur even when it results from chronic obstruction to the outflow of urine. This is well illustrated by one of my cases of carcinoma of the prostate, which on routine pyelography was found to have a bilateral hydronephrosis of considerable size.

Difficulty in micturition had been observed by the patient for several months, and acute retention had supervened, so that it is unlikely that the hydronephrosis was of recent development when it was discovered. It was actually demonstrated ten days before a suprapubic cystotomy was performed, and the diagnosis confirmed by section. Drainage of the bladder was continued for two months, after which time, under the influence of stilboestrol, he was able to pass urine freely. Intravenous pyelograms showed no trace of the hydronephrosis, and the suprapubic opening was allowed to close.

This case was originally seen at the end of 1943, and he still remains quite well on a maintenance dose of stilboestrol, with no evidence of renal damage.—I am, etc.,

Farnborough, Kent.

C. C. COOKSON.

### State Medical Service in New Zealand

SIR.—May I, in fairness to both sides, be allowed the courtesy of your columns to add a footnote to the quotation of your correspondent, Sir Ernest Graham-Little (May 3, p. 611), from the *St. Mary's Hospital Gazette*?

I should like, in turn, to quote from a letter of Mr. Aleck Bourne which appeared in the *St. Mary's Hospital Gazette* of April-May, 1947. In this he said: "I predict that in twenty years' time the profession will look back on these past years and ask themselves how the present system of unco-ordinated muddle could ever have been allowed to exist so long as it has." This is the judgment of one of our most distinguished doctors and social reformers, who has perhaps contributed more in a practical way to the improvement of our health services than the great majority of people concerned with the new Act, whether in favour or otherwise.—am, etc.,

E. C. LIVINGSTON.

London, W.2.

Co-Editor, *St. Mary's Hospital Gazette*.

### Another Name

SIR.—It gives me great joy to see a letter from Dr. M. C. T. Leilly (June 21, p. 903) redolent of all his "mylophobia"—if I may coin a term to describe the mental attitude of those addicted to tilting at windmills. I feel as he does about the word "abmengnosia," but I am uncertain whether it is my mattering of the classics that is responsible. I feel that a word has no claim to be added to the language of Shakespeare: it is clumsy or ugly, no matter how pure its descent from nose of Plato and Cicero; and conversely that words, like roses, should not be condemned simply because they are hybrids. And "abmengnosia" seems to me to be both clumsy and ugly.

It is hard to suggest an alternative term. I for one would be occasionally to abandon Greek and Latin, and draw on our own literature: the term "Cheshire Cat Complex," conveniently abbreviated to "C.C.C.," might describe the condition, but if we must stick to the classics, could we not give up the German habit of stringing words together until the resulting error is like a train of empty goods wagons, a thing without beauty, unity, or grace? A phrase is necessary to describe this state of mind, and I suggest *Mens sibi conscia amantiae*, which seems simple enough and is already three parts familiar.—I am, etc.,

Colchester.

J. N. FELL.

\* This correspondence is now closed.—Ed., B.M.J.

## POINTS FROM LETTERS

### The Tsetse Fly

Dr. G. PRENTICE (Fort Jameson, N. Rhodesia) writes: In the *Journal* of March 22 I turned to the letter (p. 388) on groundnuts in East Africa—not because specially interested in groundnuts but because it appeared to be from my old friend, Dr. J. B. Davey—to find that it dealt with another matter in which I have great interest, to wit, the tsetse fly problem. . . . Unless game can be driven to an altitude considerably over 4,000 ft. (1,220 m.), to drive them from one area into another (unless an unpeopled area) is sheer folly. They will only increase and multiply and sooner or later repeat the spread-out we have seen under protection whenever the costly measures required to hold them back are relaxed. At an altitude of 6,000 ft. (1,829 m.) I have never seen a tsetse fly, and there are excellent and extensive areas at about that height within the tropical belt. This great adventure in the production of fats for Britain deserves everything that can be done to make it a success. The animals destroyed to make success possible need not be wasted. In place of the "anthropological experts" I suggest canning experts, and that all meat not essential to the maintenance of the workers be canned or made into biltong and shipped home. Why search the Antarctic for whale meat when Britain owns the largest ranch probably in the world? . . . In Southern Rhodesia there are those who decry the policy there pursued, feeling as they do that the slaughter of wild animals is a very sorry business. But this extensive slaughter need never have taken place had the clean territories left us by the rinderpest epidemic been retained: and early warning was given that, when the time did come for indiscriminate slaughter to save human beings and domestic stock, the blame would lie not with those who opposed protection but upon those who put sport above everything else. There are two great scourges in Africa that, left to themselves to fight it out, might do so to the benefit of mankind in the long run. One is trypanosomiasis, which kills human beings and domestic animals. The other is rinderpest, which kills domestic animals and wipes out big game. Where it sweeps a district clean of game not a tsetse is to be seen. Now, our authorities have done everything in their power to prevent or eradicate rinderpest, which only slightly affects man, and I have never known of a fatal infection. Wild animals bring along tsetse; tsetse spreads trypanosomiasis; industries are impeded and human lives lost. . . . I fancy anyone clamouring for big game protection to the present Government would be barking up the wrong tree. Well then, why not add meat to the fat which the nut scheme envisages? Pack all the meat at present on the hoof where the clearings are to be, and to save the workers and feed the home folk do the same for ten miles around the groundnut areas—a first-rate health measure for home and here.

### Shortage of Nurses

Miss JOAN MCCALLUM (London, S.W.19) writes: With reference to the letter of "Surgeon Commander, R.N." (May 24, p. 740) on the shortage of nurses: During seven years in Q.A.R.N.N.S. I frequently carried out instructional duties. I should like to point out the following facts to the Commander. (1) The orderly after his initial six weeks' training did not always enter the wards for practical experience but was allotted to non-nursing duties—i.e., pushing trolleys of medical stores, fire-watching, and messenger duties. This spoiled and deadened the enthusiasm of my keenest pupils. (2) When the orderly did enter the wards, he was at once taught to tremble and kneel down before the all-powerful god of paperwork, and so again missed practical experience. How can these men be suitable for inclusion on the *Register*? . . .

### Financial Independence

Dr. W. CRAIG (Halifax) writes: The interests of the public and the interests of medical men already in State service (this is often overlooked) depend upon a strong independent profession. Independence in the long run is only possible if this includes financial independence, and the latter disappears the moment one's total remuneration comes from one source. This explains the paradox that, while N.H.I. has on the whole been a good thing for public and profession, its 100% extension would not be a good thing, as it would mean a profession not independent but wage-slave in type. Beware of attractive initial terms!

### Tobacco

Dr. D. A. HERD (Leeds) writes: Allow me to congratulate Dr. Lennox Johnson on his excellent letter "Tobacco" (June 7, p. 827). Nowadays one sees health posters: "Spitting Spreads Disease," "Don't Cough," "Don't Spit," etc. If the public were advised "Smoke less," or better, "Don't smoke at all (except in your own house)," a great deal of the unpleasantness of smoking and spitting would be eliminated, and the benefit to health and mankind immeasurable.

## Obituary

### WILLIAM FIELDING ADDEY, M.D., F.R.C.P.

Dr. W. F. Addey died on June 20 at Otley, near Ipswich. He was born on April 23, 1872, the son of an Irish farmer; his mother was an Englishwoman. He was educated privately in Manchester, and after leaving school was taken abroad by his mother, who was then a widow. He lived in Belgium, Germany, and France, and acquired a good working knowledge of both French and German. He was in Paris during the year when the hundredth anniversary of the fall of the Bastille was celebrated. The scenes he witnessed there made a deep impression on his youthful mind and did much to confirm the liberal outlook on social questions which was characteristic of him. In 1893 he matriculated at University College. Here he came into contact with, and was influenced by, E. V. Lucas, G. K. Chesterton, and A. E. Housman.

He soon decided that the profession of medicine would offer the opportunities he sought for service to his fellows. He obtained the degrees of M.B. with honours in medicine, in 1900, B.S. in 1901, and M.D. in 1902; in 1925 he took the M.R.C.P. and ten years later was elected to the Fellowship. Addey acted as house-physician to Sir Frederick Roberts and as house-surgeon to Sir Rickman Godlee. His period of training before he went into general practice lasted for nine years, and he then joined a group of practitioners in Croydon with Dr. Parsons-Smith as the senior member. During the first world war he served for two years with the R.A.M.C. in France. When he was demobilized in 1919 he began to practise in Ipswich, where he found ample scope for applying his skill as a general and consulting practitioner. He was elected to the staff of the Suffolk and Ipswich Hospital, and later became consulting physician to it. He had been a member of the British Medical Association since 1903; and among other posts he held the office of president of the Suffolk Branch, 1932-3; representative in the Representative Body, 1934; and chairman, East Suffolk Division, 1935-6.

The claims of practice left him little time for engaging in his hobbies, the chief of which was sailing. These of his friends whom chance favoured will not soon forget the delightful experience of sailing with him in his yacht from the village of Pinmill near Ipswich to Harwich Harbour and back again between the wooded banks of the Orwell Estuary. He was fond of music, and he had a good collection of sets of the English classical authors, for he early acquired a love of literature. He keenly enjoyed foreign travel.

A friend writes, on behalf of his colleagues in Ipswich: We wish to give expression to our sense of the worth of the late Dr. Addey and of the loss we have sustained by his death. He came among us in middle life and soon made his presence felt in a way that was wholly acceptable to us. His advice was widely sought, particularly in cases of affections of the heart; he had made a special study of electrocardiography and had contributed valuable papers on the subject to the medical Press. His quick perceptions, his habit of thorough investigation, and his calm, considered judgment made him a helpful consultant. He had delightful personal attributes, including a keen sense of humour, which endeared him to all. A charming host and an equally charming guest, he combined the qualities of a great gentleman and of an able doctor. The efforts he made to carry on his work during the trying years of the recent war stand out as a shining example of tireless self-sacrifice. A serious illness about two years ago compelled him to retire from work, but after a gallant struggle he regained sufficient strength to resume his consulting practice. His end came suddenly and peacefully; after the busy life he led he has well earned his rest. We offer our sincere sympathy to his widow and two daughters in their bereavement.

Mr. DAVID JOHN EVANS, or "D.J." as he was known to so many of his associates, died on May 20. He was in his early fifties, but an extremely active clinical life had for the last ten years been interfered with by ill-health: periods of intense surgical activity, which in earlier days had been his routine, were followed by recurrences of his complaint, and yet he bore

these setbacks cheerfully. After receiving his medical education at Birmingham University, where he qualified in 1913, he served in the R.A.M.C. and then went to China. From 1922 he was assistant professor of oto-laryngology at Shantung Christian University. He returned to England after five years, but his work in the mission field had left its stamp on "D.J." and moulded his manner of life. After obtaining the F.R.C.S. in 1927 he joined the staff of the Birmingham and Midland Ear and Throat Hospital, and a year afterwards that of the Queen's and United Hospital; ill health caused him to give up the latter appointment. For many years he was aural surgeon to the Birmingham education committee and a consultant to several charitable institutions. He was honorary secretary of the Birmingham Central Division of the British Medical Association from 1930-5, and chairman of the Division in 1935-6. He had been an active member of the Association for twenty-eight years.

Dr. FREDERICK CANT, who was 85, died on May 22 at his home in Woodley, near Stockport. At the age of 22 he came from London as an assistant to Dr. Smith of Woodley after being apprenticed to Dr. New for four years. A student of Owen's College, Manchester, he qualified in 1888, and was for twelve months a resident at Stockport Infirmary. During his apprenticeship he had attended more than 200 midwifery cases, an experience which proved invaluable in his long career as a family doctor. On the death of his principal, he took over Dr. Smith's practice. In those early days he paid all his visits on horseback but was one of the first to take to motoring. He was medical officer of health for Bredbury and Romily U.D.C. for 48 years, retiring when a full-time M.O.H. was appointed in 1938. He was also district medical officer to the Board of Guardians and the Post Office, and served as medical officer for one part of the Manchester Ship Canal during its construction. Dr. Cant joined the British Medical Association in 1890 and was also at one time president of the Stockport and District Medical Society. In 1915 he was elected the second chairman of the newly formed Hyde Division, a division inaugurated on the eve of the first world war. He held office for three years and gave valuable service as chairman of the Local Medical War Committee. He acted as M.O. to the 6th Battalion of the Cheshire Volunteers. Dr. Cant was a devout churchman and for many years a churchwarden of St. Mark's Church, Bredbury.

Mr. WILLIAM EVERETT died suddenly at the Royal Hants County Hospital on June 15 at the age of 56. Mr. Everett qualified M.B., Ch.B. at Edinburgh University in 1917 and took the F.R.C.S.Ed. two years later. He had been house-surgeon at the Edinburgh Royal Infirmary and demonstrator of anatomy at the University. He was later R.S.O. at Bradford Royal Infirmary and had contributed a number of articles on surgical subjects to this and other journals. He had been a member of the British Medical Association for twenty-seven years.

K. M. R. writes: By the sudden death of William Everett the profession has been severely hit, for his technical skill and his wise and often inspired judgment placed him in the front rank. It will be difficult to replace him in the county where his work was done. For nearly twenty years he had served on the honorary staff of the Royal Hants County Hospital, Winchester, and his long and ever lengthening waiting-list spoke eloquently of his popularity. A wide circle of professional friends had grown to know his skill and ability, and to depend upon him in a way that is not often experienced. These will feel his loss acutely. This confidence was shared in a high degree by his patients, for he had in generous abundance the power to instil confidence at very short notice. His surgical judgment was unfailing, and his technical ability was of a very high order. He was a joy to watch, and a model worthy of the closest emulation. Those who have had the good fortune to work as his house-surgeons have recorded with pride and gratitude their lasting indebtedness to him. His appetite for work was hard to satisfy and remained with him even when indifferent health made his long operating lists a heavy burden. His loyalty to colleagues who had sent patients to him made it difficult for him to delegate work, and he strove to the very end to reduce the grotesque numbers on his waiting-lists, a struggle which was doomed to failure, for his popularity never ceased from growing, and as the years passed he became more and more in demand. He was a great surgeon and one who would have found himself in the front rank wherever his work was done. But he will be mourned and missed for more than professional qualities. So many will recall with gratitude his outspoken opposition to injustice. Many more will recall his loyal friendship and the ease with which he gave the benefit of the doubt to what was good, rejecting the less good. His interests were wide. In earlier days he had played golf from

## INTRAVENOUS ANAESTHESIA

with

# 'KEMITHAL' SODIUM

'Kemithal' Sodium (sodium cyclohexenyl-allylthiobarbiturate) is a new ultra-short-acting intravenous anaesthetic, evolved in the I.C.I. Research Laboratories.

In extensive clinical trials, 'Kemithal' Sodium has proved to be a highly efficient and satisfactory agent for basal hypnosis and for surgical anaesthesia of short or prolonged duration.

Having a relatively high therapeutic quotient, 'Kemithal' Sodium effects anaesthesia without undue respiratory depression. A number of workers have commented upon the reduced incidence of laryngeal spasm with 'Kemithal' Sodium.

Literature on request.

'Kemithal' Sodium is issued in ampoules of 1 gramme and 2 grammes in boxes of 5 and 25, with or without sterile distilled water in ampoules of 10 c.c. and 20 c.c. respectively. Ampoules of 5 grammes 'Kemithal' Sodium are also available in boxes of 5 and 25.

## CROOKES LACTALUMINA...

Röntgen showing site of Gastric Ulcer

The logical treatment of peptic ulcer includes the control of acidity and pepsin activity throughout the twenty-four hours.

THIS can be achieved by giving: (a) Food (which buffers the acid and uses up the pepsin) and (b) Lactalumina (which inactivates the pepsin and neutralises the acid). Lactalumina (2-4 teaspoonfuls), or food, should be given every hour throughout the day with at least two tablespoonfuls of Lactalumina at bedtime, the dose to be repeated once or twice during the night.

Full literature on request.

## NOVUTOX

Self-Sterilising  
LOCAL ANÆSTHETIC

½%, 1% & 2% SOLUTIONS

FOR

MINOR & MAJOR SURGERY

Absolutely non-toxic in therapeutic doses and tolerated by even the most sensitive tissues, Novutox has the added advantage that it possesses a remarkable chemo-therapeutic action which promotes very rapid and clean healing of wounds.

Available in:

1%, 1½% and 2% Solutions: - - - BOTTLES of 2 ozs. and 20 ozs.  
1% and 2% Solutions: AMPOULES 2 c.c. Boxes of 12 and 100.  
CARTRIDGES of 2% Solution are available in boxes of 20 and 100.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinatoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

## Vitamin Therapy -its uses and limitations

### A SINGLE SUPPLEMENT FOR SAFER PREGNANCY

Adequate safeguards against the hazards of pregnancy are now routine in practice. Among these, the provision of priority supplies of essential foods to pregnant women has had a significant effect in reducing maternal and infant mortality. Cases still occur, however, in which full advantage is not taken of these allowances. Where patients are found to be anæmic, debilitated or showing signs of sub-normality in respect of the protective factors, the simplest prescription for ensuring an adequate intake of all the necessary nutrients is that of

### PREGNAVITE

The recommended daily dose provides:—

vitamin A 4,000 i.u.	vitamin E 1 mg.	iodine	} no less than 10 p.p.m each

in sulphonamide therapy...

lower dosage

greater safety

...are provided by 'Sulfamerazine' which requires only approximately one half the usual dosage of sulphadiazine or sulphathiazole. This reduces sulphonamide therapy to simpler and more economical terms. In diseases in which four to six doses of sulphadiazine or other sulphonamides are given daily, the same therapeutic results may be obtained with a minimum of inconvenience and at proportionately lower cost, by only two to three doses of 'Sulfamerazine'.

- (1) Relatively infrequent and smaller doses are required to maintain any given plasma concentration.
- (2) The urine concentration at any given blood level is less than that of other sulphonamides in current use. For these reasons the possibility of drug concretions in the urinary tract should be less with 'Sulfamerazine' than when other sulphonamides are used.

'Sulfamerazine' is no more toxic than sulphadiazine and less toxic than sulphathiazole and sulphapyridine. It is remarkably effective in the treatment of infections caused by pneumococci, haemolytic streptococci, meningococci and gonococci. 'Sulfamerazine' is supplied in 0.5 grm. tablets for oral administration, in bottles of 50, 100, 500 and 1000. Sodium 'Sulfamerazine' sterile powder for intravenous administration is supplied in 5 grm. vials and in 50 c.c. ampoules of a 6% solution. Descriptive literature and dosage schedule on request.

**SULFAMERAZINE**

SHARP & DOHME LTD., HODDESDON, HERTS.

At an ordinary meeting of the Council of the College, held on June 12, with Sir Alfred Webb-Johnson, Bt., President, in the chair, it was announced that a Supplemental Charter had been granted to the College, giving power, among other things, to co-opt additional members of the Council, to conduct a special Final Fellowship examination in ophthalmology and otolaryngology, to grant a Fellowship in Dental Surgery, and to institute faculties in the College.

The following were co-opted members of the Council for the ensuing year: Dr. H. Guy Dain (General Practice), Mr. G. F. Stebbing (Radiology), Mr. V. E. Negus (Otolaryngology), Dr. A. D. Marston (Anaesthetics), Mr. George Black (Ophthalmology), Mr. R. V. Bradlaw (Dental Surgery), Mr. L. Carnac Rivett, subject to the result of the Council election (Gynaecology and Obstetrics).

Mr. R. J. McNeill Love was appointed as representative of the College on the British Social Hygiene Council.

Diplomas of Fellowship were granted to the following successful candidates:

J. McA. McArthur, A. S. Bullough, R. Petticrew, K. G. Rotter, A. W. L. Kessel, P. Chisholm, P. E. Hutton, S. L. M. C. Pitt, V. Crawford, G. R. Crawshaw, M. H. ... R. E. Shaw, H. M. Lewis, M. T. ... Wheelton, K. W. Wilkinson, B. B. ... P. Choyce, R. Anthonis, D. B. Brown, R. T. Campbell, M. Chaudhuri, L. P. Clark, R. L. Cooke, J. B. Curtis, E. T. Dick, J. L. Dowling, Marjorie O. Dunster, S. M. Ghosh, N. O. K. Gibbon, W. Girdwood, A. J. P. Graham, R. T. Grime, W. G. Hendry, J. P. Herdman, C. Hollenberg, B. Lewin, G. M. Lewis, E. T. McCartney, S. T. McCollum, D. McIntosh, A. M. Mair, H. L. C. Maitland, P. E. Marchand, R. P. Melville, H. D. Moore, E. J. Nangle, S. M. Nawab, G. E. Nevill, J. S. Peters, S. F. Reid, R. B. Scott, R. A. Stephen, H. D. A. Sutherland, R. A. R. Taylor, G. J. Walley.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Physicians of London, to the following successful candidates:

D. V. Bateman, O. H. Bslam, C. H. Boyd, W. H. F. Boyd, P. R. Bromage, E. K. Brownrigg, R. Bryce-Smith, J. E. Bulow, D. Canter, A. A. Cilliers, R. B. Clayton, F. E. Clynyck, S. W. Coffin, E. R. Coleman, P. B. Conroy, C. J. Corcoran, G. Curá, R. M. de Gregory, A. B. Eastwood, I. C. W. English, J. U. Forbes, A. Fraser, Eileen McC. Gibson, L. J. Goggin, J. Gordon, A. H. Grace, P. W. S. Gray, H. Grenville, J. H. G. Halliday, J. K. Harper, A. W. Hind, A. C. Holms, H. R. Hudd, G. Hughes, R. McD. S. Keir, J. Lapraik, C. H. Leveck, J. K. Lewis, Mary E. Lloyd, R. E. Loder, J. M. MacCormack, R. M. Mackenzie, R. L. McMillan, S. A. Mason, J. G. Matheson, E. T. Moersch, P. H. Moore, W. B. Neff, G. S. Ostlere, W. J. Patterson, J. Psaila, H. J. Richardson, Hilda Roberts, J. D. Robertson, F. R. Russell, C. F. Scurr, E. Thomas, T. C. Thorne, C. E. Tudor, Ambrosine B. Vaughan, Patricia E. Wallace, Mary Watson, H. L. J. Wilson, G. P. Williams, T. M. Williams, T. N. P. Wilton, E. H. Winterbottom, Luise Wislicki, R. B. Wright.

A Diploma in Medical Radio-diagnosis was granted, jointly with the Royal College of Physicians of London, to R. L. T. Hill (Glasgow).

A Diploma in Child Health was granted, jointly with the Royal College of Physicians of London, to S. Ray (Calcutta Medical School).

A series of lectures on anatomy, applied physiology, and pathology will be delivered at the College from Monday, June 30, to Thursday, July 31, and from Monday, Sept. 1, to Tuesday, Sept. 16 (Saturdays and Sundays excepted), at 3.45 p.m. and 5 p.m. each day. The fee is £16 16s. Fellows and Members of the College and Licentiates in Dental Surgery will be admitted for £12 12s. Admission cards may be obtained from the assistant secretary of the College.

#### ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the meeting of the President and Fellows of the Royal College of Physicians of Ireland held on June 6 Dr. Eamonn de Valera and Dr. J. Browne Fleming were admitted Fellows and Dr. P. M. Alston, Leslie Doyle, Leslie Fridjoh, Alan P. Grant, George Gregg, John Hayes, P. D. J. Holland, W. Dillon Hughes, Sean D. McGrath, Harry O'Flanagan, and Bethel E. R. Solomons Members of the College.

#### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College, held on May 31 with the President, Mr. W. Gilharr, in the chair, it was announced that the Rt. Hon. Field Marshal Jan Smuts, P.C., had accepted an invitation to become an Honorary Fellow.

To mark the grant of the Royal Charter of Incorporation on March 21 the following four surviving signatories to the Articles of Association, whereby the College was founded, were elected to the Honorary Fellowship: Prof. J. M. Munro Kerr, Prof. C. G. Lowry, Sir Even Maclean, and Sir William Fletcher Shaw.

The following were elected to the Council to replace those retiring in statutory rotation: As Representatives of the Fellows, D. Baird (Aberdeen), Alice Bloomfield (London), G. I. Strachan (Cardiff). As Representatives of the Members, J. A. Stallworthy (Oxford), A. M. Sutherland (Glasgow), R. J. Wotherspoon (Glasgow).

A standing committee of the Council, to be known as the Australian Regional Council, has been set up in Australia, with Dr. F. A. Maguire (Sydney) as chairman, to act as a representative committee of the council of the College in discussions and negotiations affecting the practice of obstetrics and gynaecology in Australia.

Prof. B. T. Mayes (Sydney) will act as honorary secretary of the Australian Regional Council.

The following were admitted to the Fellowship of the College:

M. D. Black, J. S. Howell, J. Jhirad, T. N. MacGregor, R. Newton, G. D. Shaw, G. S. Smyth, H. S. Waters, B. Williams.

The following were admitted to the Membership of the College:

D. Ballantine, Margaret R. Biggs, W. S. Campbell, J. B. Cochrane, S. J. Cohen, H. V. Corbett, A. Davis, J. R. Dickinson, Bessie Dodd, Morag Dods, R. C. Gilt, Jean L. Hallum, R. F. Lawrence, T. H. Lawton, J. M. McBride, R. A. E. Magee, M. K. O'Driscoll, S. S. F. Pooley, L. J. Quinn, R. B. Salter, P. C. Thomas, Kathleen M. FitzG. Worrall, J. L. Wright.

## Medical Notes in Parliament

### V.D. in British Forces

Dr. SEGAL, on June 25, discussed the incidence of venereal disease in British Forces overseas. He said the British soldier was less prone to V.D. than the soldiers of any other Allied force. He believed statistics which had been given lately in the House of Lords (*Journal*, June 14, p. 867) were unreliable, because though they dealt with incidence of the disease over 12 months per 1,000 men in a Command they failed to take account that these men were in a mobile state through postings and replacements, so that their numbers were considerably increased. The real problem was how far risks of infection had been taken for every recorded case of disease. With wide dissemination of knowledge, with well-known methods of prophylaxis and early treatment, and with a relatively low proportion of relapses and recurrences, the figures actually given were symptomatic of a general loosening of moral ties which affected many countries beside our own. He asked how the Secretary for War explained a rate of incidence of V.D. in the Far East six times as high as in the Middle East. 'Why was the rate in Germany and Austria to-day almost five times as high as in the Middle East? More could be done in regard to the branches of the Services which dealt with the moral and cultural well-being of men in the Forces, and welfare activities by civilian agencies should be encouraged more, even in occupied territories.'

Mr. JOHN FREEMAN, replying for the War Office, said Dr. Segal's approach to the problem was correct. The difficulty could only be overcome by making conditions in the Services overseas such that the temptation leading to this scourge was less likely to arise. There tended to be a periodic rise in the incidence of the disease after a war, and a peak period which the Forces had now perhaps passed. For the first quarter of 1946 the Rhine Army figures were 30.4 per 1,000; for the second quarter 41.8; for the third quarter 44.6; for the fourth quarter 41.8, and for the first quarter of 1947 30 per 1,000. He hoped the decline would be accelerated. The increase in the middle of 1946, the reduction at the end of last year, and in the beginning of this year were substantially reflected in the Commands. These were terrible figures, but lower than for a similar period after the first World War, although men were now more ready to report this disease. He could not give a clear answer to show why the incidence of the disease should be lower in the Middle East, but Service conditions there, substantially removing the men from female companionship, had a great deal to do with it. In Germany, Austria, and the Far East conditions were conducive to V.D., and its incidence among the civilian population was high. Only recently had the Army started to make progress in controlling sources of infection in the Far East. It had more civilians doing welfare work abroad than it had during the war. It was obvious that, although medical methods could limit the seriousness of the problem, the way to eliminate it was by a moral, educational, and welfare approach.

### Central Purchase of Hospital Equipment

Mr. HAYDN DAVIES, on June 26, asked the Minister of Health to what extent it was proposed to obtain equipment and supplies for hospitals under the National Health Service by centralized purchase in place of the present system of purchase by individual hospitals; and whether a similar policy would be applied to installation and maintenance services.

Mr. BEVAN answered that hospital equipment and supplies covered a wide range. For some items, there might be advantage in central purchase. But where present methods of supply and servicing worked satisfactorily it was not proposed, at the outset of the new Service, to interfere with them. For the time being central purchase would be limited to major

equipment which was in short supply, and various other items which might be found to lend themselves to central purchase on grounds of economy or better efficiency.

### Negotiations with the Minister

On June 26 Dr. SEGAL asked whether any interim report would be issued to the House on the progress of negotiations with the Negotiating Committee of the medical profession; and when this interim report could be expected.

Mr. BEVAN said there would be no such issue. He expected that these negotiations would remain confidential until the outcome was known.

Dr. SEGAL asked to be assured that if an interim report was received it would first be circulated to M.P.s rather than be issued for private circulation among 55,000 qualified members of the medical profession.

Mr. BEVAN said the negotiations were with the profession about the conditions under which they proposed to serve in a national service. They did not directly concern M.P.s. The matter was essentially one for the medical profession in the first instance and afterwards for the House of Commons if it wished.

## EPIDEMIOLOGICAL NOTES

### Food-poisoning at Birkenhead

Over a hundred people at five different parties in the Birkenhead and Wirral area were taken suddenly ill in the course of Saturday, June 28. All required treatment, and 72 were admitted to three hospitals. Except for a few cases all were discharged to their homes on the following day.

It was soon clear that the only item of food common to the four wedding parties and a child's birthday party was a large trifle. At one party 5 people in a group of 6 ate the trifle and were affected; the only one who did not eat the trifle was not affected. Further investigation showed that a woman and her child who ate the trifle after scraping off the cream which covered it were also affected. This suggested that it was the body of the trifle rather than the cream layer which was infected.

Bacteriological investigation revealed *Staph. aureus* as the organism probably responsible. It was recovered from the patients, from the trifle, and from a scone on the eye of one of the employees who prepared the trifle. Typing has not yet been completed.

### Discussion of Table

In *England and Wales* there was a fall in the notifications of most infectious diseases; the decreases included measles 2,739, acute pneumonia 87, and cerebrospinal fever 14, and the only increase of any size was scarlet fever 103.

A small rise in the incidence of scarlet fever was recorded throughout the country; the largest increase was Glamorgan-shire 27. No change occurred in the local trends of diphtheria. The only variations in the returns for whooping-cough were an increase in London 31, and a decrease in Surrey 46.

There were large decreases in the notifications of measles in many areas: the largest falls were Essex 332, Lancashire 265, Yorkshire West Riding 261, London 166, Derbyshire 147, Southampton 137, Lincolnshire 130, Middlesex 124, and Surrey 111.

Of the 12 cases of paratyphoid fever, 10 were notified in Durham (Gateshead C.B. 4, Blythdon U.D. 5, Stanley U.D. 1). A new outbreak of dysentery in Berkshire involved 18 persons Abingdon M.B. 11, Abingdon R.D. 6, and Hungerford R.D. 1).

In *Scotland* there was a decrease in the notifications of acute primary pneumonia 92, whooping-cough 37, scarlet fever 30, and diphtheria 8. Of the 39 cases of dysentery 19 were notified in Edinburgh.

In *Eire* a rise occurred in the incidence of diarrhoea and enteritis 29 and of measles 17. These rises were mainly due to the experience of Dublin C.B.

In *Northern Ireland* only slight changes were reported in the incidence of infectious diseases.

### Week Ending June 21

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 870, whooping-cough 1,07, diphtheria 220, measles 10,632, acute pneumonia 328, cerebrospinal fever 39, acute poliomyelitis 44, dysentery 47, smallpox 7, paratyphoid 11, typhoid 7.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 14.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## Medical News

### The Lister Institute

The report of the Governing Body of the Lister Institute of Preventive Medicine, which has just been published, records that the Council has re-elected to the Governing Body as its representatives Prof. H. R. Dean, F.R.C.P., Sir Paul Fildes, F.R.S., and Sir Henry Dale, F.R.S. Research units housed at the Institute are the Bacterial Chemistry Unit, the National Collection of Type Cultures, and the Blood Group Research Unit, all of the Medical Research Council, and the Blood Group Reference Laboratory of the Ministry of Health. A survey of the scientific work carried out during the year refers to Mr. Standfast's examination of the characteristics of *H. pertussis* to discover whether the organism undergoes dissociation due to inherent or environmental factors and whether these influence the potency of vaccines. Miss Spooner, studying the reactive substances found in transfusion material, has been concentrating chiefly on the liberation of histamine and adenosine from the perfused lung when such substances are given intravenously; and she and Dr. M. G. Macfarlane have been investigating the chemical changes in muscles during and after ischaemia. The results suggest that the changes leading to clinical shock after the release of a tourniquet may arise from the failure to re-establish the cycle of carbohydrate metabolism. Dr. Duthie, working with organisms of the subtilis group, has shown that the maximum production of penicillinase is obtained only when penicillin is added continuously during the growth phase of the bacteria, and he is investigating the possibility of producing an antiserum against staphylococcal penicillinase. Drs. Mackay and Kekwick have developed a procedure (suitable for large-scale production) for separating immune globulins from human plasma. Preliminary tests by the Medical Research Council indicate that the product is prophylactic against measles. Investigations into nicotinamide are being continued by Dr. Elinger and his colleagues, who have published two papers in this *Journal* (Oct. 26, 1946, p. 611, and May 17, 1947, p. 672).

### Ex-Service Nursing Orderlies

Correspondents in our columns have recently debated whether Service-trained nursing orderlies should be admitted as State registered nurses without obtaining civilian qualifications, with a view to mitigating the shortage of nurses. The Department of Health for Scotland now announces that opportunity will be given for ex-Service men and women nursing orderlies with first-class qualifications to become State registered nurses after an intensive course of one year's duration instead of the normal three years'. The General Nursing Council for Scotland will allow ex-Service men and women to sit for the examinations if they were Class I nursing orderlies, or the equivalent, in the Forces and had two years' experience of nursing under a State registered nurse. Three such courses have started at Stracathro Hospital, Angus, the Law Junction Hospital, Lanarkshire, and Ballochmyle Hospital, Ayrshire; a fourth is being planned. Temporary nursing employment before the opening of the course will be found for those who want it. Men and women in the Forces should apply through Service channels; those who have been demobilized should write to the Chief Nursing Officer, Department of Health for Scotland, St. Andrew's House, Edinburgh.

### Buckston Browne Prize

The council of the Harveian Society of London has selected "The Mental and Physical Effects of Pain" as the subject for the next Buckston Browne Prize essay. The prize, consisting of a medal and £100, will be awarded for the best essay on the above subject and is open to any member of the medical profession, under 45 years of age, registered in the British Isles or the Dominions. Essays must be submitted by Oct. 1, 1948. Further particulars may be obtained from Sir Cecil Wakeley, K.B.E., C.B., D.Sc., F.R.C.S., 14, Devonshire Street, Portland Place, London, W.1.

### B.C.G. in Norway

At a meeting of the Tuberculosis Association of Norwegian Doctors, a resolution, unanimously adopted, included this statement: "The Tuberculosis Association of Norwegian Doctors recommends to the Department for Social Affairs the promotion of proposals for a law dealing with general B.C.G. vaccination of school-children of the national schools at school-leaving age, army recruits, and other young people, as well as of other population groups which are particularly exposed to infection with tuberculosis."

### Exhibition at the Bodleian

An exhibition of books and manuscripts on medicine, surgery, and physiology has been opened at the Bodleian Library, Oxford (admission free). An illustrated catalogue (price 1s.) is available. The manuscripts include works by Hippocrates, Galen, Isaac Judaeus, Albucaasis, and Avicenna.

### R.S.M. Awards and Elections

Sir Alexander Fleming and Sir Howard Florey were joint awarded the Gold Medal of the Royal Society of Medicine on July 1. Prof. R. R. Macintosh was awarded the Hickman Medal in Anaesthesia. At the same meeting the following were elected Honorary Fellows: Sir Edward Mellanby, Dr. C. M. Wenyawer, Prof. Naguib Mahfouz Pacha, of Cairo, and Prof. Einar Key, of Sweden. The following Officers were elected for the session 1947-8: president, Sir Maurice Cassidy; immediate past president Sir Gordon Gordon-Taylor; hon. secretaries, Mr. W. A. Pool and Dr. A. T. M. Wilson; hon. treasurers, Dr. Charles Newman and Mr. L. R. Broster; hon. librarians, Mr. E. K. Martin and Dr. Thomas Hunt; hon. editors, Mr. Eric A. Crook and Dr. E. F. Cullinan.

### Visit of Czech Pathologist

Prof. Herman Siki, Director of the Department of Morbid Anatomy at the University of Prague, is visiting this country under the auspices of the British Council, and delivered a lecture on "Lesser Known Histological Methods for Routine Use in the Laboratory" at the meeting of the Association of Clinical Pathologists at Cambridge on June 27. He is attending the meeting of the Pathological Society at Newcastle on July 4-5 and will then return to London.

### Discoverers of Paludrine Honoured

Drs. F. H. S. Curd, D. G. Davey, and F. L. Rose were presented with the Gold Medal in Therapeutics of the Society of Apothecaries on June 17 at the Apothecaries' Hall by the Master of the Company Dr. C. Thackray Parsons, for the joint research which culminated in the discovery of paludrine. Dr. Davey has also been awarded the Chalmers Medal by the Royal Society of Tropical Medicine and Hygiene. At the age of 34 he is the youngest recipient of this medal.

### For Discovery of BAL

Prof. Rudolph Peters, M.C., F.R.S., who produced BAL early in the recent war, has been presented with the United States Medal of Freedom and Silver Palm.

## COMING EVENTS

### Royal Medico-Psychological Association

The 106th annual meeting of the Royal Medico-Psychological Association will be held in the Winter Garden Lecture Hall, Eastbourne, on Wednesday, Thursday, and Friday, July 9, 10, and 11, under the presidency of Dr. W. Gordon Masfield. The proceedings will open with the annual general meeting on July 9, at 11 a.m., when the officers for 1947-8 will be elected and other business transacted. At 2.30 p.m., Dr. Masfield will be inducted to the office of president and will deliver an address, and at 7.30 p.m. for 8 p.m., the annual dinner will be held at the Grand Hotel. On July 10, at 10.15 a.m., Dr. Geoffrey Evans and Dr. Noel Harris will present papers on "The Place of Psychiatry in Medicine," and at 2.15 p.m. there will be papers by Dr. Donald Stewart on "The Relation of Society to Occupational Health," and by Dr. John Thwaites on "Psychiatry in Relation to General Practice." On July 11, at 10.15 a.m., a paper by Mr. F. C. Webster, Architect to the Board of Control, and Dr. J. J. O'Reill on "The Planning of Modern Psychiatric Units," will be presented and at 2 p.m. the Child Psychiatry Section will meet at Public Health House, The Avenue, Eastbourne.

### Urology

The seventh congress of the International Society of Urology will be held at St. Moritz, Switzerland, from Aug. 25 to 28, with the following programme which shows in parentheses the names of the British contributors to the discussions. Aug. 25, "The Aetiology of Primary Renal Calculus" (Mr. H. P. Winsbury-White); Aug. 26, "The Diagnosis and Treatment of Renal Tuberculosis" (Mr. Hamilton Bailey, Dr. Cuthbert Dukes, Mr. David Band "Transplantation of the Ureter" (Mr. Arthur Jacobs). Aug. 27, general excursion and meeting. Aug. 28, "The Use of Sulphonamides and Penicillin in Urology" (Mr. J. G. Yates and Mr. Clifford Morson); "Hormone Therapy in Cancer of the Prostate" (Mr. Clifford Morson, Mr. Hamilton Bailey). Aug. 29 there will be excursions to sanatoria. Further particulars of the congress may be obtained from Mr. Clifford Morson, O.B.E., F.R.C.S., 86, Brook Street, London, W.1.

### Abernethian Society

Prof. John Fulton, Sterling Professor of Physiology in the University of Yale, will deliver an address on "Harvey Cushing and His Books" before the Abernethian Society in the Clinical Lecture Theatre of St. Bartholomew's Hospital, London, E.C., on Thursday, July 10, at 5.30 p.m.

## Presentation of Prizes

Sir Frederick Ogilvie will present the prizes in the library of the London Hospital Medical College on Wednesday, July 9, at 3 p.m.

## Pure and Applied Chemistry

The eleventh International Congress of Pure and Applied Chemistry, which the war prevented from being held in 1941, will be held in London on July 16-24, in conjunction with the also sponsored Centenary Celebrations of the Chemical Society. Lord Verhulme will preside. Further information may be obtained from the Hon. Organizer, the 11th International Congress of Pure and Applied Chemistry, 56, Victoria Street, London, S.W.1.

## Medical Hydrology

The annual meeting of the International Society of Medical Hydrology will be held at Rheinfelden, Switzerland, from Sept. 11-15, with the following programme: Sept. 11, first medical discussion, "Spa and Climatic Treatment for Children"; Sept. 12, papers on "Peripheral Vascular Disorder," followed by "Balneotherapy Non-rheumatic Diseases," at Schinznach Bad; Sept. 13, "Spa treatment in Rehabilitation after Accidents and War Injuries," to be held at Baden; Sept. 14, Further papers, at Basle; Sept. 15, beginning of excursion through the Engadine, due to last eight days, with a supplemental three days in the Bernese Oberland, if so wished. Further details may be obtained from the honorary secretary, International Society of Medical Hydrology, 28, The Circus, Bath, England.

## SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Tuesday, July 8, 6.15 p.m. Moynihan Lecture by Dr. W. K. Livingston (Professor of Surgery in the University of Oregon): Physiological Responses to Wounding. Thursday, July 10, 6.15 p.m. Hunterian Lecture by Prof. H. Jackson: Role of Anatomy in Symptomatology of Lumbar Disk Protrusions.

## POSTGRADUATE DIARY

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-2, Gray's Inn Road, W.C.—Tuesday, July 8, 5 p.m. Mr. V. E. Negus: The Nose, Nasopharynx, and Paranasal Sinuses.

## APPOINTMENTS

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—Honorary Assistant *stretic Surgeons*, H. H. Fouracre Barns, F.R.C.S., M.R.C.O.G., B. G. ers, F.R.C.S. Ed., M.R.C.O.G.

LONDON COUNTY COUNCIL.—The following in the Council's in health services are announced: in parentheses: *istants Medical Officers*, J. Aminoff (F.R.C.S. Ed.); M. W. near, M.R.C.S., L.R.C.P. (Cane, M.B., B.Chir. ley); R. M. Jones, M.B., B.S. (Long Grove). *ouis*, F., F.R.C.S., Accident and Orthopaedic Surgeon, St. Margaret's *spital and Great Western Hospital, Swindon.*

## BIRTHS, MARRIAGES, AND DEATHS

Charge for an insertion under this head is 10s. 6d. for 18 words or less. *ra words 3s. 6d. for each six or less. Payment should be forwarded with notice, authenticated by the name and permanent address of the sender. It should reach the Advertisement Manager not later than first post Monday morning.*

## BIRTHS

NES.—On June 22, 1947, at St. Anne's Nursing Home, Nottingham, to Edith (née Flinn), wife of Dr. H. G. Barnes, a daughter.

TECHER.—On June 23, 1947, at Chertsey Hill Nursing Home, Carlisle, to Edith, wife of Tom Fletcher, M.D., F.R.C.S., of Papcastle, Cockerham, son and brother for Gaim and Nigel.

FRITH.—On June 22, 1947, at the North Oxford Nursing Home, Oxford, to Lucie, wife of Dr. R. C. I. Griffiths, of Newport Pagnell, a daughter.

R.—On June 22, 1947, at Newcastle-on-Tyne, to Marie Barbara (née Ivey), wife of Dr. Leonard H. Lake, of 79, Holly Avenue, Jesmond, Newcastle-on-Tyne, 2, a daughter—Janet Havelock.

AREN.—On June 4, 1947, at Fernbrae Nursing Home, Dundee, to Pat (née Taylor), wife of Mr. L. L. Bill McLaren, R.A.F., a son—Andrew Hood.

## MARRIAGE

WYFORD—SETON.—On June 18, 1947, at Kilmarnock, Ayrshire, W. Cowan Wyford, I.R.C.S., L.R.C.P., to Mary Stewart Seton, S.R.N.

## DEATHS

WYLL.—On June 26, 1947, at Riversdale, Fielden Park, West Didsbury, Manchester, Charles Philip Brentnall, M.C., F.R.C.O.G., Honorary Surgeon, Mary's Hospitals, Manchester, aged 56 years. The very dearly loved husband of Muriel Young Brentnall.

RAY.—On June 14, 1947, at Amarah, Lower Bourne, Farnham, Surrey, American Findlay, M.D., D.Sc., F.R.C.P., in his 70th year. Funeral private. American and Canadian papers please copy.

THIRTS.—On June 17, 1947, at Bath, Francis Howard, Companion Order of St. John, Chevalier Order of Leopold I, M.D., F.R.C.P., M.R.C.S., R.C.P., D.M.R.E., L.M., formerly of 4, Stanhope Gate, Park Lane, London.

ATT.—On May 31, 1947, in Gloucester, Havelock Thos. Lippman, M.C., D.McGill, F.R.C.S. Ed.

E.—On June 22, 1947, at 60, Kewstoke Road, Bristol, 9, Ethel, wife of de Coverly Vcale.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

## Stammering

Q.—A boy aged 10 stammers badly. He started stammering at the age of 4 after removal of tonsils and adenoids. He is not a mouth-breather, and had training by an elocutionist for about a year without improvement. He is very intelligent and good at studies and games. Will you kindly discuss in detail the examination and treatment, as stammering is not discussed in most textbooks?

A.—First, any remediable physical disorders should be attended to, particularly if they are in the ear, nose, or throat area. These latter troubles do not cause stammering but they may delay the patient's recovery. Then it is essential in a young child to determine by observation which hand Nature intended him to use for his most skilled actions, and to see to it that he writes with that hand, whether left or right. Do not attempt corrective training; there is no justification whatever for forcing him to conform with the majority. If, however, the habit of writing with the non-dominant hand has been well established, any change may cause too great an upheaval. Speaking generally, the reversal can be made without serious disturbance if the child is less than 12 years old, provided that he is blessed with reasonable educators.

The next step is to induce all those coming into contact with him—and particularly parents and school-teachers—to refrain from treating the child's stammer and to ignore it so far as is possible. The teaching of elocution is likely to make many stammerers worse and it is doubtful if it is ever a help. Speech treatment can be carried out satisfactorily only by qualified speech therapists, who now form a recognized branch of medical auxiliaries and undergo a three-years training and after their final examination receive a standard diploma. The family doctor rarely has the knowledge and never the time necessary to treat this disorder. The speech treatment consists in a fairly complete re-education of the whole speech process, beginning with a "detensing" of the patient by instruction in complete bodily—and if possible mental—relaxation. Further treatment varies with the case and is too technical and detailed to outline here. In every case, however, a psychiatric survey should be made to ensure that serious psychological factors are not perpetuating the stammer. When present their treatment should be attempted at the same time as that of the speech itself. A brief outline of the problem of stammering will be found in the *Survey of Child Psychiatry*, edited by R. G. Gordon and published by the Oxford University Press.

## Psychology of Make-believe

Q.—Children between the ages of 2 and 5 are prone to pretend they are other children. My son, nearly 3, occasionally insists that he is his cousin, and that his name is Bobby and not David. He also pretends that his parents are his aunt and uncle respectively—Bobby's parents. Can this be explained by a psychologist; and is it wise to encourage this play-acting? In all other respects the child is normal and plays with friends of his own age.

A.—Young children who pretend that they are other people have a way of solving their difficulties by this means. Sometimes it is obvious how this is done; for example, when a child has an imaginary companion whom he invests with all his "naughty" characteristics, so escaping the uncomfortable sense of guilt which he would otherwise experience. In the same way it may be useful to have an extra imaginary set of parents, for children are often afraid that their angry wishes may do harm to the parents whom they love, and so they invent "whipping-boys" of various sorts. Certainly such make-believe is no sign of abnormality but a natural defence mechanism making for mental health.

### Fat Injections for Scars

**Q.**—*Can you give me any information as to the use of injections of fat for the removal of unsightly scars?*

**A.**—Injection of fat for the improvement of depressed scars is commonly used by quacks. The result is not impressive. The fat is usually absorbed or becomes a hard fibrous mass which can be felt or seen beneath the scar. The result is rarely as good as that obtained by careful excision and resuture, attention being paid to the contour and light-catching properties of the scar by building up subcutaneous tissue to secure a smooth surface.

### Fissured Lip

**Q.**—*A patient has suffered from a fissured lip at the angle of the mouth for six months. It heals for a few days but quickly breaks down. Lip salves and collodion have been tried without success. There is no oral sepsis (complete dentures), and the general health is good. Can you suggest a cure?*

**A.**—Fissures at the angle of the mouth which are infected may sometimes be induced to heal by the local use of penicillin. In intractable cases, however, where the fissure keeps breaking down, the only cure often is to excise the fissure and to suture, keeping the sutures in place for longer than the normal period to ensure that stretching of the mouth will not cause breakdown in the area before complete healing has taken place.

### Increasing the Size of the Breasts

**Q.**—*A "show-girl" is anxious to increase her breast measurements; small doses of oestrogen and progesterone have no effect. Is this a safe treatment and is it likely to be effective? If so, what dosage should be given and at what intervals? There is a history of salpingectomy in 1932 when she was 19, both ovaries were left in situ. Would this influence the effect of the treatment?*

**A.**—It is usually possible to produce breast enlargement with oestrogens, providing the breast tissue is inherently capable of response and an adequate dose is given. The effect might be enhanced by giving progesterone in combination with oestrogen, but progesterone alone is unlikely to be of value. However, oestrogen therapy, either local or systemic, is not advised because its effect is temporary and when it is withdrawn the breasts not only return to their former size but tend to be less firm and shapely. The changes are rather like those occurring in pregnancy, including darkening of the areola and increased vascularity; afterwards the breasts assume the appearance of those of a multipara. Moreover, the increased size cannot be maintained by giving oestrogens for an indefinite period because ill effects, such as menstrual disturbances, endometrial hyperplasia, pituitary and ovarian depression, and breast changes similar to those of "chronic mastitis," may occur. As an alternative to hormones, physiotherapy should be tried, especially arm exercises to develop the pectoral muscles and increase the blood supply to the breasts. Swimming might be particularly effective. The advantage of this type of treatment is that it can be continued regularly for an indefinite period. Salpingectomy does not affect the breasts.

### Scabies Infection of Anus

**Q.**—*Have scabies mites been noted in the rectum or urine? Inquiries show that most cases of infection in Natal are due to natives sleeping in sacking, and that the parasite is often found around the anus.*

**A.**—The scabies mite has only been found living in the horny layer of the skin and never in the internal organs. Very occasional dead and partly macerated specimens have been demonstrated in the urine and sputum, but this was almost certainly due to contamination. It would be interesting to know just what the questioner means when he states that "inquiries" reveal that infections with scabies in Natal are usually due to natives sleeping in sacking. All other investigators have shown that, while an occasional infection from fomites may occur, transmission is due in the majority of cases to personal contact. Coarse material like sacking would be most unlikely to harbour *Sarcoptes* in any numbers. Was the alleged heavy infection with parasites round the anus confirmed by finding the mites

themselves? Other investigators have found that, while impetiginous lesions are common in the buttocks, a comparatively small number of mites occur in this region, while much larger numbers, giving rise to few clinical symptoms, are seen on the hands and wrists.

### Renal Function Tests

**Q.**—*Is it possible to correlate specific renal function tests with specific renal lesions; for example, the water concentration test with damage to the tubules?*

**A.**—Although renal function tests are helpful in assessing the state of the kidneys, our knowledge of renal function is not yet sufficient to allow of our correlating specific renal function tests with specific renal lesions. Too many imponderables exist to make this possible. Theoretically it would seem that the water concentration test would throw light on the state of the kidneys, but too much weight should not be attached to the findings. It is quite possible that, with an increase of knowledge of the physiology of the kidneys, what is now theoretical may become practical.

### First Pregnancy after Nephrectomy

**Q.**—*A patient, aged 40, just married, is anxious to have a child. She had one kidney removed at an early age. What are the hazards of a first pregnancy under these conditions?*

**A.**—Although many women with only one kidney go through pregnancy without suffering any ill effect, the combination of conditions must always give rise to some anxiety because the safety margin is small. The outlook in any case depends to some extent on the indication for the nephrectomy, and especially on the health and efficiency of the remaining kidney. Before advising this woman, renal function tests and also pyelography should be carried out. If the results are satisfactory the patient should be told that in the event of her becoming pregnant she will require careful supervision. The chief risks are pyelitis and any sort of toxæmia, and if these occur and do not respond immediately to conservative measures the pregnancy should be terminated.

### Hormones and Carcinoma of Prostate

**Q.**—*Is there any proof that testosterone has converted a benign growth of the prostate into a malignant one? In view of the fact that stilboestrol causes regression the possibility seems obvious.*

**A.**—There is no proof or indication, either clinical or experimental. The inhibitory action of stilboestrol on carcinoma of the prostate does perhaps raise the possibility, as do also the hypertrophy and hyperplasia of the prostatic epithelium which result from testosterone administration under certain conditions. However, apart from the absence of objective direct evidence, it is recognized that there is a malignant neoplastic stimulus (of uncertain character), as well as a hormone stimulus, involved in the induction of carcinoma of the prostate. Thus Huggins found that even when bilateral adrenalectomy was superimposed on bilateral orchidectomy, so that all androgenic stimulation was eliminated, a relapse from carcinoma of the prostate could not be halted indefinitely.

### Urinary Incontinence

**Q.**—*A male aged 34 complains of urinary incontinence, which started four years ago. The condition was first noticed at night and has become progressively worse. Examination of urine, urinary tract, and bladder has proved negative. Belladonna and ergot pills have been of help; is there any danger in their prolonged administration? What further treatment and investigations do you advise?*

**A.**—The diagnosis in this case is obscure and little can be said about treatment until it has been elucidated. The symptoms might fit in with a prostatic lesion, but the patient's age makes the presence of an ordinary enlargement extremely improbable. It is possible, however, that he has what the American urologists call a "prostatic bar"; this is generally missed by the inexperienced cystoscopist. It is important to know whether there is any residual urine, and a catheter should be passed after he has made every effort to empty his bladder.

It is quite likely that residual urine will be found and that this accounts for the lack of control. A small perurethral resection would then probably bring about great improvement. It is to be assumed that the possibility of a lesion of the central nervous system has been eliminated. In this case the incontinence first became marked by night, and it is unlikely, therefore, that it is functional. There is no objection to continuing the only treatment which so far has been effective.

#### Acute Rheumatism and the Heart

**Q.**—Cases have been reported in America of cardiac damage following acute rheumatism treated by salicylates. I understand that rheumatic fever in an adult does not cause permanent cardiac damage provided the heart was previously healthy. At what age can it be assumed that rheumatic fever is unlikely to inflict permanent damage on the heart?

**A.**—Cardiac involvement probably occurs in every case of acute rheumatic fever or acute rheumatism, and this may lead to permanent cardiac damage. Neither the incidence of cardiac involvement nor the tendency to permanent damage appears to be influenced by the administration of salicylates in any form. First attacks of rheumatic fever are less likely to inflict permanent damage in subjects over 15, and in subjects over 20 the risk is slight. However, any prognostic assessment on these grounds is unwarranted unless the full clinical picture is borne in mind. In addition, it would be unwise to assume that the benign course of adult cases will be an unchanging feature of the disease for all time.

#### Wassermann Reaction of Cadaver Blood

**Q.**—On admission to hospital a patient's Wassermann reaction was negative. At the subsequent necropsy a Wassermann test done on blood taken from the body gave a positive reaction. This result was held to be valueless, as blood from a cadaver is always Wassermann positive. If this is correct, what is the explanation?

**A.**—Cadaver blood occasionally, but not invariably, gives a false positive Wassermann reaction; not uncommonly serum obtained from a corpse is anticomplementary. There is no satisfactory explanation of either phenomenon. In view of the fact that the reaction was negative during life and positive after death, it should be borne in mind that a considerable proportion of false positive results of Wassermann tests done in this country are due to faulty technique or inexperience.

#### Sulphonamides and Mepacrine

**Q.**—What are the incompatibilities of the sulphonamides and f. mepacrine when administered by the oral route? Do these drugs damage the liver? Can they be given together without fear of incompatibility or liver damage? If not, how can these risks be overcome?

**A.**—Para-aminobenzoic acid should not be given with sulphonamide drugs because of therapeutic interference, and it is advised that saline purges, thiopentone, phenazonum, midopyrine, phenylhydrazine, gold, and arsenical compounds be avoided when sulphonamides are being given. Some recommend that pamaquin should not be given with mepacrine. In practice, however, there are few serious incompatibilities of sulphonamide drugs or mepacrine given orally. In therapeutic dosage their damaging effect on the liver is negligible. Sulphapyridine and mepacrine may be given together.

#### Eclampsia a Toxaemia ?

**Q.**—What evidence is there for the toxaemia theory of eclampsia? Have samples of systemic or portal blood from such cases ever been given to other individuals, or to experimental animals, with the production of significant symptoms?

**A.**—The view that eclampsia is a manifestation of a toxaemia was elaborated during the late nineteenth and early twentieth centuries. It was based on observations such as the following: regenerative changes in various organs, especially liver and kidney, were rather similar to those produced by chemical poisons; the wide distribution of lesions suggested that the causal agent was in the circulation; the occasional finding of

what were considered similar lesions in the foetus was also thought to favour the idea of a toxin which had crossed the placenta; the organ most constantly found to be damaged was the liver. Nevertheless, a toxin has never been demonstrated and, if there is one, its origin remains unknown. Systemic blood, serum, urine, and extracts of placentae from eclamptic women have been injected into various laboratory animals, and numerous experiments of this kind are reviewed by J. Whitridge Williams in *Obstetrics*, 4th edition, 1920. What were at first thought to be significant effects in the animals were later shown to be serum and foreign-protein reactions. Further and better-controlled experiments of this kind did not provide evidence of the presence of any special toxin. Systemic blood from women suffering from eclampsia has also been transfused into women suffering from haemorrhage, without producing any special symptoms. J. B. deLee in the 4th edition of *The Principles and Practice of Obstetrics* mentions that Bumm carried out work of this kind in 1922.

### NOTES AND COMMENTS

**Leuconychia.**—Dr. ALICE E. B. HARDING (London, S.W.) writes: Belatedly reading the *Journal* of May 17, I have seen the answer on leuconychia (p. 705) and find it unacceptable. Some years ago I noticed that though my finger nails are patterned to an unusual extent with transverse white marks, my toe nails show no linear deposits at all. I considered the question of exposure to light as one of the possible factors, and to test this theory I kept my finger nails painted with a deep-coloured nail varnish for three months. The varnish was removed as necessary with acetone and reapplied with the usual soft brush. The white markings gradually faded, and at the end of the three months had gone completely. During this time my cuticle toilet was carried out as usual each night. When I finally (and thankfully) discarded the varnish, many marks returned within a week; their number and size seem to vary with the general state of my health, and are greater during the winter than the summer, when, as is the case with every doctor, I am more apt to be "run down" and tired. It would seem that there is a constitutional factor concerned, but that the actual deposition is determined by exposure to light.

**"Susceptibility" to Lousiness.**—Dr. K. M. TOMLINSON (Leamington Spa) writes: In your expert's reply (June 14, p. 871) upon the above subject he postulates that those people who consider themselves more susceptible to flea bites are the more sensitive by nature and therefore more likely to notice bites. In Southern California in the dry season flea bites cause considerable and widespread distress to susceptible patients. Howard Eder reports that all susceptible patients treated with large doses of thiamine hydrochloride (he used 10 mg. three times a day to begin with, and then a maintenance dose of 10 mg. daily) obtained relief while so saturated. On desaturation he noted that their susceptibility returned, but relief was again obtained on further treatment. It was my intention to try the effect of thiamine saturation on patients with other infestations, such as scabies, to note whether the irritation became less. This would infer a similar distaste for thiamine on behalf of the acarus. The timely warning of the toxicity of thiamine hydrochloride by Reingold, Haley, Fleischer, and others dissuaded me from experiment in such a relatively simple and easily cured ailment as scabies. It might, however, be worth while for any medical man who is markedly susceptible to fleas, mosquitoes, etc., to try the effect of thiamine hydrochloride on himself. Fortunately I am not a suitable guinea-pig.

SUPPLEMENT TO THE

LONDON SATURDAY JULY 5 1947

## REGIONAL HOSPITAL BOARDS

## CHAIRMEN AND MEMBERS

In December last (*Journal*, Dec. 28, 1946, p. 1000) the Minister of Health defined the areas for which Regional Hospital Boards would be responsible under the National Health Service Act. On June 27 he published an order setting out the constitution of these Boards. The Boards will organize and develop the hospital and specialist services in their respective areas, though ultimate control will remain with the Minister. The Boards will later appoint Hospital Management Committees for the local administration of all hospitals except teaching hospitals. The chairmen have been appointed for a period ending March, 1950; one-third of the other members will retire at the end of each year beginning in March, 1949. They will be eligible for reappointment, and the term of office of future members will be three years. All the appointments are honorary. We list below the chairmen and members of the Boards.

## Chairmen

Newcastle Area: Sir Walter Thompson (chairman of Newcastle-upon-Tyne C. B. Health Committee). Leeds Area: Mr. J. E. Fattorini (chairman of Bradford Infirmary). Sheffield Area: Sir Basil Gibson (formerly Town Clerk of Sheffield). East Anglian Area: Lord Cranbrook (councillor, E. Suffolk C.C.). N.W. Metropolitan Area: Mr. F. Messer, M.P. (chairman of Middlesex C.C.). N.E. Metropolitan Area: Mr. J. W. Bowen (formerly chairman of Mental Hospitals Committee of the London C.C.). S.E. Metropolitan Area: Mr. K. I. Julian (chairman of Royal Sussex Hospital, Brighton). S.W. Metropolitan Area: Mr. F. H. Ellison (chairman of Surrey C.C. Public Health Committee). Oxford Area: Dr. A. Q. Wells (chairman of the Oxon C.C. Public Health Committee). South-western Area: Mr. H. G. Tanner (treasurer, University of Bristol). Welsh Area: Sir Frederick J. Alban (secretary and comptroller of the Welsh National Memorial Association). Birmingham Area: Mr. R. R. Adam (chairman of the Worcester - C.C. Public Health Committee). Manchester Area: Sir John Stopford (Vice-chancellor of the University of Manchester). Liverpool Area: Mr. T. Keeling (chairman of the Management Committee of the Royal Southern Hospital).

## Members

*Newcastle Regional Hospital Area.*—Mr. E. F. Collingwood, C.B.E., J.P.; Mr. D. C. Dickson, F.R.C.S.Ed.; Dr. T. H. Bates: Dr. W. Fraser; Ald. A. Cooper; Mr. T. Benfold, C.B.E., J.P.; Mr. T. A. Wright; Mr. J. A. Hutchison; Mr. J. Foster; Mr. R. Muckle; Lord Eustace Percy; Prof. R. B. Green (Dean and Professor of Anatomy, University of Durham); Prof. W. E. Hume, C.M.G. (late Professor of Medicine, University of Durham); Dr. J. R. Murray; Mr. W. Waddell; Mr. T. C. Sqaunce, O.B.E.; Viscountess Ridley; Lord Westwood, O.B.E.; Miss D. R. Gibson (Matron, General Hospital, Newcastle); Prof. F. J. Nattrass (Professor of Medicine, University of Durham); Dr. G. P. Milne, M.R.C.O.G.; Dr. R. E. Jowett; Ald. J. Cohen, J.P.; Ald. A. J. Best, J.P.; Ald. P. S. Ilanckock, O.B.E.; Mr. G. D. Cochrane, J.P.; Mr. J. Oliver; Mr. T. B. Harston; Mr. L. Bird, M.B.E.

**Leeds Regional Hospital Area.**—Prof. M. J. Stewart (Professor of Pathology, Dean of Medical Faculty, University of Leeds); Dr. D. C. Muir; Dr. W. S. MacAdam; Ald. L. Chambers; Ald. A. Sugden, J.P.; Mr. L. Crowther, O.B.E., J.P., Ald. H. J. Bambridge, O.B.E., J.P.; Miss M. F. Dykes (Matron, St. James's Hospital, Leeds); Prof. A. M. Clay (Professor of Obstetrics, University of Leeds); Mr. G. W. Black, F.R.C.S.; Dr. J. L. Russell; Ald. D. Bevers, J.P.; Mr. H. Denham; Mr. W. L. Lawton; Mr. B. Hazell, M.B.E.; Prof. R. E. Tunbridge, O.B.E. (Professor of Medicine, University of Leeds); Dr. W. S. Macdonald, M.C., J.P.; Mr. D. Watson, F.R.C.S.; Ald. R. E. Smith; Mr. A. Walker; Mrs. I. B. Shaw; Mr. S. C. Fryers; Mr. J. C. Hunter.

*Sheffield Regional Hospital Area.*—Prof. E. J. Wayne (Professor of Pharmacology and Therapeutics, University of Sheffield): Dr. J. W. Brown; Mr. A. W. Harrison; Ald. E. Sheerins; Mr. C. K. Hobson; Lord Quibell; Ald. C. F. Bowmer; Ald. H. Deer, J.P.; Mrs. F. J. Everard; Miss A. Wetherell; Prof. G. L. Roberts (Professor of Dental Surgery, University of Sheffield): Miss M. G. Bott, F.R.C.O.G.; Dr. K. K. Drury, M.C.; Dr. J. P. W. Jamie, M.C.; Ald. R. Shaw, J.P.; Ald. W. E. Yorke, J.P.; Mr. A. R. Martin; Mr. T. Pearson; Mr. E. W. Scorer, O.B.E.; Mr. R. E. Dewberry; Mr. J. L. A. Grout, M.C., F.R.C.S.; Mr. E. F. Finch, F.R.C.S.; Dr. A. B. Slack, M.C.; Ald. W. Bayliss, J.P.; Mrs. G. Buxton, J.P.; Mr. G. H. Round, J.P.; Mr. H. Ford; Mr. W. B. Jarvis; Lieut.-Col. N. G. Pearson, D.S.O., M.C.; Mr. M. Brown.

*South-east Metropolitan Regional Hospital Area.*—Mr. S. J. Worsley, D.S.O., M.C.; Mr. J. R. H. Turton, F.R.C.S.; Dr. H. A. Freble; Dame B. Lambert, D.B.E.; Mr. F. W. Chambers, O.B.E.; Ald. R. H. Burslem; Rev. H. Samuel; Ald. T. E. Morris; Dr. E. R. Boland, C.B.E. (Dean, Guy's Hospital Medical School); Mr. F. E. Feilden, F.R.C.S.Ed.; Dr. A. T. Rogers; Ald. Miss A. Hudson, M.B.E.; Lord Cunliffe; Mr. E. C. Sherwood; Miss E. K. N. Cumming; Mr. J. B. Hunter, C.B.E., M.C., F.R.C.S. (Dean of Faculty of Medicine, University of London); Dr. W. G. Masfield; Mr. C. W. Brook; The Hon. R. B. Buckley; Mr. W. Kelsey Fry, C.B.E., M.C., L.D.S.; Mr. W. C. H. Luckett; The Hon. Mrs. S. L. Henley; Ald. S. C. C. Harris.

*South-west Metropolitan Regional Hospital Area.*—Mr. P. H. Mitchiner, C.B., C.B.E., F.R.C.S.; Mr. J. M. Wyatt, F.R.C.S.; Mr. N. E. Waterfield, F.R.C.S.; Ald. A. E. Allaway; Ald. Col. C. H. Gibson; Sir Arthur Watson, C.B.E.; Ald. F. J. Wooley; Mr. J. A. Tulk; Miss E. C. Batho; Mr. M. F. Nichols, C.B.E., F.R.C.S. (Dean, St. George's Hospital Medical School, London). Dr. D. Curran; Dr. C. B. S. Fuller, M.C.; Ald. A. Lubbock; Mrs. H. Feeling; Mr. J. L. Williams; Miss P. Loe, M.B.E. (Matron, St. James's Mental Hospital); Mr. G. H. Macnab, F.R.C.S. (Dean, Westminster Hospital Medical School); Dr. D. Stark Murray; Mr. N. F. Adeney, F.R.C.S.; Mr. R. Sargood, M.P.; Mr. A. G. Linfield, O.B.E.; Mr. A. Hague-Winterbotham; Mr. E. F. Crundwell; Mr. G. E. Coke; Mr. G. Thompson.

*Oxford Regional Hospital Area.*—Prof. A. D. Gardner (Professor of Bacteriology, University of Oxford); Dr. J. S. I. Skotowe; Lord Hcnley; Mr. A. J. B. Selwood; Mr. E. C. Bevers; Mr. P. C. Raffety; Ald. Mrs. A. Jenkins; Miss R. R. Jolliffe; Prof. A. W. M. Ellis (Regius Professor of Medicine, University of Oxford); Mr. J. A. Stallworthy, F.R.C.S.; Dr. D. S. Jones; Mr. A. R. Banham, F.R.C.S.; Miss R. Spooner; Col. C. B. Krabbe, O.B.E.; Rev. J. D. Turner; Prof. H. J. Seddon (Professor of Orthopaedic Surgery); Sir Oliver S. Franks, K.C.B.; Mr. A. Woodley; Mr. W. R. Robins; Mr. L. M. Paterson; Miss C. Adams; Dr. Janet Vaughan (Principal, Somerville College, Oxford).

*East Anglian Regional Hospital Area.*—Mr. T. S. Hele; Dr. R. Ellis; Dr. J. V. Morris; Ald. Mrs. M. Whitmore; Miss J. G. Thompson (Matron. E. Suffolk and Ipswich Hospital); Mr. P. F. Dennard; Mr. C. R. Caselton; Mrs. H. A. Adrian, J.P.; Mr. J. Grantham; Mr. M. W. B. Bulman, F.R.C.S.; Dr. R. B. Fawkes, D.S.O., M.C.; Ald. S. Peel, J.P.; Ald. W. Brown; Ald. J. Brooks-Bank, J.P.; Mr. E. W. Plumptre, J.P.; Canon J. D. Day; Mr. W. B. Gourlay, M.C.; Mr. R. W. Butler, F.R.C.S.; Mr. J. B. Coster, J.P.; Mrs. E. Binfield; Mr. R. H. Parker, M.C.; Mr. R. B. Keefe; Sir Cecil Oakes; Mr. O. Chivers; Mr. W. H. York.

*North-west Metropolitan Regional Hospital Area.*—Dr. H. E. A. Boldcro (Dean, Middlesex Hospital Medical School); Dr. H. Joules (Medical Superintendent, Central Middlesex County Hospital); Mr. A. C. Morson, O.B.E., F.R.C.S.; Mrs. F. M. Baker, C.B.E.; Ald. Mrs. Martin-Smith, M.B.E.; Col. The Hon. J. J. Astor; Mr. H. Fletcher; Miss V. Dart; Dr. H. W. C. Vines (Dean, Charing Cross Medical School); Dr. S. J. Cowell (Vice-Dean, University College Hospital Medical School); Dr. J. R. Rees, C.B.E.; Mr. A. S. Gough, F.R.C.S.; Miss E. Rickards; Mrs. F. M. Suggate; Sir Owen Mershhead, K.C.V.O., D.S.O., M.C.; Mr. H. Lesser.

O.B.E.; Prof. J. M. Mackintosh (Professor of Public Health, London School of Hygiene); Miss E. Cockayne (Matron, Royal Free Hospital); Mr. G. B. Jeffery; Dr. K. G. Lloyd-Williams (Dean, London School of Medicine for Women); Dr. D. H. Brinton (Dean, St. Mary's Medical School); Mr. L. W. Plewes, F.R.C.S.; Mr. R. Siamp; Ald. H. R. Neale; Sir A. H. Maxwell; Mr. A. G. de Rothschild; Dr. Stephen Taylor, M.P.; Mr. F. J. Ballard.

*North-east Metropolitan Regional Hospital Area.*—Mr. S. Hastings, M.P.; Ald. S. F. Johnson; Mr. E. T. Nethercoat, C.B.E.; Mr. C. S. B. Wentworth-Stanley; Mrs. H. M. Blair-Fish; Capt. H. Brierley, O.B.E., M.C.; Mr. C. C. Carus-Wilson, M.C.; Ald. C. E. S. Blackmore; Prof. S. P. Bedson (Professor of Bacteriology, London Hospital); Dr. R. Strom-Olsen; Dr. H. M. M. Mackay; Lieut.-Cmdr. H. Denton; Mr. L. Conyns, M.P.; Major R. P. Woodhouse; Dr. G. Graham; Mr. R. W. Reid, F.R.C.S.; Dr. R. Poots; Mrs. A. L. Hollingsworth; Mr. W. V. Wakefield; Mr. H. W. Butler, M.P.; Ald. C. H. Simmons.

*South-western Regional Hospital Area.*—Dr. S. McClements; Dr. R. E. Hemphill; Mr. J. W. G. H. Riddell, M.C., F.R.C.S.Ed.; Ald. J. J. Milton; Ald. W. Barrett; Ald. Mrs. J. M. Phillips; Mr. A. L. Candler; Mr. C. P. Brown; Mr. J. R. Makeig Jones; Miss R. C. Shackles (Matron, Royal United Hospital, Bath); Sir Philip Morris, C.B.E.; Dr. W. Niccol; Dr. C. T. Andrews; Col. H. B. Stokes, M.B.E.; Mrs. K. A. Goddard; Mr. P. E. Russell; Mr. E. Cadbury, D.S.C., D.F.C.; Brig. J. Morrison, M.B.E.; Mr. A. C. Bowden, L.D.S.; Prof. R. J. Brocklehurst (Professor of Physiology, University of Bristol); Prof. R. M. Walker (Professor of Surgery, University of Bristol); Dr. C. J. Fuller; Mr. S. C. Morland; Mrs. J. Marshall; Ald. H. G. Mason; Mrs. M. F. Williams; Mr. G. G. Gilmour-White, O.B.E.; Miss M. F. Awdry.

*Welsh Regional Hospital Area.*—Prof. E. A. Owen (Professor of Physics, University of Wales); Mr. R. D. Aiyar, F.R.C.S.Ed.; Mr. A. H. Coleman, O.B.E., F.R.C.S.Ed.; Dr. H. G. Davies; Ald. E. A. Cross, M.B.E.; Ald. R. Gronow; Rev. B. Waldo-Lewis; Mr. R. Davies; Mr. A. S. W. Johnson; Ald. T. J. Kerrigan; Mrs. E. Owen; Ald. J. Dicks; Prof. O. H. Williams (Emeritus Professor of Surgery, Liverpool University); Dr. D. H. Pennant, D.S.O.; Ald. W. C. Davies; Ald. J. J. Panes, O.B.E.; Mr. H. Alexander; Mr. T. P. Davies; Ald. W. Casey; Dr. I. J. Davies; Prof. R. M. F. Picken (Professor of Preventive Medicine, Acting Provost, University of Wales); Prof. T. B. Davie (Dean of Medical School, Liverpool University); Dr. J. H. O. Roberts; Mr. J. Ll. Davies, O.B.E., F.R.C.S.Ed.; Ald. the Rev. W. D. Thomas; Mr. T. McDonald; Mr. W. J. Canton; Mrs. K. W. Jones-Roberts; Mr. W. Evans; Mr. H. T. Edwards; Ald. T. Evans.

*Birmingham Regional Hospital Area.*—Prof. Sir L. G. Parsons (Dean of Medical School, University of Birmingham); Prof. H. F. Humphreys, O.B.E., M.C. (Professor of Dental Surgery, University of Birmingham); Mr. N. Duggan, F.R.C.S.; Dr. J. J. O'Reilly; Mrs. A. L. Barker; Capt. L. H. Green, M.B.E.; Mr. A. Smith; Mr. W. T. Smith; Major O. Hotchkiss; Mr. H. S. Wailes; Dr. R. E. Priestley, M.C.; Mr. L. A. Dingley, F.R.C.S.; Dr. J. A. Brown; Mr. J. Latham; Sir E. J. Johnson; Mr. E. T. Hobley; Ald. L. Whitehouse; Miss Smaldon; Mr. G. A. Thompson; Prof. A. P. Thomson, M.C. (Professor of Therapeutics, University of Birmingham); Dr. J. H. Sheldon; Mr. A. J. Watson, F.R.C.S.; Mr. D. J. Evans; Ald. A. F. Bradbeer; Ald. W. L. Dingley; Mr. V. W. Grosvenor; Mr. L. E. Bury; Mr. C. O. Langley.

*Manchester Regional Hospital Area.*—Dr. W. Briggs; Prof. D. Dougal (Professor of Obstetrics, University of Manchester); Ald. T. Halstead; Sir Thomas Tomlinson; Major E. F. Pilkington; Ald. J. Eastham; Mr. G. Gibson, C.H.; Miss L. G. Duff-Grant (Matron, Royal Infirmary, Manchester); Mr. N. G. Frank; Mr. C. N. Skinner; Prof. H. S. Raper (Professor of Chemical Physiology, Dean, University of Manchester); Dr. J. D. Ailverston; Dr. S. Hodgson, J.P.; Mr. W. Onions; Mrs. E. A. Watson; Ald. G. D. Hastwell; Mr. F. W. Boggis; Mr. J. Fielding; Prof. G. Jefferson, C.B.E., F.R.S. (Professor of Neurological Surgery, University of Manchester); Mr. R. L. Newell, F.R.C.S.; Prof. H. Platt (Professor of Orthopaedic Surgery, University of Manchester); Mr. F. Bussy; Mr. A. Cook; Ald. J. Shorroek; Mr. W. A. Davies, C.B.E.; Mr. J. Sillavan; Mrs. F. A. Ogden; Mr. E. Hall.

*Liverpool Regional Hospital Area.*—Mr. J. F. Mountford; Prof. H. H. Siones (Professor of Dental Surgery, University of Liverpool); Mr. D. R. Owen, F.R.C.S.Ed.; Dr. T. H. Harker; Mr. E. Smethurst; Mr. A. Parkin; Ald. D. Plinston; Miss D. C. Keeling, O.B.E.; Miss M. Jones, O.B.E.; Prof. H. Cohen (Professor of Medicine, University of Liverpool); Dr. J. E. Nicole, O.B.E.; Miss A. L. Bulley; Mr. H. D. Ellidge; Mr. W. S. Rhodes; Mr. T. W. Harley, M.B.E., M.C.; Prof. A. L. Robinson (Emeritus Professor of Obstetrics and Gynaecology, University of Liverpool); Prof. T. B. Davie (Dean of Medical School, University of Liverpool); Prof. W. M. Frazer, O.B.E. (Professor of Public Health, University of Liverpool); Mr. F. Bidston; Ald. N. Birch; Miss A. D. Eills, M.B.E.; Mr. J. Taylor; Mr. E. E. Ashion.

## MEDICAL ORGANIZATION IN DENMARK GENERAL PRACTICE

BY

K. H. BACKER

Medical Adviser to Department of Health

The development of medicine in Denmark has involved the working power of general practitioners being employed to a great extent in organizing out-patient care. The specialization of medical science, in itself likely to counteract this development, has resulted in an organized collaboration between the specialists and the general practitioners, the position of the latter being maintained as the bed-rock of out-patient care. The fact that the sickness benefit clubs, as supporters of the social sickness insurance, could already bring their influence to bear towards the end of the last century has been a determining factor of this development.

In 1892, with State approval, the sickness benefit clubs were obliged to grant their members *free* medical care by general practitioners, whereas medical care given by specialists was a voluntary benefit. The obligation to grant *free* medical care debarred the sickness benefit clubs from confining themselves to covering the expenses of the members in part according to the refundment scheme. This obligation forced them to enter into contracts with the doctors, and these contracts were made with the general practitioners. As the number of sickness benefit clubs increased—they now include three-quarters of the population—the position of the general practitioners became more important. One reason was that the number of specialists at the outset was so small that the out-patient care could base itself on their co-operation to a small extent only; besides, specialist care was more expensive than general-practitioner care.

The contract negotiations between sickness benefit clubs and doctors gave the latter a share in determining the organization of out-patient care. It was conducive to the general practitioners' keeping their central position, even after specialization within medical science had grown apace. To some extent, I suppose, it was due to the numerical superiority of the general practitioners—you could not do without them—but it was also due to systematic endeavours to organize the medical care service on the "family doctor" principle. This principle has been and is accepted unanimously by general practitioners and specialists as well as by the sickness benefit clubs.

### The Family Doctor

According to the "family doctor" principle each family has its regular doctor, a general practitioner, to whom the members of the family always apply first for medical care. On his advice and reference a specialist may be consulted; when the specialist treatment has been finished, the patient is sent back to his family doctor with an account of examinations and treatment, if any. The same mode of procedure is adopted by hospitals and similar institutions in relation to the doctor admitting the patient to the hospital—normally the regular doctor of the family. This scheme has some advantages and some disadvantages. It limits specialist care to what is "necessary"; and it results in the family doctor's getting a thorough knowledge of his patients in the course of time, not only of their state of health but also of their social conditions, their milieu—knowledge of great medical importance which cannot easily be concentrated in one person if the service is not organized on the family doctor principle.

In contrast to the family doctor scheme is the medical care service, which does not attach importance to the establishment of a regular relationship between families and general practitioners, and which permits of free choice of doctor for each new case of illness and consultation with a specialist without reference to a general practitioner. Such a service does not make a point of limiting specialist care to what is "necessary"—i.e., to the difficult cases for which a non-specialist dare not be responsible. The result is that specialist care is given more frequently. This may at first sight appear an advantage. The fact that some cases will be treated by a specialist even when it is unnecessary may not change this view; nor

may the fact that some cases, although applying to a specialist, will not really be treated by one, for the same patient may have symptoms, and suffer from illnesses, coming under different specialties, and for practical reasons a corresponding number of specialists will not always be available to the patient.

The conclusive objection to such a service, however, is that the thorough knowledge of patient, family, and milieu, which in the family doctor scheme is concentrated in the regular doctor of the family, cannot be gathered by one person if the family doctor scheme is abandoned. Reports from hospitals and other health units, tuberculosis centres, medical laboratories, x-ray clinics, specialists, etc., which are now all collected in the family doctor's file, and which together with the family doctor's own observations constitute, when co-ordinated, immensely valuable material for judging the state of health of each patient, would be scattered to the four winds of heaven.

This is, in a nutshell, the supreme merit of the family doctor scheme, and it far exceeds anything that may be advanced in favour of its rival. At the same time I should like to point out that the family doctor scheme is the more rational, not only from a medical but also from an economic point of view. The education of the specialist is normally more prolonged than that of the general practitioner, and it is more difficult; in fact it cannot be obtained without a considerable contribution on the part of the doctor. So it is only reasonable that the services of the specialist should be more expensive than those of the general practitioner and that they should be employed only where "necessary."

#### Sickness Benefit Clubs

The sickness insurance of persons of small means is based upon voluntary membership of approved subsidized sickness benefit clubs. The total income of these clubs was in 1942 about Kr.107 million, about Kr.70 million of this being contributions and Kr.23.6 million State subsidies. The income limit for membership of sickness benefit clubs is at present Kr.6400 in Copenhagen, Kr.5700 in the provincial towns, and Kr.4700 in the country. The limit is based upon the taxable income. Children under the age of 15 years are insured in virtue of the contributions paid by their parents.

The benefits of the clubs are partly compulsory (provided by law): free medical care (not including specialist care, however), free hospital treatment, daily allowances according to special rules (up to Kr.6 a day against payment of a corresponding extra contribution), and free midwife and medical assistance on confinement. Other benefits are voluntary (to be fixed in the rules of the sickness benefit club): for instance, specialist care and medicine, dental care, nursing at home, etc. The voluntary benefits are often granted to a too small extent or not at all.

The payment of the sickness benefit clubs for general-practitioner care is made according to an agreement between the organizations of the clubs and the doctors. In all towns a fixed amount is paid per year per member, at present Kr.9.30 per member over the age of 15, nothing for children under that age. Married couples are considered as two members. The rates are now to be increased by about 50%. In the country the doctors are paid for services rendered—for instance, per consultation Kr.3.35, journeys up to 2 km. Kr.6, plus Kr.0.70 for each additional kilometre begun. Conveyance allowance is granted in the rural districts. Additional rates are allowed for special examinations and various surgical operations. The cost of medical care per member per year is somewhat higher in the sickness benefit clubs paying for services rendered than in those paying a fixed amount per year, at present on an average Kr.13 to Kr.14.

Patients have free choice of doctor. In Copenhagen the number of doctors participating in the sickness benefit club service is by contract limited to one doctor for 1,500 members. However, the proportion at present is 1 to 1,700. Outside Copenhagen the doctors' right to participate in the service is not limited; in the country, however, it is subject to the provision that the members must choose their doctor within a distance of 10 km. if practicable. The average number of members per doctor is somewhat lower in the country than in Copenhagen (about 1 to 1,200 to 1,300).

Practices may be bought and sold everywhere except in Copenhagen. The price of a practice amounts to approximately the gross income of one year.

#### Two Types of Club

We distinguish between class I sickness benefit clubs, which pay the doctors a fixed amount per year per member, and class II sickness benefit clubs, which pay for services rendered. In all class I clubs and in some class II clubs the members have to choose their doctor for a calendar year at a time, according to the agreement between sickness benefit clubs and doctors. A married couple must have the same doctor, and he then becomes the doctor for all the children too. It is the family doctor principle with the regular doctor-patient relationship that is operative here. It may be added that the relationship is not so regular that it cannot be broken in case of disagreement between doctor and patient. In some class II clubs, however, the members are entitled to change their doctor during the year. Few people avail themselves of this right, partly because these clubs are situated in country areas where the possibility of changing to a new doctor is small.

The method of payment of class I is that generally used in club practice, and in recent years it has had an ever-increasing extension at the expense of that of class II. It implies, too, the regular relationship between the insured persons and their doctor. It cannot be denied that the fixed annual amount is more closely related to the "family doctor fee" formerly much used in private practice. Nor can it be denied that the family doctor is more independent in his work when he is under no obligation to account for the number and nature of his services.

#### "Compulsory Reference" by General Practitioners

It is one of the most important assumptions of the family doctor scheme that specialist care can only be given through the sickness benefit club when the patient is referred by the general practitioner. This "compulsory reference" has been framed by sickness benefit clubs, general practitioners, and specialists in agreement. I am convinced that the sickness benefit clubs have realized the many advantages of the family doctor scheme, but it would not be unreasonable if economic factors had made themselves strongly felt. Specialist care is more expensive than general-practitioner care, and the clubs have wanted to grant only "necessary" specialist care, and have left the decision to the general practitioners.

This agreement between the three negotiating parties—sickness benefit clubs, specialists, and general practitioners—has in Denmark afforded a very firm basis for the family doctor scheme. In this connexion it has been a great help that the Danish sickness insurance from the start was planned as a family insurance automatically including children under the age of 15 years, and it has always been independent of whether or not the beneficiary was a wage-earner in a special employment. Insurance services in other countries did not permit of voluntary insurance of children and members of the family who were not wage-earners until much later. The balance of the Danish family doctor scheme has made it more viable. It has among other things involved the organization by central and local bodies of preventive tasks based on the family doctor scheme, in the first place assigning diphtheria vaccination to the general practitioners, later on general health care of expectant mothers, and now general health care of children from 0 to 7 years. In most other places these tasks are assigned to doctors and institutions specially appointed and set up for the purpose.

#### Regulations Governing Specialists

Besides the agreements between sickness benefit clubs and doctors the family doctor scheme has been consolidated by certain provisions in the collegiate rules of the Medical Association. Thus a doctor having a certificate of competence for a specialty and wanting to furnish specialist service is not allowed to render general-practitioner care. We have been aiming at a clear definition of general practitioners and specialists because we wanted organized collaboration on the family doctor principle. The provision does not apply to private patients, but they are treated less consistently on this principle than the club patients and must consequently put up with the draw-

backs of not having a regular doctor. In the Medical Association's rules is a provision to the effect that a specialist, when a patient is referred to him in writing, shall directly inform the referring doctor of the result of examination and treatment; he must not refer the patient to other doctors without the consent of the referring doctor; and he must leave the further treatment of the patient to the referring doctor as soon as the specialist treatment is finished.

It is hardly an exaggeration to say that the family doctor scheme has been carried through more consistently in Denmark than in most other places. This is partly due to the fact that the sickness benefit clubs have adopted this scheme and have given it a dominating position by their growth. It is also due to the fact that Denmark is well provided with general practitioners who have received a good and uniform education. The specialization of medical science has of course led to an adaptation of the family doctor scheme to the requirements of the age. Here we have been faced with the same problems which Great Britain is now trying to solve through organization.

### Problems of a Health Service

1. *General practitioners must have sufficient time for their work and for continued studies.* It must be admitted that it has been somewhat difficult to attract the attention of the sickness benefit clubs to this requirement. The principal method of payment is, as mentioned, a fixed amount per year per member. This amount has hitherto been very small; with the present price level it is Kr.9.30 per member per year, any person over the age of 15 being regarded as one member, and children under 15 being covered by the breadwinner without additional fee. This has resulted in an expansion of practices to a higher level than desirable. The work itself has made greater demands—of quality as well as quantity—and the patients as well as the doctors have every reason to regret that generally the doctors have not the necessary time for their work.

However, some understanding of this state of affairs on the part of the sickness benefit clubs is now perceptible; recently it has been possible to carry on discussions on the basis that a practice of average size—i.e., about 1,500 patients—should yield a reasonable net income, which it has not done so far. At the same time the parties have agreed about appropriate measures to prevent excessive enlargement of practices. That means one step nearer the aim of sufficient time; and it will be possible to continue this development so far as the number of available doctors allows.

2. *Up-to-date laboratory services should be available to the general practitioners.* We are on the point of having solved this question in a way satisfactory to the doctors as well as to the population. As early as 1922 the general practitioners in Copenhagen established their own central laboratory, which since then has developed into a large institution rendering the general practitioners all the technical assistance they need for examinations. Doctors may send material for examination, or they may send their patients to the laboratory for investigation of metabolism, for electrocardiography, test meals, etc., and for production of material for examination (blood tests and the like), where this is best done at the laboratory.

The laboratory is operating to the complete satisfaction of everyone. At the outset we had a central laboratory with branches, but we found that the distances in Copenhagen (scarcely 1 million inhabitants) made it unnecessary, for the central laboratory in fact was situated in the centre. Outside the capital the numerous public hospitals are operating as laboratories for the doctors in a similar way.

The technical assistance rendered to the general practitioners by the laboratory seems in England to be one of the arguments for group practice. In Denmark we did not feel tempted to change over to this form of practice because we know from experience that a really efficient laboratory cannot nearly be utilized to its capacity by the ten doctors supposed to constitute a group; and a laboratory which is not quite efficient can hardly be adequate.

3. *X-ray services should be available to the general practitioners.* In Copenhagen the sickness benefit clubs pay for x-ray examinations on patients referred by general practitioners to the many private x-ray clinics, most of which are fully efficient. Outside the capital x-ray examinations are under-

taken at the public hospitals, which are situated within easy distance even of the country population. It seems as if in England this question is to be solved by health centres equipped with x-ray services, but in view of the above it will be understood that we have been under no temptation to try this solution. Here the same thing may be said to apply: ten doctors cannot nearly utilize a really efficient x-ray clinic to its capacity; and a clinic that is not fully efficient does not solve the problem.

4. *Clinical assistance by specialists, for examination as well as treatment; should be available to the general practitioners.* In this field the Danish National Health Service is still insufficient. This is due partly to the fact that we have not got the desirable number of specialists all over the country, partly to the fact that the sickness benefit clubs have been too reluctant to pay for the necessary specialist care, having to grant only free general-practitioner care under the Act. The sickness benefit clubs have shifted the expense of specialist care on to the public hospital service, apart from specialist care for eye diseases and diseases of ear, nose, and throat. For these specialties there is an ample number of specialists all over the country; and the sickness benefit clubs have an agreement with them according to which the members receive free specialist care when referred for such treatment by their family doctor.

So far as I can see, another argument for group practice is that it is easier to collaborate with specialists attached to the group. If the non-specialists of the group are to make a contribution themselves, however, ten doctors will not be able to utilize the specialists to their capacity. Ten doctors may utilize an eye specialist and an ear, nose, and throat specialist provided that they refer every case of illness within these specialties. As regards the other specialties it will not be possible according to Danish experience. All the talk about group practice in England has not failed to stir some mind in the small country over the North Sea; but outside the few who are always excited about anything that is brand new the idea has not met with enthusiasm.

### Specialist Diagnosis for Out-patients

As regards the other specialties the doctors often have to send their patients to hospitals in order to have them examined and treated by specialists. Since in many cases this is done merely because the doctor, in spite of laboratory and x-ray facilities cannot solve a diagnostic problem, the hospital service has considered allowing the hospital specialists to make the diagnosis and advise out-patient care so as to avoid the expense of hospital admissions. Only in the capital may the general practitioners to some extent be in consultative collaboration with the practising specialists.

The medical profession would prefer a further development and extension of this scheme, for we have some hesitation in contributing to the increase of out-patient departments by attaching specialist care to the hospitals. Even if the specialist care supposed to be afforded by hospitals in the form of out-patient service is meant merely to help doctors to make the diagnosis (after which the treatment is referred to the general practitioners), diagnosis often involves therapy; and then you are well on the way to the out-patient clinic or health centre. This development is hastened by the fact that some forms of treatment require hospital equipment and other auxiliary services, and are therefore already undertaken at the hospital in the form of out-patient care. Apart from specialist care requiring the auxiliary services of the hospital, we want this care to be given by practising specialists, because in that way one can be sure that the patient is in fact treated by a specialist. The large out-patient departments will always have a considerable staff of young doctors completing their training. They very often have to work rather independently without the clinic's specially trained doctors' being able to supervise the work of each person. So it is somewhat problematic—as circumstances are in Denmark at least—to talk about specialist care in connexion with out-patient care. For that reason and because we are of opinion that the work of the specialist as well as that of the general practitioner in most cases is done best in private we have so far as possible tried to avoid a development of actual out-patient departments—and with success in so far as there are out-patient departments in the capital only. The

are few, however, and in the form of closed departments which do not receive patients who have not been referred by their doctor. As the sickness benefit clubs in the capital are now more than willing to grant specialist care by practising specialists, it seems possible to have all specialist care (apart from that requiring hospital treatment) assigned to the practising specialists. It is to be hoped that a corresponding development will prove possible outside the capital.

Having a developed family doctor scheme—an organized collaboration between the general practitioners and the medical laboratories, the x-ray clinics, the practising specialists, and the hospitals. We consider this arrangement sound. Even if the system is far from being perfect in various points, we are under no temptation to change it. Nor do we feel any great pressure from the public or the politicians, though I dare say we are prepared for it. It is a consequence, I suppose, of our not being so anxious to "socialize" the doctors, which may be explained by the fact that Danish doctors have been subject to a gentle process of socialization over several years by their relation to the sickness benefit clubs. The final result has been that "few have too much and fewer too little."

Under these circumstances it has even been possible to plan a pension scheme for the Danish medical profession, a scheme which is now ready for implementation. It rests upon provisions in the agreements between the public hospital service and the hospital doctors and between the sickness benefit clubs and the doctors participating in the service, according to which pension contributions are paid by the hospital service and the sickness benefit clubs into the "Pension Fund of the Medical Association," which together with a financial body administers the subscriptions and the payment of old age and invalidity pensions. Being incorporated in these agreements, the scheme is compulsory for all the doctors covered by them—i.e., the great majority of Danish doctors.

It is evident that the problems involved in the organization of medical care differ in Britain and Denmark, but even so this account may be of interest to doctors in England. The ends aimed at in Britain—time for the doctors, technical assistance, clinical assistance by specialists, in brief, an effective medical scheme—may also be gained through the channels followed in Denmark without changing the form of practice from individual to group practice and without making a civil servant of the doctor, provided that a sufficient number of doctors is available. It does not matter then whether the sickness benefit club or the State is the doctor's employer.

### RADIO-ACTIVE SUBSTANCES BILL

This Bill was recently discussed in the House of Lords (May 24, p. 747). Clause 5 prevents the use for therapeutic purposes of apparatus which produces radiation except under licence of the Minister of Health. The British Medical Association is advised that this would cover radio-active substances, deep x-ray therapy, short-wave therapy, ultra-violet and even radiant heat lamps. This restriction does not relate to the use of such apparatus for medical, surgical, or dental diagnosis, but it strikes a blow at the principle that once on the *Register* a practitioner should not be prevented by law from treating patients by any method without restriction.

In 1945 the Association appointed a special committee to consider this problem. That committee recommended to the Ministry that the use of radio-active substances should be restricted for an experimental period of, say, two years, after which these substances should be available, as other therapeutic substances are, to all registered medical practitioners. In brief, the restriction should operate only during an experimental period to enable adequate knowledge to be gained of the dangers and necessary protective measures. Representations are being made to this effect.

### RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Dr. M. P. Leahy, at 39, Harley Street, W.1 (Langham 4012); Mr. Harold Park, F.R.C.S., at 40, Wilbury Road, Hove, 3, Sussex; Dr. James S. Young, M.R.C.O.G., at 37, Harley Street, W.1 (Langham 3556).

## HEARD AT HEADQUARTERS

### Anonymity on the Air

About thirteen years ago the General Medical Council expressed the view that registered medical practitioners "should broadcast anonymously." The phrasing is a little ambiguous, but the meaning was that if registered medical practitioners felt compelled to take to the air they should not have their names announced. The appearance of television has reopened the question. May a medical practitioner allow his lineaments to be revealed on the television screen? Suppose by some extraordinary development that all broadcasting were accompanied by television, is a medical practitioner on facing the microphone plus the television camera to wear a mask or to have a coat dropped over his head like a criminal under public arrest? People naturally like to know who is talking to them, and the same applies in broadcasting. The Central Ethical Committee of the Association some time ago discussed this question and presented to the General Medical Council a considered case for permitting practitioners, when giving broadcast talks on medical subjects, to appear in television and to be announced by name. But two committees of the General Medical Council have now shaken their heads over the proposition and see no reason to modify the opinion expressed in 1934. Advertising by any professional man, of course, is to be deplored, but apparently other professions do not carry the embargo to this extent. It does seem a little anomalous when a Brains Trust or other debating team is on the wireless to have men in other professions duly announced while the medical representative, if there is one, is referred to mysteriously as a well-known physician (or surgeon, or psychiatrist, as the case may be). At one and the same time it gives the anonymous individual an undue importance and casts a slight slur upon him.

### The Scottish House

It is interesting to learn that the Scottish Committee is considering an appropriate commemoration of the officers and officials, past and present, of the Association in Scotland in the Scottish House in Edinburgh. Scotland has produced some great leaders, several distinguished Presidents, and a number of men who have made their mark at Headquarters in London, including the present Chairman of the Representative Body. Dr. Craig's long and able Scottish secretaryship, which has lately ended, should have some outward and visible reminder in the place where he worked. The Scottish House of the Association was opened at almost the same time as the Tavistock Square premises in London. No. 6, Drumshugh Gardens was first taken, and then, two years later, No. 7, and the two houses were turned into one at the first floor so as to provide an excellent conference room for 300 people. It is in this room that it would be interesting to have panels with the names of those who have served the Association in various official capacities north of the Tweed.

### The G.M.C. Bill

The draft Medical Bill for a procedure reformed in many respects has passed through its final stage of approbation by the General Medical Council. There have been conferences between the B.M.A. committee and the Defence Societies on the one hand and the Legislation Committee of the G.M.C. on the other. Some of the points which the outsiders suggested have been accepted, and others have not been pressed because of the desirability of getting an agreed Bill if possible. Any considerable divergence of view would have spoiled the Bill's chances of success. The points incorporated in the Bill are mostly small but useful ones, as, for example, the requirement that if an appeal is lodged by a practitioner against the direction to erase his name the direction shall be suspended until the appeal is determined. Justice has, in the main, at least of late years, always been done by the G.M.C., but the new measure will help to ensure not only that justice is done but that justice appears to have been done.

## Correspondence

### Evidence for Spens Committee

SIR,—I am given to understand that the B.M.A. has lent its services in the form of the use of its address, and part of its secretariat, to further a wholly pernicious inquiry for the latest Spens "Gestapo committee." I must protest strongly against the terms of the document issued by this Evidence Committee. It would appear that the B.M.A. is rapidly descending the slippery slope towards becoming a collecting house for evidence for the enslavement of the profession.

Why should it be necessary to set a "ceiling" to the earnings of any person in a free service? Does not the profession realize that all the codification, classification, and Nazification in this and other documents can only lead to enslavement of the profession and populace? When are we as an Association going to realize the gravity of the situation whose coming we are assisting by these questionnaires, etc.? It is to be hoped that consultants will have nothing to do with this, and they will not be led by the usual timid *vis a tergo* of our so-called leaders.

There are still many doctors sufficiently alive to the dangers of National Socialism to deprecate the all too apparent eagerness of the Association to co-operate with the Government in the establishment of a bridge-head of the full-time salaried State service. The circular letter to consultants certainly did not make it clear that this information was sought solely for the benefit of whole-time servants of the State. It is high time that the mechanism of the Association was brought to bear wholeheartedly on protecting the independence of independent practitioners, by whom, and presumably for whom, the Association was founded.

Let us have a bold lead and less of the Duke of Plaza Toro and a little more resistance to encroachment on liberty.—I am, etc.,

London, W.1

DAVID HALER.

\*\* The Secretary of the B.M.A. comments: The new Spens Committee is concerned only with the range of remuneration of consultants and specialists engaged in a public service on a full-time basis, and not undertaking private practice. The Committee has been instructed to pay due regard to the financial expectations of consultants and specialists in the past; it must therefore obtain reliable information. The previous Evidence Committee carried out a similar inquiry to the satisfaction of general practitioners. The word "ceiling" does not imply that a practitioner will be unable to earn more than that figure.

### Regional Hospital Boards: Salaries

SIR,—We are informed (*Supplement*, June 7, p. 116) that the Minister of Health proposes to offer salaries of between £2,000 and £2,500 for the appointments of chief administrative medical officers of the fourteen hospital boards. It is to be hoped that the Association will oppose these salaries, even to the extent of black-listing the posts if necessary. These fourteen appointments will be among the very highest in the field of medical administration. In other professions a man who reaches the top of the tree does not rest content with £2,500. Are these fourteen men who will administer the nation's hospitals to be considered of less value to the community than are judges? A judge receives £5,000 a year. The Association recently drew up a suggested scale of salaries for medical officers of health and other full-time salaried officers. On this suggested scale the M.O.H. of a large county or city would earn £3,000. The whole scale would be thrown out of focus if the administrative medical officer of a regional hospital board received only £2,500.

Although clinicians and administrators sometimes make the mistake of disparaging each other, the general public is—not unwisely—more and more tending to equate the two, to think that the doctor who specializes in paediatrics or neurology is worth about the same as the doctor who specializes in hygiene or administration. Consequently, if these low salaries are offered to the leading specialists in administration, we can expect sooner or later that similar salaries will be offered to

outstanding clinicians. Are the chief administrative officers of the National Coal Board paid as little as £2,500 per annum? If not, why should the medical administrator receive less than the administrator in other fields?—I am, etc.,

A MEDICAL ADMINISTRATOR.

## Association Notices

### Nathaniel Bishop Harman Prize

The Council of the British Medical Association is prepared to consider a first award of the Nathaniel Bishop Harman Prize in the year 1948. The value of the prize is approximately £100.

The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has previously been published in the medical Press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1948 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

The writer of the essay to whom the prize is awarded may be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

Essays must be forwarded to reach the Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual Meeting of the Association to be held in 1948. Inquiries relative to the prize should be addressed to the Secretary.

CHARLES HILL.

Secretary.

### Diary of Central Meetings

JULY

- 22. Tues. Council, 11 a.m.  
Annual Representative Meeting, 2 p.m.
- 23. Wed. Annual Representative Meeting, 10 a.m.  
Annual General Meeting, 12.30 p.m.
- 24. Thurs. Annual Representative Meeting, 10 a.m.

### Branch and Division Meetings to be Held

EAST HERTS DIVISION.—Wednesday, July 9, 2.30 p.m. Visit to Messrs. Allen and Hanbury's factory at Ware.

LANCASHIRE AND CHESHIRE BRANCH.—At Chester Town Hall Thursday, July 10, 2.30 p.m. Annual meeting. Election of Officers etc.

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, W.C.1, Tuesday, July 8, 2.30 p.m. Eighty-ninth Annual General Meeting. Agenda: Report of Branch Council for the year 1946-7; report of Branch representatives on Central Council 1946-7; report as to elections of officers for 1947-8; address by incoming President.

SHROPSHIRE AND MID-WALES BRANCH.—At Eye, Ear, and Throat Hospital, Shrewsbury, Tuesday, July 8, 3.15 p.m. Clinical meeting Mr. S. W. G. Hargrove: "Hoarseness."

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.—At Herefordshire General Hospital, Hereford, Thursday, July 10, 2.30 p.m. Annual meeting.

### TRADE UNION MEMBERSHIP

The following amendment is made to the list of "closed shop" authorities:

County Borough Councils: Add Barnsley.

Non-County Borough Councils: Delete Barking.

LONDON SATURDAY JULY 12 1947

## CHOICE OF DRUGS IN THE TREATMENT OF DUODENAL ULCER\*

BY

A. H. DOUTHWAITE, M.D., F.R.C.P.

Physician to Guy's Hospital

much has been written during the last quarter of a century on the dietetic control of duodenal ulceration, whereas the rational use of drugs has been to a great extent ignored. It is on the latter therapeutic measure that I present the following observations.

## Belladonna

The use of belladonna in the treatment of duodenal ulcer has been practised widely for 25 years. Experiments on animals, and later on human beings, led to the belief that the drug caused a considerable reduction in acid output by virtue of a paralysing action on the vagal nerve-endings. Thus Bennett (1922) emphasized the value in this respect of washing the stomach with a dilute solution of atropine before meals. It soon became standard practice to give belladonna or atropine, usually 5 minims (3 ml.) of tincture of belladonna before alternate two-hourly feeds (Ryle, 1923) and 1/100 gr. (0.65 mg.) of atropine sulphate hypodermically at night. Ryle stated that belladonna given in this way would cause dry mouth, laxation of the pylorus and thus reflux of duodenal contents, and modification of the gastric acidity more than that produced by alkali. Schick (1910) declared that its chief value lay in overcoming pylorospasm, and Crohn (1918) refers to the transient and poor effects of atropine on gastric acidity.

No serious criticism of the use of belladonna as an acid pressant arose until in 1938 Davidson and Nicol communicated to a meeting of the Gastro-Enterological Club the results of experiments which showed that even toxic doses of atropine had no constant or marked influence on gastric acidity. Later Nicol (1939) published a paper reiterating that atropine failed to influence gastric secretion and that its value lay in its antispasmodic action.

If belladonna has in fact any action in reducing gastric secretion it can only be by virtue of its paralysing the vagal terminations. It follows, therefore, that only reflex secretion would be abolished, whereas the more important and lasting humoral secretion would be untouched. On theoretical grounds one would expect some diminution in acid output to be produced by belladonna, the degree of change being influenced by the character of the food—appetizing or monotonous—the personality of the subject, and the period of time following ingestion of food. It would be inconceivable that a therapeutically effective reduction of acidity could be produced by belladonna in any dosage.

In order to confirm Nicol's work I investigated the effect of *l*-hyoscyamine on the test-meal curves of 25 patients with hyperchlorhydria and duodenal ulcer. It will be

remembered that the action of belladonna is largely due to atropine, and that atropine is racemic hyoscyamine. Furthermore, the peripheral effect of atropine is almost entirely due to its *l*-hyoscyamine component. As it is this action which concerns us, and as the

central stimulant effect of both *d*- and *l*-hyoscyamine is unwanted, the latter drug was clearly one of choice. Hyoscyamine sulphate, 1/80 gr. (0.8 mg.), was given by mouth night and morning for three days. On the fourth day, an hour after the morning dose had been taken, the test-meal was given. It will be appreciated that this is high dosage, equivalent in alkaloid value to 36 min. (2.1 ml.) of tr. belladonnae per dose. Within 36 hours it produced persistent dryness of the mouth, thirst, and dilatation of the pupils. Duodenal ulcer pain, if previously present, disappeared as soon as these signs were manifest, yet it will be seen from Figs. 1a, 1b, 2a, and 2b that the effect on acidity was so slight that it is highly improbable that it would have influenced the pain. Although in a few instances the depression of acidity was more than that shown in these graphs, in no case was it great or prolonged.

If, then, it be agreed that the effect of belladonna on gastric acidity can be disregarded, why is it that it does

FIG. 1a.—Case of duodenal ulcer. Curve of free HCl during gruel test-meal.

FIG. 1b.—Curve from same patient as Fig. 1a taking hyoscyamine.

FIG. 2a.—Further case of duodenal ulcer. Gruel test-meal.

FIG. 2b.—The same as Fig. 2a during hyoscyamine treatment.

\* Based on a communication to the Brighton and Sussex Medical-Surgical Society on April 3.

in fact relieve pain? Of such action there can be no question provided that adequate quantities be given. No benefit is derived from belladonna unless persistent dryness of the mouth is produced by it. The customary dosage is therefore useless. In practice it will be found that 30 min. (1.8 ml.) of the tincture of belladonna, 1/100 gr. (0.65 mg.) of atropine sulphate, or 22 min. (1.3 ml.) of liquid extract of hyoscyamus given four-hourly will be effective. Yet more efficacious is 1/120 gr. (0.54 mg.) of *l*-hyoscyamine twice daily (Douthwaite, 1939).

It is well known that the belladonna alkaloids have a pronounced effect on the motility of the gastro-intestinal tract, especially in the direction of quelling abnormal contractions. It is also usual to note excessive gastric peristalsis, often combined with pyloric spasm, in patients suffering from duodenal ulcer. Furthermore, rapid emptying of the stomach is common not only during the active phase but also during periods when healing of the ulcer seems to be established. Numerous observers have noted how this hypermotility is abolished by full doses of atropine. It can be demonstrated radiographically, and was noted by Wolf and Wolff (1943) in their experiments on a patient (Tom) with a gastric fistula. They showed, furthermore, that atropine resulted in a great prolongation of emptying time.

If it can be accepted that the pain of duodenal ulcer is due to abnormal contractions of muscle fibres in the stomach or duodenum, or both, the benefit conferred by belladonna can be understood. There are two schools of thought in regard to the pain-producing factor: the one favouring muscular contractions and increased tonus, resting on the observations of Bolton (1928), Christensen (1931), Hurst (1911), Ryle (1926), and Poulton (1928); the other stressing the importance of acidity, based on the work of Palmer (1926), and recently of Bonney and Pickering (1946). The evidence derived from careful clinical experiments by the latter school certainly presents convincing grounds for the belief that a certain level of acidity, varying from case to case, will, if reached, be directly responsible for ulcer pain. This does not, however, exclude the possibility that the muscular contractions may also cause pain or, in fact, may be the usual excitant of pain production. An argument often put forward is that if an intragastric balloon fails to record a rise of tension coincident with pain, increased muscular tonus cannot be incriminated. Such a conclusion is not justified. Only if an increase of gastric tonus as a whole should occur would one expect it to be registrable manometrically. Localized spasm could not possibly influence the tension within the balloon, yet it might well give rise to pain.

The "acid hypothesis" fails to explain certain common features of pain in uncomplicated duodenal ulcer—namely:

- (1) Its occurrence at 2–3 a.m. and its spontaneous subsidence even if no food or alkali is taken. The chart of gastric acidity (Fig. 3) taken during sleep shows it to be lower at 2 a.m., which was the hour when pain usually awakened this patient.
- (2) Its spontaneous subsidence before meals if the meal is postponed.
- (3) Its lessening or disappearance within half an hour of lying down.
- (4) Its relief from the application of heat to the abdomen. This is known to inhibit gastric

FIG. 3.—Duodenal ulcer. Free HCl curve during night. Samples removed hourly.

and intestinal peristalsis (Bisgard *et al.*, 1942). (5) Its rapid relief by  $\text{CO}_2$ —producing antacids, whose effect on acidity is transient as compared with the non-gas-producing antacids such as trisilicate. (6) The invariable relief afforded by full doses of belladonna alkaloids.

It is reasonable also to assume that the pain of gastric and duodenal ulcer has the same mechanism of production; yet in the former case gastric acidity is usually within normal limits and there may, in fact, be no free hydrochloric acid throughout digestion.

FIG. 4.—Chronic duodenal ulcer. Note hypertonicity and pronounced peristalsis after four weeks' milk-drip.

FIG. 5.—The same as Fig. 4, one day later, an hour after hyoscyamine sulphate, gr. 1/80 (0.8 mg.).

Finally, a positive argument in favour of the muscular tension theory is afforded by radiographic observations. The radiographs (Figs. 4 and 5) of the stomach of a sufferer from duodenal ulcer were obtained within 24 hours of each other. Continuous pain was being experienced while

taking Fig. 4, in which a series of peristaltic waves are seen. In Fig. 5 gastric tone and motility are strikingly lessened as the result of 1/80 gr. (0.8 mg.) of hyoscyamine sulphate. The patient was entirely free from pain. Numerous observations have shown the same sequence of events. It follows from this that the operation of vagotomy for duodenal ulcer is wholly unjustifiable. Belladonna can achieve all the good results claimed for such surgery without the danger and permanent mutilation it entails. It is probable that two factors produce pain in peptic ulcer—abnormal muscular contractions, and a chemical stimulus provided by hydrochloric acid. The justification for the use of belladonna is thus established. We have now to consider the control of acidity.

### Antacids

No matter what views are held on the mechanism of peptic ulcer pain production, it is common ground that free hydrochloric acid is of great importance in preventing the healing of the ulcer. It is reasonable, therefore, to seek to neutralize this acid so long as an ulcer is present. Once healing has been secured the need is far less, if indeed it exists at all. It should be noted here that Ryle and Bennett (1937), from a follow-up of 100 students subjected to test-meal analysis in 1921, concluded that there was no association between degrees of gastric acidity and the development of dyspeptic troubles.

In point of fact all the drugs commonly used to neutralize gastric hydrochloric acid have such a transient action as to be valueless. The fleeting action of sodium bicarbonate, calcium and magnesium carbonate, and tribasic phosphates is too well known to require further emphasis. Experiments carried out by E. B. French and myself on patients with peptic ulcer (Douthwaite, 1939) showed, furthermore, that aluminium hydroxide gel and magnesium trisilicate when given hourly failed to neutralize hydrochloric acid for more than a quarter of an hour. The former when given by continuous drip, 1 oz. (28 ml.) hourly, was likewise ineffective. Figs. 6a, 6b, and 6c illustrate the short action of these substances. It is true

One of the reasons for the transience of antacid action in cases of duodenal ulcer is that the stomach empties so quickly. The same conclusion was reached by Nicol (1939) in respect of the fact that hourly feeds of milk fail to produce neutralization.

He also showed that neither hourly nor two-hourly feeds of milk foods, vegetable purée, eggs, and fish, in conjunction with carbonates, would cause lasting depression of gastric acidity; in fact, two-hourly feeds containing more protein are more effective than hourly milk meals.

The only satisfactory way to neutralize gastric hydrochloric acid for days on end is to give milk by drip-feed through a Ryle's tube passed into the stomach. Five pints (2.84 l.) given in 24 hours may be completely effective, as is shown in Figs. 7a, 7b, and 7c. The patient is seldom intolerant of this treatment, especially if the tube be passed through the nose. It is withdrawn and cleaned twice a week, and the drip can be discontinued at the end of three to four weeks. When such treatment is impracticable the next-best measure is to give 1/2 oz. (14 ml.) of olive oil (this delays emptying and reduces acid output) and 1/2 oz. (15.5 g.) of magnesium trisilicate in 8 oz. (227 ml.) of milk two-hourly, between two-hourly main feeds. These should consist of porridge, egg, milky foods, bread-and-butter, fruit juices, purée of fruit and vegetable, fish, and chicken. In fact, if chemical irritants—for example, mustard, spices, vinegar, and alcohol—are avoided and if other food is free from gross roughage, all the common foods may be safely taken from the beginning of treatment. If a milk-drip is used, then three meals a day may be given in addition to the milk.

FIG. 7a.—Duodenal ulcer. Gruel test-meal (1/4-hour samples).

FIG. 7b.—Same case as 7a. Continuous milk-drip, 5 pints (2.84 l.) in 24 hours for eight days; thereafter in daytime only. First rise of acidity due to interruption of drip. The later rises coincided with nights when the drip was suspended.

FIG. 7c.—Shows the feeble antacid effect of 5 oz. (142 ml.) of milk given hourly.

FIG. 6a.

that in a long series one meets with instances in which one or other of the antacids appears to have a prolonged action, but it is the effect on the majority which is of importance.

### Anxiety

After considering hypermotility and hyperacidity, our third and last problem is the control of anxiety, the effects of which are inimical to healing. This has already been done in part by blocking vagal impulses with hyoscyamine. The choice of a suitable cerebral sedative is not a matter of great difficulty. Phenobarbitone answers the purpose in the majority of cases. It may, however, prove unsuitable by causing skin rashes, fever, giddiness, and incoordination. More commonly it produces intense depression of spirits and disinclination to co-operate in the full treatment of peptic ulcer. Yet again, it may

completely fail to relieve anxiety and restlessness unless given in excessive doses. If 1 gr. (65 mg.) thrice daily fails to produce the desired effect it is wiser to change the drug than to increase the dosage. It should be borne in mind that phenobarbitone is an indifferent hypnotic, and that at night it is usually necessary to give a more potent soporific—for example, "sodium amytal," 3 gr. (0.2 g.).

When phenobarbitone fails a state of mental and muscular relaxation can be achieved by the use of cannabis indica. This drug has fallen into undeserved disrepute because of the danger of addiction, and even more because its preparations are often inert. The former risk is very slight when cannabis is used therapeutically for a limited period. It is certainly far less than that entailed by the use of opium and its derivatives. Taken by a patient resting in bed, and thus removed from any suggestion of conviviality, it produces a languorous state and sense of well-being, without the flights of imagination for which it is taken by the addict. Furthermore, it does not cause constipation, and the appetite is unimpaired. In fact, it may lend enchantment to the dietary.

Extractum cannabis (*B.P.C.*) is the preparation of choice; the tincture has a most unpleasant taste, and its resin is precipitated by the addition of water. The recommended dose of 1 gr. (65 mg.) is too small to be effective. Four times this amount should be given in capsules four times daily. The frequency of administration is adjusted to the result. It will allow of continuous drip-feeding in patients who would otherwise be intolerant of it. It is seldom necessary to give the drug for longer than two weeks, and a supply should never be left in the patient's charge. I have used the physiologically tested extract and have found it to be active, but it is as well to procure only a small stock at a time and to keep it at a low temperature—10° C. The effectiveness of the drug in inducing, presumably by central action, relaxation of the stomach is well illustrated by Figs. 8a and 8b. Symptomatically this patient suffered

FIG. 8a.—Chronic duodenal ulcer with clinical signs of stenosis. This is masked in the radiograph because of powerful peristalsis.

from pyloric obstruction, yet the emptying rate, determined radiologically, was rapid. The second radiograph (Fig. 8b), taken after treatment with cannabis at the same time, after a barium meal, shows that the rapid emptying was the result of hyperperistalsis and that true obstruction was present. This was confirmed at operation.

FIG. 8b.—Same case as 8a when taking 4 gr. (114 ml.) of ext. cannabis four times daily. Stomach relaxed; stenosis revealed.

### Harmful Drugs

In conclusion a brief reference to chemical substances which may aggravate symptoms of ulcer should be made.

**Tobacco.**—Experimental evidence favours harmlessness smoking to patients with chronic ulcer. Neither rate of emptying of the stomach nor acidity can be shown to be appreciably affected. As against this it is a spontaneous observation, countless sufferers from duodenal ulcer that the pain, in the active phase of the disease, will always be produced or, present, aggravated by the smoking of a single cigarette. Again on inquiring into change of habits preceding a relapse, he often does one find that the only prophylactic measure which has lapsed has been abstinence from tobacco. It may well be that direct irritation of the gastric and duodenal mucosa is set up by pyridine, furfural, and acrolein, which are present in tobacco smoke and which are swallowed in saliva. I have no doubt that smoking should be limited—a pipe after breakfast and another after dinner—throughout the life of the patient.

**Mustard, vinegar, curry, and strong alcoholic drinks** and the like are chemical irritants and should clearly be avoided. For the same reason chloral hydrate is an unsuitable hypnotic for the sufferer from peptic ulcer.

**Aspirin.**—The possibility that aspirin might act as an irritant to the gastric mucosa, and thus cause melaena, was raised to me some years ago (Douthwaite, 1938). Later, Lintott and (Douthwaite and Lintott, 1938) carried out gastroscopic observations to determine whether this was in fact the case. They were able to show that an inflammatory reaction developed around particles of aspirin lying on the lesser curvature in 80 of subjects. The greater-curvature mucosa failed to show this change, no doubt because it is more protected by mucus. The failure of Wolf and Wolff to produce an aspirin reaction in the mucosa of Tom may be attributed to this fact or to their subjects belonging to the 20% resistant group. Since our communication on this matter confirmatory evidence has been plentiful. We were able to show that calcium aspirin in solution was entirely free from harmful effects. When the drug is indicated it is this form which should be prescribed.

### After-treatment

Drugs have but little place in therapy once the ulcer has healed. That is to say, after two months of thorough treatment it is seldom necessary to add drugs to the advice we give for the regulation of the patient's habits. Adequate time for meals, thorough mastication, extra food between meals, avoidance of chemical irritants, nine hours in bed nightly, and the refusal to attend to the telephone during

meals or at night are far more important than dietary schemes, which are unnecessary, and drugs.

We know that the high gastric acidity persists and that the exaggerated peristalsis often subsides if the patient is free from worry and stress. The first sign that it is returning is usually that of vague discomfort before food or of waking in the night for no apparent reason. I believe that this gastric unrest precedes duodenal ulceration. If I am right its prompt control should prevent the relapses which hitherto have been a reproach to our therapeutics. Therefore, when such early symptoms are noticed, or again during periods of mental fatigue, worry, and stress, the administration of belladonna alkaloids should be resumed and be continued until the patient has been symptomless for a week. It is especially the night dose which is of value. Alkaline or antacid preparations have no place in therapeutics at this stage: they mask symptoms and encourage relapse.

### Summary and Conclusions

The value of belladonna and its correct administration in treatment of duodenal ulcer are described. The relationship of ulcer pain to acidity and hypermotility is discussed. The use of antacids is considered. The value of phenobarbitone and cannabis indica is described. Reference is made to certain substances in common use which aggravate peptic ulceration.

Belladonna reduces gastric and duodenal spasm and the emptying rate of the stomach. It does not affect acidity. To be effective the dose must be large enough to cause persistent dryness of the mouth. The operation of vagotomy is unjustifiable. Alkalis and other antacids have such a transient and variable effect on gastric acidity that they might well be discarded as of little value. If given they should be combined with the administration of olive oil. Their danger lies in the masking of symptoms while the disease progresses. Continuous milk-drip-feeding often completely neutralizes free hydrochloric acid in the stomach. Cannabis indica is a valuable sedative for use in the acute phase.

The cannabis indica used in these experiments was kindly supplied by British Drug Houses, Ltd.

Dr. Simon Flexner, who was born in 1863 and died in 1946, is commemorated in a pamphlet issued by the Rockefeller Institute for Medical Research, printing speeches delivered on June 12, 1946, at a memorial meeting. In 1902 the Board of Directors requested Dr. Flexner to state his views on the establishment of a research institute, and in 1903 he went to New York to take charge of the Rockefeller Institute's pathological laboratories, becoming Director of the Institute in the same year. One of the speakers quotes from a speech he made in 1933: "There are no closed compartments in nature into which man, animals, and plants can be separately placed. All are related organically and, as we may say, united physiologically and pathologically. . . . If, therefore, we would learn, and through learning grow more powerful and effective to prevent and cure disease, to lengthen life and to increase happiness through security in all its various forms, then we should endeavour to advance in biological knowledge, which alone can free us still further from the evils of disease."

## BORNHOLM DISEASE IN THE TROPICS

BY

W. M. JAMESON, M.D., D.P.H.

Formerly Wing Commander, Medical Specialist, R.A.F.V.R.

AND

D. M. PRINSLEY, M.B., B.S.

Formerly Squadron Leader, Medical Officer, R.A.F.V.R.

An outbreak of Bornholm disease occurred at Aden in the late hot season of 1946. Between Aug. 17 and Oct. 25 we saw 35 cases. This malady has at various times been reported from Northern Europe, U.S.A., Britain, Southern Australia, and more recently from Egypt. So far as we are aware only one previous outbreak of the disease has been reported in the Tropics (McDaniel, 1944), although conversation with Service colleagues has indicated that it is not unknown in parts of tropical India and in Singapore. Aden, although a busy port of call on the East-West routes by sea and air, is nevertheless a relatively small and well-defined community, or rather collection of communities, and eminently suitable for studying an epidemic. All our cases were treated in the R.A.F. hospital, with the exception of two admitted to neighbouring sick quarters, two seen at their home (family of an R.A.F. officer), and one Arab taxi-driver who attended as an out-patient.

The same basic syndrome, with minor variations, has been described under many titles—"epidemic muscular rheumatism," "devil's grip," "epidemic myalgia," "Bornholm disease," "epidemic myositis," "epidemic pleurodynia," and "acute benign dry pleurisy." The condition is infective in origin and almost certainly primarily a lesion of the diaphragm, the exact nature of which is not clear. In view of this we have preferred to retain, for the present at least, the somewhat meaningless title first given to the syndrome by Sylvest (1934)—namely, "Bornholm disease."

With the exception of one case (the Arab taxi-driver) the outbreak was confined to personnel of the Services and their families. The age incidence, therefore, was such as might be expected from any condition affecting the Forces (Table 1). The incidence among officers and other ranks was: officers,

TABLE 1.—Age and Sex Incidence

Age:	0-10	10-15	15-20	20-25	25-30	30-35	35-40	40-45	45+	Total
Males . .	0	1	6	16	3	2	0	2	0	30
Females	0	1	0	1	1	1	1	0	0	5
Total	0	2	6	17	4	3	1	2	0	35

6; officers' families, 3; other ranks, 24; other ranks' families, 2. The ratio of British officers to other ranks in Aden is approximately 1:13. The relatively high incidence of the disease found in officers is thus in accordance with the Egyptian experience of Scadding (1946), who noted a "more common incidence among officers than among other ranks."

### Clinical Features

**Mode of Onset.**—The onset was usually abrupt, with pain, headache, and some degree of fever as the most constant features. Only five cases suffered from upper respiratory tract catarrh, for periods varying between a few days and three weeks, before the onset of classical symptoms. Two cases had prodromal colic and diarrhoea, while a further two complained of lumbar backache for a few days previous to the attack. It is difficult to assess the significance of these various prodromata, since the commonest ailments seen in Aden are probably upper respiratory tract

infection, non-specific diarrhoea, and short-term fevers giving rise to various combinations of aches and pains.

**The Pain.**—The onset of pain was usually sudden and came on either at rest or after exercise. Thus one patient attributed his pain to the fact that he had spent an afternoon on the beach throwing stones. Another was seized with pain after riding, while several had been taking more violent exercise—for example, soccer and hockey. It seems most likely that these were all *post hoc ergo propter hoc*. As a rule the most acute pain was felt at the onset, although in a few cases (see below) an equally if not more severe attack was experienced in a recurrence. Two types of pain were observed. The first and most common was described as "sharp," "cutting," or "knife-like," while the second was of a constrictive nature, one patient saying that the sensation was like having "tight webbing strapped round the lower chest." The pain was always worsened by respiratory effort, as in deep breathing, coughing, and yawning, and even by movement in bed. The position of greatest comfort in bed varied. Quite a number preferred lying on the affected side, while an equal number preferred to lie flat on the back. A few cases achieved comfort from being propped up in bed, and some from lying on the sound side. The pain was felt along the right or left costal margin, in the epigastrium, or in various combinations of these sites. In a few cases tightness across the anterior chest was present. Two cases had no complaint of pain, but only a febrile upset consistent with the disease, and both developed orchitis in convalescence. The actual site of pain at the onset is shown in Table II. It will be seen from this table

TABLE II.—Distribution of Pain at Onset

Site of Pain	No. of Cases
Right costal margin .. .. .	6
Left .. .. .	4
Epigastrium .. .. .	8
Right and left costal margin .. .. .	4
Right costal margin and epigastrium .. .. .	3
Left .. .. .	3
Right and left costal margin and epigastrium .. .. .	Nil
Tightness, anterior chest .. .. .	2
" + epigastrium .. .. .	3
Febrile upset only .. .. .	2
Total .. .. .	35

that there was no particular predilection for any one of the sites usually involved. Spread of pain was observed in 11 cases. Of these, eight showed final involvement of both costal margins and epigastrium, while two showed spread from the epigastrium to one side, and one from one side to the epigastrium. Referred pain was relatively common, being present in 11 cases. In several instances this was actually more severe than the pain around the lower chest. The sites affected were: shoulder-tip (bilateral), 3 cases; shoulder-tip (unilateral), 5; interscapular, 2; umbilicus to groin, 1 case. The shoulder affected was in direct relation to the side of the lower chest affected. The duration of the pain is given in Table III. It will be seen that 24 of the 33

TABLE III.—Duration of Pain in Days

Days:	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	23
Cases:	—	4	8	2	4	1	5	—	2	—	2	1	—	1	1	—	1	1

cases were entirely free from pain in from two to seven days. The longest recovery time was 23 days. It should be noted that these times are for *complete* clearance of the pain. Exacerbations were of frequent occurrence, but there was no real instance of relapse. In several cases the initial pain had almost, but never entirely, disappeared before recurring in an equally and sometimes more severe form.

**Headache.**—Headache was present in 18 of the 35 cases. In 11 it occurred at the onset, while in the remaining seven it came on in from two to seven days. The post-onset headaches were always more severe than the others, and almost amounted to a definite complication. The pain was excruciating, being frontal in three instances and generalized in four. In one case (D. M. P.—see below) the headache was associated with signs of meningeal irritation and was severe enough to warrant lumbar puncture. The cerebrospinal fluid, although showing a very slight increase in pressure, was normal in every other respect. The duration of the headache in its severe phase varied from one to four days, but occasionally the patient was left with a "heaviness" or dull ache for several days longer.

**Pyrexia.**—With one exception every case was pyrexial at the onset. Twenty-two had temperatures not exceeding 100° F. (37.8° C.), seven between 100° and 102° F. (37.8° and 38.9° C.), and five over 102° F. The highest temperature noted was 105° F. (40.6° C.), but the higher temperatures were never sustained beyond a single recording. The chart usually showed a fairly rapid return to normal, 28 cases being normal within four days, 32 within seven days, and 34 within 12 days. The pulse rate for the most part was in accordance with the temperature.

**Sore Throat.**—Fourteen patients complained of soreness of the throat in the initial phase. All of these presented a generalized inflammation of the fauces without exudate. Throat swabs were examined in six of these, with the following cultural results: *Staph. albus*, 1 case; *Staph. aureus*, 1; non-haemolytic streptococcus, 1; haemolytic streptococcus and *Str. viridans*, 1; *Staph. albus*, non-haemolytic streptococcus, and *Str. viridans*, 1; no growth. 1. Throat swabs were also examined in six cases without sore throat, the result being: *Staph. albus* and non-haemolytic streptococcus, 3 cases; non-haemolytic streptococcus, 2; *Staph. albus*, 1 case.

**Other Symptoms.**—Anorexia was fairly common (21 cases). Nausea was present in two cases, vomiting in one. In two cases cough with sputum was troublesome in the acute phase. Pain in the lower limbs was observed in one case. The bowels showed no great change from the normal, diarrhoea being present in six cases, constipation in five.

**Physical Signs.**—Examination of the chest revealed no abnormal signs, except in one case in which a very distinct pleural rub developed on the sixth day of the disease and lasted for eight days. The rub was unusual both in its intensity and in its wide distribution over the chest, and it could be demonstrated by palpation as well as by auscultation. It seems probable that it was due to a super-added fibrinous pleurisy. Repeated clinical and radiological examination showed no signs of any effusion. Subcostal tenderness was present in 16 patients—unilateral in 10, bilateral in three and epigastric in three. Upper abdominal guarding and rigidity were noted in only four cases. Cutaneous hyperaesthesia was not a feature of this outbreak, but was observed in four cases. It was localized to the costal margin and corresponding lower part of the chest.

**Radiological Findings.**—X-ray films of the chest were taken in 25 of the cases, while 21 were screened in the acute phase of the illness. The diaphragm was freely mobile in every case, and no abnormality was found in the lung fields.

**Haematology.**—Twenty-four cases were subjected to blood examination, comprising red cell count and haemoglobin estimation, white cell and differential count, and erythrocyte sedimentation rate. The red cells varied between 4.2 and 5 millions per c.mm. and the haemoglobin between 80% and 100% (Sahli). The colour index was

invariably around 1. There was no abnormality in the red cells, and no abnormal cells were present. These findings are in accordance with those obtained in healthy persons in Aden. The white cell counts were: Under 8,000 per c.mm., 2 cases; 8,000-10,000, 10; 10,000-12,000, 10; 12,000-13,000, 2. Differential counts showed that any increase in cells was in the polymorphonuclears. Lymphocytes, monocytes, and eosinophils showed no departure from normal. The erythrocyte sedimentation rates (Westergren method) in the acute stage of the illness were:

0-15 mm. in 1st hour	No. of Cases
15-20	5
20-30	4
30-40	6
40-50	2
50-60	4
60-70	2
	1

The erythrocyte sedimentation rate, noted at weekly intervals, showed a return to normal in periods varying between seven and 21 days, thus revealing a very distinct lag behind clinical clearance. In the cases developing orchitis in convalescence (see below) a distinct rise in the E.S.R. was noted in six instances, while in a further six the progress of the E.S.R. to the normal figure was uninterrupted. (Note: 0-15 mm. in the first hour was regarded as a normal figure for men in Aden.) Blood culture was carried out in only one case. The culture remained sterile.

**Complications.**—Orchitis was by far the most outstanding complication, occurring in 12 of the 30 male cases. It was always unilateral, and affected the right and left sides equally. There was usually an accompanying mild febrile reaction. The day of disease on which the orchitis developed is shown in Table IV. The orchitis cleared for

TABLE IV.—Development of Orchitis in Relation to Day of Disease

No. of cases	Day of Disease												
	1-7	8	9	10	11	12	13	14	15	16	17	18	19
..	—	1	—	1	—	3	1	—	—	4	1	1	1

the most part in two to six days, only one case lasting as long as 10 days. There was no apparent corresponding ovaritis in any of the female patients. Headache developing after the onset was, as already stated, of such intensity as to be classed as a complication, and was present in seven cases. Actual encephalitis or meningo-encephalitis, which has been reported in other outbreaks, was not observed by us. Pleurisy has also been described as a complication. One case (see above) developed a marked pleural rub, which we considered to be due to a fibrinous pleurisy. Physical signs disappeared in eight days and x-ray findings were normal.

#### A Personal Account of the Disease

One of us (D.M.P.) developed the disease, and it is considered worth while to include his personal account of the illness.

"The first sign of illness was noticed in the morning of Sept. 2, 1946, when upper abdominal pain commenced. The pain was quite localized in the central epigastrium; it was of a constant aching character and slowly progressive in severity, aggravated by movement as a whole. By 2 p.m. there was so much discomfort that I was unable to walk about, had no appetite, and felt ill. Aspirin was taken without effect. By 6 p.m. the pain had moved to the right costal margin and was definitely affected by movements of the diaphragm. There was also a constant aching sensation in the right shoulder-tip. The temperature was 101.8° F. (38.8° C.). A slight irritating cough appeared and there were the usual pyrexial symptoms of headache, giddiness, etc. Later that night there was a short rigor

followed by profuse sweating. Sleep was impossible owing to general discomfort.

"The next morning the temperature was 103.8° F. (39.9° C.) and the pain was severe in the right lower chest and back. There was marked cutaneous hyperaesthesia of the anterior chest and upper abdomen. During the day the temperature fell to 101.8° F. (38.8° C.) and pain subsided, being noticeable only in the lumbar region. On Sept. 4 I felt perfectly well again. My appetite returned, the cough disappeared, and apart from slight backache there was no discomfort. The temperature was normal.

"In the early hours of the 5th the pain in the right side of the chest returned, exactly the same as before. The temperature was 99.4° F. (37.4° C.). By midday the pain in the right side ceased and was replaced by a similar pain in the left lower chest, with aching in the left shoulder-tip, and aggravation of the symptoms occurred with diaphragmatic movements. By 2 p.m. the temperature was 101° F. (38.3° C.), and the pain, particularly in the left shoulder area, was very severe. A hypodermic injection of morphine, 1/4 gr. (16 mg.), gave relief. At about 8 o'clock the same night headache over the vertex began. It was quite the worst headache I have ever experienced, and lasted until the middle of next day. Recovery started on Sept. 7 and was uneventful apart from persistent right-sided headache and vague right chest pain, which lasted for a further week."

Physical examination revealed no abnormal signs other than tenderness, present at first in the epigastrium and along the right costal margin, and later along the left costal margin. X-ray examination and screening of the chest showed no abnormality. *Staph. albus* and a non-haemolytic streptococcus were cultured from the throat. On Sept. 9 the E.S.R. was 21 mm. in one hour and the total white cell count 12,000 per c.mm. (78.1% neutrophils). On Sept. 18 the E.S.R. was 7 mm. in one hour and the total white cell count 10,200 per c.mm. Lumbar puncture on Sept. 6—that is, at the height of the headache—showed the cerebrospinal fluid to be completely normal.

#### Treatment

Treatment was performed symptomatic. The milder analgesics such as codeine and aspirin were largely used and found of some value. Likewise the salicylate group of drugs often gave relief, and these combined with a nightly barbiturate became the routine line of treatment, with the hypodermic injection of morphine, 1/4 gr. (16 mg.), reserved for especially severe cases. The patient was made comfortable in bed in the position he himself chose, and he had what he wished to eat. The appetite usually recovered quite quickly. The headache was often of such severity as to justify the prescribing of morphine. Orchitis was treated simply by rest in bed and the use of a suspensory bandage.

#### Differential Diagnosis

In its epidemic form Bornholm disease is unlikely to be confused with other conditions, but sporadic cases or cases occurring at the start of an epidemic may give rise to considerable difficulty.

(a) *Pleurisy* has obviously to be considered, but the unilateral nature of this condition, together with the absence of chest signs in Bornholm disease, is usually sufficient differentiation. Scadding (1946), however, detected a pleural rub in 11 of his 20 cases, and indeed used the name "acute benign dry pleurisy" for the disease.

(b) *Upper abdominal emergency* has been reported as being simulated by Bornholm disease. Although a few of our cases presented upper abdominal tenderness and muscular guarding there was never any great difficulty in deciding that the case was not an acute abdomen.

(c) *Infective hepatitis* in the pre-icteric stage can give rise to real difficulty. Here we have an illness characterized by pain, tenderness, and sometimes muscular guarding below the right costal margin, by pyrexia, and by general upset. The pain, however, has never the same relation to respiratory effort, and nausea and vomiting are much more constant. The development

of jaundice and the presence of bile in the urine about the fourth to seventh day finally clinch the diagnosis.

(d) *Malaria* was an occasional difficulty, especially those cases showing pyrexial symptoms with pain in the left side and tenderness on palpation below the left costal margin without obvious splenic enlargement. The practice of examining blood films for malaria parasites in all cases of pyrexial illness usually, but not always, provided the answer.

### Epidemiology

The outbreak reported here occurred in the late hot season in Aden, and the weekly incidence of cases, in terms of onset, is shown in Table V. A study of meteorological charts revealed no significant climatic changes from previous years.

TABLE V.—Weekly Incidence of Cases (in terms of onset)

Week ending	No. of Cases	Week ending	No. of Cases
Aug. 23 .. ..	3	Sept. 27 .. ..	3
" 30 .. ..	6	Oct. 4 .. ..	1
Sept. 6 .. ..	9	" 11 .. ..	0
" 13 .. ..	7	" 18 .. ..	1
" 20 .. ..	4	" 25 .. ..	1

The causal agent has never been discovered. The clinical picture, the nature of the complications, and the failure to demonstrate any constant bacterial agent suggest a virus infection, although the mild leucocytosis encountered invariably showed an increase in the polymorphonuclears. The mode of spread, too, is somewhat vague. The various modes postulated have been direct by droplet infection and indirect by infected water, infected food, or insects. In Aden there are several well-defined communities. These include the British Services, Indian Services, European civilians, Indian civilians, and the local native population (chiefly Arabs and Somalis). As previously stated, the outbreak was confined to the British Services, with the exception of the single case in an Arab. The water supply is derived from deep wells and is very pure. It is examined bacteriologically at regular intervals at many points and has always been satisfactory. Moreover, the supply is common to the entire population, and it is difficult to conceive why, if the infection were water-borne, virtually the Services alone should be affected. The native population use goats' milk chiefly. The Europeans use cows' milk, drawing their supplies from two main sources—a civilian dairy-farm and a Services dairy-farm—but there is considerable interchange between the two. No cases of the disease occurred in the staffs of the respective dairies, and bacteriological examination of the milks was satisfactory at the time of the outbreak. Food-borne infection was considered, since food supplies to the British Services, civilians, Indian Services, and natives were all from different sources. An interesting feature in this respect was seen in one camp where a unit of Cingalese troops were living in proximity to an Indian unit. The Cingalese were on British Service rations, while the Indians had their own special dietary. Two of the Cingalese detachment developed the disease, while no cases occurred among the Indians. It must be stated, however, that in spite of the close proximity of these units there was practically no "mixing" between the two. Another most interesting fact was that while the medical staff of the Indian hospital in Aden saw no cases of Bornholm disease, they *did* have an outbreak of mumps among Indian personnel at that time. The R.A.F. and civilian authorities did not have a single case of mumps. The importance of this will be realized when one states that the Indian authorities had several cases admitted with orchitis which they presumed, in view of their epidemic, to be complications of "missed" cases of mumps. Insect-borne disease is unlikely, since Aden is comparatively free from most of the usual pathogen-carrying insects.

While infection conveyed by milk or food cannot be excluded, it seems more likely that the spread is direct by droplet infection. The disease is known to occur in Egypt (Scadding, 1946), and Aden is reached in less than 24 hours from there by the usual air route, thus making the introduction of infection, even with the shortest incubation period, easy. There is surprisingly little "mixing" between Service and civilian personnel in Aden, so that an epidemic in one would not necessarily pass readily to the other. The case of the Arab taxi-driver may be significant, for here was a native, having his own particular diet including goats' milk, who developed the disease in a fairly severe form. Droplet infection would seem the most obvious mode of spread in this instance. There was one example of family infection—an R.A.F. officer, his wife, and two children all developing the disease at varying times within eleven days. At the height of the outbreak five of the hospital staff, including one medical officer, one nursing sister, and three nursing orderlies, all in close contact with cases, developed the disease. Furthermore, one patient, who was in hospital with a left-sided pleural effusion for about three months, contracted Bornholm disease affecting chiefly the right side and complicated by the later development of orchitis. He had been nursed in a general ward which included several cases of the disease, and was almost certainly cross-infected. Lastly, the incidence of faucial inflammation at the onset in 14 cases would seem to lend support to the view that the mode of spread is direct from case to case by droplet infection. The incubation period appears to be a short one. Huss (1934) found it to be about four days, and such evidence as we had agreed with this finding.

### Summary

An outbreak comprising 35 cases of Bornholm disease occurring in Aden in the late hot season is described.

The clinical picture, with minor variations, approximated to the classical syndrome.

Blood examination showed only a slight polymorphonuclear leucocytosis and a raised E.S.R.

Radiological examination showed no deviation from normal.

Orchitis was the most outstanding complication, being present in 12 of the 30 male cases. Dry pleurisy complicated one case, while headache of such severity as to be classed as a complication was present in seven.

The epidemiology is discussed. Direct droplet infection is considered the most likely mode of spread, although food or milk-borne infection cannot be excluded.

Our thanks are due to Group Captain G. P. O'Connell for permission to publish this report; also to Flight Sergeant P. Gaul for his technical assistance with the laboratory work.

The beliefs and rituals of primitive races, by their remoteness from our experience, the obscurity of their significance, and their monotony, are sometimes dull to read about to any but anthropologists; the beat of distant drums, exciting at first, falls on soon-tired ears. Mr. Lewis Lett, in *Savage Tales* (Wadley and Ginn, Dominion House, Bartholomew Close, London, E.C.1: 8s. 6d.), has adopted the form of the short story and used it with considerable imagination to record the myths and customs of some of the Papuan tribes. From many years' experience of living among them he has acquired a remarkable facility at penetrating the native mind and reveals its passions, fears, and aspirations in the setting of the natives' daily life and as part of the characters of individual men and women. His book is the more valuable in that he records in an attractive manner a way of life that is gradually disappearing as the white man's civilization encroaches upon it. The opportunities for intimate contact with the Papuans that he has enjoyed will never recur.

## A NOTE ON THE CAUSATION OF SUDDEN DEATH

BY

ROBERT RICHARDS, M.D., F.R.C.S.Ed.

*Lecturer in Forensic Medicine, University of Aberdeen*

One of the duties of a procurator-fiscal in Scotland is to investigate all cases of death from any form of violence, as well as all sudden deaths and deaths from unknown or suspicious causes. In most cases this is done by private inquiry—though provision is made by statute for fuller inquiry into certain deaths from industrial accidents and other causes—a procedure possessing certain advantages over the coroner's inquest. Part of the procedure initiated by the procurator-fiscal is an examination of the body by the casualty police surgeon, with or without a necropsy, and this note is based on an investigation to elucidate the cause of 1,694 cases of sudden, violent, and suspicious death from 1931 to 1945.

These cases fall into two groups—those in which the actual cause was definitely ascertained post mortem (572) and those in which external examination alone was carried out (1,122). From the former I have deducted 45 cases of newly born children, many of them stillbirths, or non-viable foetuses. On the other hand, many cases of suicide were not subjected to post-mortem examination because the cause of death was obvious—hanging, gunshot wound, cut throat, etc. In suicide, wherever there was doubt as to the cause, a necropsy was done; so all suicides are added to the number of cases where the cause was definitely ascertained. This gives a total of 823 (post-mortem cases (572 less 45), 527; cases of suicide not coming to necropsy, 296), or nearly one-half the total cases, over a period of 14 years. An analysis of these is detailed below.

### Non-violent Group

Of the 823 cases 200 were due to non-violent causes, with the addition of 24 cases of infants under 2 years which have been considered separately because of a tendency to certain special types of death they exhibit. The remaining 599 were due to external agencies, suicide accounting for 365 cases and other external causes (accidental or intentional) for 234. The non-violent group consisted of:

	Cases	Infants
Deaths due to cardiovascular degeneration ..	104 (52%)	
Deaths due to diseases of the respiratory system ..	26 (13%)	17
Deaths due to diseases of the nervous system ..	33 (16.5%)	2
Deaths due to diseases of the gastro-intestinal system ..	15 (7.5%)	
Deaths associated with pregnancy ..	9 (4.5%)	
Other causes ..	13 (6.5%)	5
	200	24

*Diseases of the Cardiovascular System.*—The cardiovascular cases—104 (52% of the total)—form much the largest group, though not so large as in some previously reported lists of causes of sudden deaths. They were grouped as follows:

Coronary atheroma and thrombosis ..	51	} 59.5% of total
Rupture of heart ..	3	
Myocarditis—fibrous or fatty ..	25	
V.D.H. ..	4	
Intracerebral haemorrhage ..	13	
Ruptured aortic aneurysms ..	6	
Pulmonary embolism ..	2	

The first three groups may be considered together. Many cases showed gross atheromatous changes of the coronary arteries, so that these could only with difficulty be cut with a knife; others showed localized atheromatous changes in the arteries, and still others only small isolated plaques—

in all causing such narrowing of the lumen that in some an acute cardiac ischaemia and death, probably from ventricular fibrillation, resulted and in others the narrowed area formed a nidus for thrombus formation and cardiac infarction. If death did not occur at once it might follow in a few days from rupture of the heart through the softened area supplied by the thrombosed vessel, as in the three cases mentioned. Cases showing temporary recovery resulted in myocardial changes, diffuse or localized, with impaired cardiac function. In four cases this fibrosis resulted in a cardiac aneurysm, but in no instance did this rupture. Included in this group are four cases of gross enlargement of the heart which on section showed fatty degeneration of the muscles. One case of coronary embolism was seen in which there were many vegetations on the aortic cusps and a raw area where one of these had become detached; it was found plugged in the right coronary artery, and was about the size of a grain of rice. In four others the main lesion was valvular—two mitral stenosis and two aortic stenosis and incompetence. These also showed evidence of fibrosis of the myocardium. There were 13 cases of cerebral haemorrhage (apart from subarachnoid haemorrhage), and all of them gave evidence of arteriosclerosis with concomitant enlargement of the heart. Eight showed that the haemorrhage arose in the neighbourhood of the internal capsule and five were cases of pontine haemorrhage. Possibly the more rapid termination in cases of pontine haemorrhage resulted in a greater proportion of those being investigated as sudden deaths than in the ordinary cases, which are usually seen by a doctor before death occurs. Of the six cases of ruptured aneurysm three were saccular aneurysms of the aorta; the other three were dissecting aneurysms arising from atheromatous ulceration. Of two cases of pulmonary embolism which came to necropsy one resulted from a thrombosis of varicose veins extending into the iliac veins; the other followed 10 days after a confinement.

*Diseases of the Respiratory System (26 Cases).*—Of these deaths 19 resulted from pneumonia, mainly of the fulminant influenzal haemorrhagic type, which in two cases caused death within four hours of apparent onset; two were due to bronchiolitis and one to status asthmaticus. Four were the result of haemorrhage from tuberculosis, death being due to asphyxia from intrabronchial clotting rather than to the actual blood loss.

*Diseases of the Nervous System (33 Cases).*—Cases of subarachnoid haemorrhage form more than one-third of this group. In only a few was it possible to demonstrate the actual congenital aneurysmal dilatation of the vessel—though it is interesting to note the finding of an unruptured aneurysm the size of a hazel-nut in a case in which death was due to violence. The youngest subject in this series was 10 years and the oldest 59. The following table shows the usual age distribution of cases of this type.

	Present Cases	Magee's 150 Cases
Under 20 years ..	3	9
20-30 ..	1	76
30-40 ..	2	56
40-50 ..	5	9
Over 50 ..	2	—

Six cases occurred in asylum inmates and were due to exhaustion from acute mania, five were cases of cerebral softening from cerebral thrombosis, and three were brain tumours with acute oedema of the brain. There were three cases of fulminant cerebrospinal meningitis—two in brothers who took ill within two days of each other, each dying after less than one night's illness. The third died after eight hours' illness and showed the typical

Waterhouse-Friderichsen syndrome with gross haemorrhage into both adrenals. Of the others, one was a case of general paralysis of the insane in which death was due to idiosyncrasy to arsenical drugs, one of status epilepticus, and one of hydrocephalus.

**Diseases of the Gastro-intestinal System (15 Cases).**—Acute perforations accounted for nine cases, intestinal obstruction for four cases. One case resulted from haemorrhage from a gastric ulcer, and one from colitis which suggested mercurial poisoning, but all analyses were negative.

**Diseases Associated with Pregnancy (9 Cases).**—Four of these resulted from toxæmias of pregnancy; four were the result of abortions—three from sepsis and one from air embolism; and one was an ectopic gestation.

**Other Causes (13 Cases).**—The only interest of these 13 cases lies in one case of Addison's disease, two where starvation was the cause, and two others where in the presence of lymphatism and absence of any other apparent cause the deaths were attributed to status lymphaticus.

**Infant Cases.**—In addition to the 200 cases above listed there were 24 post-mortem examinations on infants. These have been kept separate because the majority of these are of one type. The usual history is that a young child is put to bed after a feed, either apparently quite well or with only a mild catarrhal cold, and in the morning is found dead in its cot. These infants are frequently proved to have died from pneumonia. A dramatic occurrence was in twins 4 months old. Twin A had a very mild cold the previous day, and there was no history of any further illness. Twin B had no history of illness at all. At 8.30 a.m. the mother tucked both children in their cot, apparently well, and went to her washing-house to soak in her clothes. On her return at 9.30 both twins were dead. At necropsy both were found to have had pneumonia, Twin A in a more advanced stage than Twin B. Of the 24 cases in this group 12 had pneumonia: four were due to asphyxia, probably overlying; two to cerebrospinal meningitis; one to a hepatoma, and one to total infarct of the kidney. The other four were one case each due to cerebral haemorrhage (from labour), colitis, bronchitis, and status lymphaticus.

#### Deaths due to External Agencies

This group of deaths, numbering 599, occurred from the following causes:

Suicides (necropsy) .. .. .	69
Suicides—examined externally only .. .. .	296
Injuries, wounds, and burns .. .. .	150
Associated with anaesthetics .. .. .	32
Asphyxias, drowning, strangulation, etc. .. .. .	20
Poisonings .. .. .	21
Other causes .. .. .	11

**Suicides (365 Cases).**—It will be seen that suicides form a large proportion of the total. The interest of this group lies in the method chosen and in the evidence of imitation in the recurrence of similar methods of self-destruction about the same time, especially noticeable in the coal-gas and precipitation groups. "How oft the sight of means to do ill deeds makes ill deeds done." The following is an analysis of the methods adopted:

Coal-gas .. 144 (40%)	Hanging .. 14 (3.8%)
Drowning .. 123 (33.6%)	Cut throat .. 14 (3.8%)
Poisoning .. 37 (10%)	Gunshot wounds .. 12 (3.2%)
Precipitation .. 18 (4.9%)	Trains .. 3 (0.8%)

As is usually seen, coal-gas provides the majority of cases, though cases of drowning approach the same figure, perhaps from the proximity of harbour, sea, and rivers in the area. Of the 37 cases of poisoning, lysol caused 18, again illustrating the usual habit, 11 were due to narcotics (barbiturates, chloral, bromides, and chloroform), three to prussic acid (occurring in two chemists and a laboratory

attendant), two to corrosive sublimate, and one each to arsenic, strychnine, and aspirin. The other types of suicide call for no comment.

**Deaths due to Injuries and Wounds (150 Cases).**—These generally are of little pathological interest. Head injury was responsible for 90, rupture of organs for 28, multiple limb injuries for 12, and fracture of the spine for 6; nearly all the cases in these groups were caused by motor-car accidents.

**Deaths Associated with Anaesthetics (32 Cases).**—Of these cases 17 could be attributed directly to the disease which created the necessity for operation or to post-operative shock—for example, gangrene of leg, two cases (one with aortic thrombosis); cancer of breast and stomach, uterus, and prostate; toxæmia from pelvic abscess and gangrenous appendicitis; and post-operative haemorrhage, from a venous cyst and from gastrectomy. Of the cases where the anaesthetic played a major part in the cause of death three followed the inhalation of blood in throat and nose cases and two from the inhalation of vomit. One was a case of circumcision with status lymphaticus and one with hydrocephalus which collapsed on being given 1 1/2 oz. (14 ml.) of ether for the purpose of taking an encephalogram. In six cases—two of tonsillitis, one of mastoiditis, one of tuberculous nodes of the neck, one of antral suppuration, and one for the change of a plaster casing—the anaesthetic alone appeared to be responsible for the collapse. Two cases followed the application of a 2% amethocaine hydrochloride (decicain) spray—one a tumour of the lung and the other a case of bronchiectasis. The anaesthetic was given to permit of a bronchoscopy, and in both cases generalized convulsions set in within a few minutes and death occurred very shortly afterwards.

**Deaths from Poisoning (21 Cases).**—Six of these were accidental deaths from carbon monoxide from stoves or coal-gas: seven were the result of asphyxia in alcoholic coma; four were caused by drinking the synthetic methanol; and one each from phosphorus (rat paste used as an abortifacient), hydrocyanic gas (in a ship fumigator), quinine (also used as an abortifacient), and lysol applied externally as a dressing in mistake for eusol.

**Asphyxias, Drowning, etc. (20 Cases).**—These include 15 cases of accidental drowning, one accidental strangulation, and four cases of choking on foreign bodies—two in lunatics (a bun and an oatmeal pudding being the offending agents) and two in children from a bean and a particle of food.

**Other Causes (11 Cases).**—Of the 11 cases so classified two resulted from tetanus, two from pyæmia, and two from septic abortion. One case of oedema of the glottis occurred in a schoolboy who was kicked on the neck in a game of football and died within 20 minutes.

An interesting feature of this group is that in 16 of these cases of death from all classes of violence a charge of murder or culpable homicide followed. Three were in children murdered by an insane mother by coal-gas; three were head injuries; three resulted from strangulation—two manual and one with a handkerchief; two from cut throats; and one each from fracture of the spine, stabbing, shot-gun wound, and lysol—this last in a child murdered by its mother, who also committed suicide with lysol.

#### Cases Not Examined Post Mortem

Of the 1,122 cases in which external examination alone was carried out, 296 suicides have already been dealt with: 12 others related to newly born children and are discounted for reasons previously stated. This leaves 814 cases, of which 404 were cases of sudden death, 305 cases of injury, etc., and 105 infant cases. In a great number the cause of

death was not conclusive, so it is undesirable to base any conclusions on the figures; but experience of large numbers of these cases allows an examiner to group the probable causes of death with reasonable accuracy for registration purposes.

Cases of sudden death .. .. .	404 cases
Cardiovascular group .. .. .	357
Respiratory diseases .. .. .	21
Nervous system diseases .. .. .	8
Gastro-intestinal diseases .. .. .	3
Miscellaneous causes .. .. .	15

Here the outstanding feature is the proportion of deaths (85%) attributed to cardiovascular causes. This is not surprising when one considers that most of these were of people collapsing in the street or at work, or found dead in bed. In ordinary times many of these cases would have come to necropsy, but as nearly half occurred during the war years, when post-mortem examinations were reduced to a minimum, they were ascribed to the most likely cause as adjudged from the previous history and mode of death. In all, 318 deaths were thus considered to be due to coronary thrombosis and myocarditis: 11 to valvular diseases; 22 to cerebral haemorrhage; one to ruptured aneurysm, and five to pulmonary embolism.

*Deaths from External Agencies (305 Cases).*—These deaths were due to the following causes:

Injuries:	101
Fractured skulls .. .. .	25
Ruptured organs .. .. .	25
Fractured limbs and spine .. .. .	14
Burns .. .. .	2
Exposure .. .. .	4
Other causes .. .. .	70
Drowning .. .. .	22
Accidental carbon monoxide asphyxias .. .. .	36
Associated with anaesthetics .. .. .	6
Poisons .. .. .	

The first point of interest here is the comparison of the accidental deaths from inhalation of carbon monoxide—22 cases plus six that came to necropsy, 28 (16%) in all—with the 144 (84%) such cases due to suicide. The six poison cases were all due to alcohol. Nearly all of the 36 deaths associated with anaesthetics were due to the condition necessitating anaesthesia or to post-operative shock or haemorrhage—hence necropsy (especially in the war years) was not done. For example, 13 were cases of malignant disease and 7 were abdominal emergencies. Three special cases may be noted: one of tetanus which ended in death during a spasm while receiving chloroform; another that of a child of 23 months with a tuberculous lesion of the skull who received 40 ml. of a 0.5% solution of "novocain," followed by a nitrous oxide, oxygen, and ether anaesthesia, in which the local anaesthetic was certainly in excess of a safe dosage; and a third case, that of a man suffering from a deflected septum who had this treated locally with a swab of adrenaline dipped in cocaine crystals and died in convulsions within a few minutes, presumably from poisoning by cocaine owing to idiosyncrasy to the drug.

*Infant Cases.*—The 105 infant cases show the same tendency as the post-mortem cases: 55 were regarded as due to respiratory causes—50 to pneumonia and 5 to bronchitis—21 were asphyxial deaths, mostly accidental over-laying; 13 were due to convulsions, nine to prematurity, and five to acute infections—measles (three) and whooping-cough (two).

### Conclusion

Exact inferences may not be drawn from the figures given, but there seem to be three points which deserve some emphasis: (1) the outstanding predominance of cases of cardiovascular degeneration as a cause of sudden death—461 (76%) out of 604 cases; (2) the frequency of pneumonia as a suicidal agent; and (3) the frequency of pneumonia (50%) as a cause of sudden death in young infants.

## HEMIPLEGIA IN YOUNG ADULTS

BY

G. JOLY DIXON, M.A., M.D., M.R.C.P.

Strokes in the elderly are usually regarded as a manifestation of cerebral vascular disease, while in the young adult they are usually thought to be due to some extraneous cause. The purpose of this paper is to emphasize both the obscurity of aetiology and the frequency of strokes in young adults.

The cases selected for study are all instances of unilateral pyramidal palsy seen in Service personnel between the ages of 20 and 40 at the E.M.S. Neurological Centre, Winwick, between 1940 and 1946, and also four civilians of the same age group admitted to the Warrington General Hospital between 1944 and 1946; in all 35. Nineteen of these patients had only minor degrees of hemiparesis, and in these a convincing cause was found. Thus, seven occurred among 30 consecutive cases of cerebral tumour, six among 30 consecutive cases of disseminated sclerosis, three cases of congenital hemiparesis had been accepted by the recruitment board, and two cases of hysteria and a hemiparesis due to syringomyelia completed the total. It so happened that the onset of the palsy in all these 19 patients was insidious.

The remaining 16 patients with more severe palsies all had a sudden stroke; of these, two men suffered cerebral emboli during the course of rheumatic mitral stenosis with pulmonary infarcts (Case 20) and bacterial endocarditis (Case 21). Another in retrospect presumably had suffered a Herxheimer reaction during the treatment of secondary syphilis (Case 22); a fourth must have had a cerebral aneurysm, as his stroke occurred 10 days after a sub-arachnoid haemorrhage; and a woman (Case 24) aged 29 developed a hemiplegia whenever an overdose of insulin was administered in treatment of her diabetes mellitus. A case similar to this last was described by Fischer and Florman (1943), though their patient eventually suffered from a cerebral embolus. It is of interest that Case 21 eventually recovered from the endocarditis after treatment with penicillin, though he was left with an almost useless left hand and spastic leg and auricular fibrillation; while Case 22 recovered sufficiently to be conscripted three years after his stroke.

Eleven of the severely palsied cases were not so readily diagnosed. Of these, two convalescent Service men (Cases 25 and 26) who had no pyramidal signs were at first labelled hysteria; however, they both claimed unilateral loss of sense of position and a field defect on the same side. An almost identical Service case was described by Stewart, Randall, and Riesenman (1943) and diagnosed by them as hysteria. However, in reconsidering these three patients it appeared remarkable that all of them should have mimicked so closely the symptomatology of a vascular lesion in the posterior portion of the internal capsule, and when Case 25 was re-examined two years later the signs were unaltered, except that he had developed choreiform athetotic movements of the affected shoulder and a pneumo-encephalogram demonstrated localized cortical atrophy. Six months after his stroke Case 26 wrote that his condition was stationary. It seems possible that had the frequency of strokes in young adults been appreciated at the time both Cases 25 and 26 would have been differently labelled.

Three of the cases under review had sepsis in the jugular vascular bed on the same side as the brain was affected—namely, in Case 27 a tuberculous gland on the right side of the neck, in Case 28 a Vincent's ulcer on the left tonsil, and in Case 29 a right-sided chronic otitis media. Dowman

(1926) and Purdon Martin (1944) have described strokes in this age group due to cerebral venous thrombosis, and Symonds (1937, 1940) has stressed the importance of sepsis in the middle ear and nasopharynx as a cause of thrombophlebitis of the Rolandic veins. Another soldier (Case 30) gave a history of an unexplained femoral phlebitis six years previously, and at the time of his stroke he was under investigation for an obscure painful lesion in the left lung.

Elkington (1935) described the cases of three young adults whom he concluded to be suffering from cerebral haemorrhage because of the site of the lesion, the suddenness of the onset, and the finding of slightly xanthochromic fluid on lumbar puncture in two who had no other signs of subarachnoid haemorrhage. He compared them with a woman of 27 who died from a pontocerebellar haemorrhage resulting from telangiectasis in this region and another woman, described by Gordon Holmes (1931), who developed a left homonymous hemianopia from an arteriovenous aneurysm in the calcarine fissure. The cases here examined resembled Elkington's in the sudden onset and the site of the lesion, and resembled other vascular accidents in the fact that their condition has changed very little during the period of one to four years they have been under observation. However, abnormality of cerebrospinal fluid was a rarity. Case 25 had a slight increase in globulin and a gold curve of 1221110000, and Case 31 had seven lymphocytes per c.mm. in the cerebrospinal fluid.

It seems probable that Case 31 had a cerebral haemorrhage, as at the time of his stroke he suffered a transient glycosuria and albuminuria. This patient, a soldier aged 30, is of interest as two months previously he had suffered from infective hepatitis. Lescher (1944) and Stokes, Owen, and Holmes (1945) describe four cases of cerebral haemorrhage complicating this disease. In Lescher's case the same time interval occurred as in Case 31. The neurological signs in Case 31 were consistent with a lesion in the right internal capsule, but this lesion was presumably more extensive, as he developed epileptiform convulsions and a pneumo-encephalogram seven months after the stroke showed extensive atrophy of the right cerebral cortex. Stokes *et al.* in describing the necropsy of their Case A state: "The brain contained an area of softening lateral to the right lateral ventricle and a large haemorrhage into the right caudate nucleus." Had this patient survived he would presumably have presented an almost identical clinical picture to Case 31, except for the site of the palsy.

No other patient showed evidence that the vascular atrophy was due to haemorrhage. One patient at least, a housewife aged 26, presumably had a cerebral embolus, for on admission she was found to have a cloudy wedge-shaped area lying on either side of a pair of vessels in the upper temporal sector of the left retina. These vessels were somewhat obscured near the disk; peripherally, the artery was seen to be empty and the vein normal. It is suggested that this woman's sudden loss of consciousness the day before admission had resulted from an embolus which had broken up in the left internal carotid artery. The smaller part lodged in the retina and the larger part occluded branches of the left middle cerebral artery. The patient had prolonged unconsciousness, which after about ten days gave place to complete aphasia, right-sided spastic paralysis of face, arm, and leg, and loss of sense of position in these limbs. Later, absence of the nasal field was demonstrated in the right eye, presumably due to the local lesion in the retina.

None of these nine obscure cases had any abnormality of the urine, and the cardiovascular systems appeared healthy except that in three Service men when stress was shown during examination a high blood pressure was found

(150/100 in Case 25, 150/100 in Case 26, and 140/100 in Case 31), normal pressures being recorded at other times in these patients. Another associated finding was recent evidence of pulmonary disease; thus, Case 25 was at the time of his stroke convalescent from pneumonia, and Case 30 during the month preceding his stroke had had three attacks of left-sided pleurisy and was found to have x-ray evidence of infiltration of the left mid-lung zone. A patient not previously mentioned was found to have radiological evidence of spreading though symptomless pulmonary tuberculosis, and another stated that two years previously he had had pneumonia. French authors, such as Hartenberg (1930), Trotot (1935), and Vidal (1942), stress the occurrence of hemiplegias during artificial pneumothorax refills, but the transient nature of these catastrophes argues a different aetiology from that in the group under review.

### Summary and Conclusion

It would seem that strokes resulting in permanent hemiplegias are not such a very uncommon accident in young adult life. Although many of these patients show evidence of cardiac disease likely to give rise to emboli, the majority have no such condition. It would appear that this phenomenon may be due to either a venous thrombosis in the Rolandic system of veins or a haemorrhage, thrombosis, or embolus in the cerebro-arterial system. Sepsis in the jugular vascular bed, recent pulmonary disease, and a tendency to abnormal elevation of the blood pressure are frequent associated findings.

I wish to thank Dr. Fergus R. Ferguson for help and advice in the treatment of these cases, Dr. T. S. B. Dick for the notes of the one case I did not see, and Mr. A. S. Kerr for performing the pneumo-encephalograms; also Dr. A. V. Harvey, Regional Officer of the Ministry of Health, for permission to publish.

The first number of *Nutrition, Dietetics, Catering* is an attractive illustrated journal, to appear quarterly, issued by the British Dietetic Association and the Food Education Society (annual subscription 10s.: Newman Books, Ltd., 356-366, Oxford Street, London, W.1). It is intended to provide the latest news on dietetics for catering managers, canteen supervisors, and others responsible for the preparation of food, as well as medical men, and Sir Jack Drummond hopes, in a foreword, that it will contribute to banishing sodden cabbage and the other evils of bad cooking from our tables. As he points out, the standard of cooking in many of our hotels, hospitals, and institutions is deplorably low and we should be more ashamed of it than we are. Prof. Marraek draws attention to the fact that foods may have a nutritive value not apparent from the content of their various nutrients, and comments that the moral of recent investigations is that "animals, human or other, need food—not vitamins or other separate nutrients." An interesting observation made by Prof. Yudkin is that adolescence in the West African is delayed longer than is commonly believed. The psychological changes associated with puberty in girls occur at the age of about 16 or 17, and he thinks it likely that unsatisfactory nutrition is a possible cause. Mrs. Palmström, comparing Norwegian food with English, remarks that though it is similar it is often prepared differently and is eaten at different times of the day. There is no sign of war weariness in Norway. The people are strong and healthy—the women in fact probably working harder than they do in England. She points out that there are many factors contributing to this state of affairs, and wonders if the diet plays any part, in particular the relatively high consumption of meat and fish in conjunction with bread. The journal also includes news items, book reviews, and schemes for training in dietetics.

# STRESS FRACTURE OF A METATARSAL IN A YOUNG CHILD

BY

LEWIS D. RUTTER, M.B., Ch.B.

Late Orthopaedic House-surgeon, Salford Royal Hospital

The following case is reported because of the early age of incidence.

## Case Report

On July 23, 1946, a woman brought her child aged 4 years 9 months to hospital, stating that until the previous day the child had been well; she then complained of pain in her right foot on walking, and it was noticed that she limped. No history of trauma was elicited. There was nothing of note in the child's previous history; walking had never troubled her before.

On examination the right foot was mildly swollen but not bruised, and there was tenderness along the shaft of the second metatarsal. The appearance of the left foot was normal. She had a mild genu valgum. There was no clinical evidence of systemic disease. A skiagram (Fig. 1) showed: (1) A cuff

FIG. 1.—Skiagrams taken on day of admission, showing appearance of the second metatarsal shaft.

of fine new bone formation around the mid-shaft of the second metatarsal except for a small annular area of absence of bone in contact with the cortex. It appeared as if the bone was surrounded by a ring of tissue translucent to x rays.

This appearance has been noted by Sayle Creer (personal communication) in a number of cases of stress fracture of the metatarsal, and he wonders if it masks a very small crack. (2) New subperiosteal bone formation in contact with the whole length of the metatarsal shaft except for the annular area described in (1).

In view of the patient's age a tentative diagnosis of periostitis, possibly tuberculous in origin, was made and a short leg unpadded plaster cast was applied.

On Aug. 30 the plaster was removed and the appearance of the child's foot was normal, the swelling and tenderness having disappeared. A skiagram revealed a clear fracture line across the metatarsal shaft with some separation of the fragments. The fracture showed good union. On Sept. 2, after a fortnight out of plaster, the foot appeared normal and a skiagram showed consolidation of the fracture with nothing to distinguish it from an ordinary "traumatic" fracture.

FIG. 2.—Diagram of the second metatarsal shaft as seen in Fig. 1.

## Discussion

The condition was regarded as one of stress fracture of the metatarsal on the following grounds: (1) The sudden onset of pain on walking without previous trauma. (2) Swelling of the foot (but no bruising) and tenderness of the affected metatarsal shaft. (3) X-ray appearances: the solution of continuity of the shaft and the consolidation of the fracture seen on Aug. 30, and the initial annular area of absence of bone in contact with the metatarsal shaft surrounded by a cuff of new bone. No cortical "nick" or hair-line fissure was seen: both were suggested as criteria for diagnosis by Hartley (1943), but as the skiagram on Aug. 30 showed a fracture line it is probable that the hair-line fissure was visible at some earlier stage. There is little doubt that had there been no displacement of the fragments the final skiagram would have shown complete restoration to normal architecture—said to be characteristic of "march fracture." (4) It occurred as a single lesion in the commonest bone affected by stress fracture; the other bones showed no lesion, nor was there evidence of general bone disease. (5) There was no evidence of systemic disease. No previous report of a case of stress fracture of a metatarsal occurring at such an early age was discovered in the literature. Several cases of stress fracture of the tibial shaft have been recorded in young children (Hartley, 1942); and Roberts and Vogt (1939) reported a case in a child aged 4. Stress metatarsal fractures have their maximal incidence in adolescents and young men, particularly soldiers—the incidence being so great in soldiers that the condition has been described as an occupational disease associated with military training.

My thanks are due to Mr. R. Ollerenshaw and Mr. W. Sayle Creer for their assistance and advice in the publication of this case.

## Medical Memoranda

### Prevention of Peritoneal Adhesions by Transplantation of Amnion

Various procedures have been suggested to prevent adhesions following repeated laparotomy. The main object is to secure normal peristalsis. Glinn, Hoehne, and other authors recommended the intraperitoneal administration of soft paraffin and similar substances; for a time camphor was employed. It was established, however, that the mixture of fats and chemical compounds was noxious. Some workers, believing adhesions to be due to the absence of fibrinolytic ferments, suggested administering Pregel's pepsin solution or "leucoferment." Mayert and Feldmann tried to prevent adhesions by air insufflation. All these procedures have been criticized.

A case is reported here in which defective peritoneum has been replaced by sterile amnion to prevent new adhesions. For this operation only those cases should be considered in which deficiencies of the peritoneum, with severe adhesions, cannot be repaired by the older procedures because they are so extensive and deep that the body itself is incapable of repair. The transplantation of amnion is intended to provide a moist gliding surface ensuring natural bowel movements. Four suitable patients have been found in the course of four years whose condition necessitated the operation.

Though the problem of adhesion formation has been clarified, there is no reliable method of prevention or treatment. It has, however, been shown that besides asepsis, control of bleeding, and delicate manipulation of the tissues, the replacement of peritoneal defects is the most important factor in prevention. We believe that sterile amnion fulfils these requirements. Transplantation of sterile amnion in the course of gynaecological operations was performed in this country

as early as 1937 by K. Burger. Only intact amnion obtained in the first stage of labour should be used for this purpose. Histological examination has shown that there is a close relation between human peritoneum and amnion. To investigate the question of how long sterile amnion can be preserved, pieces of sterile amnion were put in Ringer's solution at 2° C. and then removed severally at six-hour periods and histologically examined. No change occurred in the peritoneum or in the amnion at the end of the first six hours. Nevertheless we performed our laparotomies simultaneously with the caesarean sections in the same operating theatre; thus the amnion remained in the physiological solution only for a few minutes.

We treated four cases with amnion transplantation. The first patient attempted suicide by shooting himself in the belly. In two cases evisceration due to a war injury has caused adhesions. The fourth patient had a stomach perforation followed by hernia of the abdominal wall.

#### CASE REPORT

He was 32 years old in 1940 when his ulcer perforated. The perforation was sutured 18 hours later. The wound separated, and secondary healing lasting many weeks occurred. One year later reconstruction of the abdominal wall was tried, but unfortunately the bowel was injured during this operation. A faecal fistula formed through which faeces were continuously passed. He suffered severe pain, and a chronic ileus developed. Two further operations were performed to relieve the ileus and to close the fistula.

He came to our ward in 1943 with a marked intestinal obstruction which could be relieved by conservative measures. He had constipation lasting for 4 to 5 days at a time and responding only to the simultaneous administration of hypertonic sodium chloride, "doryl," and "prostigmin." A pregnant woman belonging to the same blood group and having a contracted pelvis, with no other indication for caesarean section, was available. Operation was performed on the man simultaneously with the caesarean section. We removed the scar and liberated the intestinal adhesions. In the vicinity of the fistula there were a peritoneal defect measuring about 40 cm. in length and two other defects measuring 15 cm. each. These areas were covered with pieces of amnion, which were held in place by catgut stitches. Primary healing ensued, and the patient left the ward on the twelfth post-operative day. He has been followed up. He is a journeyman mason and has fully recovered.

We have operated similarly on three other patients with small peritoneal defects. They also healed by primary intention. One of them still complains at times. The patients have been followed up for 2 to 3 years. Amnion transplantation should be performed rarely, and only in cases which cannot be repaired by any other method.

### Bilateral Chronic Suppurative Otitis Media with Complications

Mrs. R., aged 34, was admitted to hospital on Nov. 18, 1946, with a diagnosis of bilateral chronic suppurative otitis media complicated on the left side by: (1) Mastoiditis. Sclerotic mastoid (no swelling or oedema over mastoid). (2) Polypi, granulations, and cholesteatomata of the middle ear cavity. (3) Extradural abscess of the middle fossa. (4) Fistula of the external semicircular canal. (5) Lateral sinus thrombosis, extending down the jugular vein.

#### CASE HISTORY

**Past History.**—Known to have had attacks of bilateral otorrhoea since the age of 12. Attacks had lasted 3–6 months, with remissions of up to three months between. Not accompanied by pain or giddiness. Had measles, scarlet fever, and chicken-pox during childhood; not known whether complicated by otitis media. Scarlet fever *aet.* 10. "Rheumatic chill" lasting three weeks *aet.* 19. "Nervous breakdown" *aet.* 19.

**Present History.**—Six weeks before admission she was taken ill with giddiness and generalized headache. After 2–3 days pain in her left ear began and with it otorrhoea and giddiness on pressure over the tragus. All this subsided in a week, but during the next four weeks she did not feel too well and had attacks of giddiness. The ear continued to discharge and her head "felt queer" although there was no severe headache and no earache.

Seven days before admission she was taken ill with sudden severe pain in the ear and considerable headache and giddiness. During

the next seven days she felt hot and had repeated "shivering attacks." No vomiting. During the first week of the illness, however, she had vomited repeatedly.

**On Admission.**—Giddiness on pressure over tragus. Polypi and granulations removed from meatal wall and roof of attic. Lumbar puncture: Normal fluid; pressure normal; culture sterile. There were some signs of meningism but these were not very marked. High fever. Drowsy. Nystagmus, particularly on looking to right.

Put on penicillin 20,000 units three-hourly (total: 1,440,000 units) and sulphathiazole 1 g. four-hourly for three days (total: 18 g.).

**X-ray Report.**—Acellular type of mastoids and therefore difficult to assess degree of infection, but some infection is present in left mastoid. No cholesteatoma.

**Ophthalmologist's Report.**—No signs of any papilloedema. Disks normal.

By Nov. 24 she had failed to respond to treatment despite the fact that the temperature fell dramatically during the first 24 hours. Still showed signs of meningism. Lumbar puncture: Clear fluid; pressure 120 mm.; Queckenstedt test normal on both sides though sluggish—

no great difference between the two sides; fluid sterile on culture and containing only 5 cells per c.mm. Blood count: W.B.C., total 19,200; polymorphs 66%, lymphocytes 25%, monocytes 9%. Smear normal.

**Operation.**—Nov. 25. Left radical mastoidectomy. Hard sclerotic type of mastoid. Caries found in mastoid antrum and middle ear, which was full of cholesteatomata. Extradural abscess of middle fossa and fistula of wall of external semicircular canal. Forward lateral sinus exposed and considered doubtful but not opened. Wound left open.

On Nov. 27 she still had a high swinging temperature. Mastoid reopened. Bone removed posteriorly more than half-way to occiput. Sinus found thrombosed for 1 in. (2.54 cm.) posteriorly to upper knee. Septic clot removed and sinus opened until free bleeding was obtained: Internal jugular and common facial veins ligatured in neck.

Culture of pus obtained at first operation now showed a pure growth of *Proteus*. She was therefore put on sulphathiazole 1-g. four-hourly for six days (total: 42 g.). Three days later the temperature, which was still high and swinging, fell to normal and remained down. Signs of meningism disappeared after the mastoidectomy. The nystagmus disappeared slowly after the second operation and the general condition gradually improved. The ear still discharges. She left hospital on Dec. 24, 1946, with the wound completely healed but a slight serous discharge from the meatal cavity.

#### DISCUSSION

Although the patient was severely ill there was no swelling or oedema over the mastoid process because she had an acellular sclerotic mastoid. In these cases the infection spreads inwards and backwards and so she developed an extradural abscess, fistula of the external semicircular canal and lateral sinus thrombosis.

As meningitis was suspected she was put on full doses of penicillin and sulphathiazole, but these failed to arrest the progress of the disease. The mastoid was of the acellular sclerotic type, and when entrance to the antrum was effected pus gushed out and was obviously under great tension. Culture of pus showed the organism to be *Proteus*, which is penicillin resistant.

A very anterior lateral sinus—hence more ready infection of sinus. When the sinus was opened and septic clot removed the patient made a steady but sure recovery.

#### CONCLUSION

Chronic otorrhoea is a common malady. When intracranial complications develop treatment with penicillin alone or in combination with the sulphonamides does not arrest the disease and surgical intervention is necessary.

A. MACKENZIE ROSS, M.D., D.L.O.

## Reviews

### TWO HEALTH SERVICES

*Health Reform in New Zealand.* By Douglas Robb. (Pp. 104. No price.) London: Whitcombe and Tombs.

*The Doctor and Tomorrow. The Future of Medical Service in Australia.* By Arthur E. Brown, M.B., B.Ch., F.R.A.C.S. (Pp. 136. 3s.) Sydney: F. H. Johnston Publishing Company Pty., Ltd., 34, Jamieson Street.

These two books from the Antipodes are timely and welcome because they are very relevant to the problems which our profession is facing here. Australia is proposing to nationalize medicine; New Zealand did it, more or less, over five years ago. Dr. Robb and Dr. Brown write with authority, for they both occupy prominent positions in the practice and organization of their profession. Both are firm believers in the need for a full medical service freely available to every citizen. Dr. Brown carefully examines the various ways in which Australia might do this; Dr. Robb regretfully comes to the conclusion that the New Zealand way has proved to be a very expensive failure.

The New Zealand Social Security Act of 1938 provided for everybody a free general practitioner service and part payment of hospital treatment. From the outset there was friction between the Government and the B.M.A., and there seems to be small prospect of any early agreement. Dr. Robb ascribes the defects of the scheme largely to the fact that "its impetus was political and its conception almost entirely so." Much of the friction has arisen over the amount and method of medical remuneration. There are no fewer than five ways in which the citizen can obtain medical service. (1) In a few rural areas the doctor is paid by whole-time salary. (2) If the doctor is willing to accept the method he can be paid by a capitation fee of 15s. a year with no limitation of his list. This method, though making some progress, has always been strongly opposed by the B.M.A.; in the first six months after the Act came into operation only some 50 doctors out of nearly 800 had accepted patients under this method. (3) "Fee for service." Here the patient signs a form acknowledging that he has received a service, and the doctor collects monthly from the fund 7s. 6d. for each form. Though not approved by the B.M.A. this method is being freely used. (4) "Refund" plan. The patient pays the doctor his private fee (usually 10s. 6d.), for which he is given a receipt, and with this he gets a refund of 7s. 6d. at the post office. (5) "Token" plan. Here the patient pays the doctor a token fee of 3s. and the latter collects the refund of 7s. 6d. It is not the financial side of the system which makes Dr. Robb so dissatisfied with it, for he believes the general practitioner under any of these arrangements to be better off than he was in the days of bad debts. He dislikes the "fee for service" because it "results in many trifling things being done by the doctor at 7s. 6d. a time that ought to have been done by a nurse or secretary." His fundamental complaint about the service is that it is uncoordinated and far from comprehensive. He grants that some few remote areas formerly under-doctored are now better off, but the tendency still is for doctors to gravitate to the cities. A curious factor in the constantly mounting cost of the service is the great proportion of the income of the fund that is spent on drugs and appliances. It is now 13s. 6d. a head, compared with 16s. 10d. for the general medical service. It would be interesting to know if this "free for all" supply of medicine has lessened the demand at the chemists for proprietary medicines.

Dr. Robb realizes that a country so thinly populated as New Zealand has many difficulties in providing a really full service as compared with Britain. He alludes with envy to some of the features of our new Health Service Act, but he is still hopeful that a really good service may emerge in his country. He is confident that with genuine co-operation between the Government and the profession something infinitely better than the present system could be evolved. He does not absolve the doctors from a share of the blame for the present situation: they should have shown more initiative instead of leaving the politicians to take all the credit (if any). This book is intended mainly for the New Zealand layman, and the author reminds

his readers that "the profession did not conceive or initiate the present system."

Dr. Brown's book deserves the earnest attention of all who are interested in the future of the profession, and especially of those who are concerned with the negotiations on the new National Health Service. The author is convinced that the world-wide movement towards a medical service freely available for all is one which, far from being resisted or thwarted by the profession, should be warmly welcomed. There is much information in the book about the gradual approach of Australia to this problem, but to the reviewer the most striking feature is Dr. Brown's analysis of the various methods of remunerating the profession—not because Dr. Brown is unduly concerned with finance, for he is an idealist and enthusiast, but because he believes that the success or failure of any scheme will greatly depend on the method of remuneration of the doctor. There is no other so cool, logical, and lucid an examination of the methods available known to the reviewer. The fact that the author decisively approves of payment by salary makes it all the more desirable that those who have come to a different conclusion should consider the opposing arguments, especially when they are maintained so competently and so modestly as they are here. There is no ideological nonsense about Dr. Brown. He says that he has been driven inexorably to the conclusion that only by this method can doctors be distributed "in accordance with public needs." He rules out capitation because it profits the doctor to take on more patients than he can manage and does nothing towards solving the distribution problem. As for payment per service, he rejects "any form of practice which leaves medical men and women as private traders in competition with each other."

Dr. Brown is concerned entirely with a future in which free medical service will be available to all. He does not hide his fears of a bureaucracy which fosters uniformity; he does not regard lay control as a serious danger. His main fear is of the politician, and he says, "the prospect of an inferior, badly conceived, politically devised service is a far more dangerous prospect for the public than it could ever be for the medical practitioner." Dr. Brown is to be congratulated on a courageous and lucid examination of a thorny subject. There will doubtless be many attracted, as the reviewer has been, by the logic of his advocacy who will feel that he has not given sufficient weight to the pressure which the politician will be tempted to bring to bear on a profession, no matter how or how well paid, once it has surrendered its status as a free profession.

ALFRED CON.

### GENETICS

*Human Genetics.* By Reginald Ruggles Gates. Volumes I and II. (Pp. 1518; illustrated. £5 for the two volumes.) New York: The Macmillan Company. 1946.

Probably no one except Prof. Gates could have written this book, but, fine though the result is in some ways, we wonder whether anyone, even Prof. Gates, should ever have made the attempt. He covers the whole field chapter by chapter, and there can be few human inherited abnormalities, as well as many other inherited differences, that he does not describe. His knowledge is encyclopaedic and the 5,500 references successfully guide the reader to the key papers and books on each subject. There is an admirable index of 90 pages with full cross-references. It is the text that raises the suggestion whether the author has been too ambitious.

When Prof. Gates is discussing subjects especially familiar to him, and to which he himself has contributed, he presents us with a lucid, balanced, and well-digested summary. The chapter on the blood groups, for example, is excellent. When he was writing the book our knowledge of the rhesus factor had not attained its present clarity, but he explicitly recognized that a successful synthesis was imminent and few outside the ranks of the professional serologists could have achieved so much. One man, however, can have only a second-hand acquaintance with most of this vast subject and its scattered literature, and in many chapters the sureness of touch seen in that on the blood groups is lacking. The running commentary is often a complex and exhausting mixture of the historical, the pathological, the clinical, the genetical, the purely descriptive and the statistical. Some out-of-date opinions seem to have been included from

the previous version of 1929. Sometimes erroneous or fantastic speculations are given the same emphasis as thorough and competent researches and surveys. For example, the account of spina bifida starts with a consideration of experimental work on the frog, followed by a reference to its anatomical features. The author then refers to an instance of three cases in one sibship and a theory of the relationship of the occult to the manifest condition. After that he digresses to its possible relation to the erect posture, with a remark on sex limitation. Next he discusses a study of its relation to nocturnal enuresis, the author of which considered this latter condition to be a simple recessive. Finally he mentions some other deformities with which spina bifida may be associated, and interpolates a paragraph on its frequency in the population. The inquirer who wishes to know whether spina bifida is inherited and, if so, how will not be much wiser, though his attention is directed to useful references from which he may find the answer for himself. In the chapter on the inheritance of normal mental differences, after a few brief references, Prof. Gates starts with an account of Hurst's hypothesis of six factor pairs, but does not point out that a scheme involving six factor pairs would fit almost anything and would be difficult enough to establish even with many thousands of observations on a self-fertilized plant.

One opinion should not be allowed to pass without challenge. On p. 213, in dealing with the usual recessive form of retinitis pigmentosa, Prof. Gates says: "Obviously those transmitting this very serious defect should not have children." If he means that a couple who have had an affected child have a one-in-four chance that any further child will also be affected and would therefore be wise to refrain from having more, many will agree with him, but presumably he means that an affected person or a known carrier should not have children; yet for every such person at least 100 others, quite unsuspected, are carrying and transmitting the gene. The eugenic effect of such abstinence is negligible and there is a far stronger case for the opposite opinion: that a sufferer from a rare recessive defect or a known carrier should not be deterred from parenthood provided he does not marry a blood relative and—as will nearly always be the case—so long as no affected child appears.

In some places this book is clear and authoritative, in others obscure, and in a few misleading. It is unsuitable for the student, but the expert will value it highly.

J. A. FRASER ROBERTS.

## EXAMINING THE EYE

*Clinical Methods of Neuro-Ophthalmologic Examination.* By Alfred Kestenbaum, M.D. (Pp. 384. \$6.75.) New York: Grune and Stratton. 1946.

This well-produced book, an important and welcome addition to the rather limited literature on the subject, contains a large amount of clearly presented and accurately classified information not generally available in textbooks. The author considers clinical entities only incidentally; he concentrates on methods of examination and on the interpretation of findings. An introductory chapter on the optic pathway is followed by one on the field of vision, in which he discusses in detail both methods and field defects. Three successive chapters deal with physical signs in lesions of the optic nerve, chiasma, and retrochiasmal pathways respectively. A further three chapters are devoted to eye muscle palsy, gaze movement, and nystagmus. He gives an account of the different modes of disturbance in symmetrical eye movement in the succeeding chapter, and then discusses abnormalities in the reaction of the pupil; in the concluding three chapters he deals with miscellaneous physical signs, palpebral fissure, and functional disturbances, giving a general survey of the routine neuro-ophthalmological examination.

The text is not easy reading, but this is not the author's fault. His subject has received less attention in the past than it merits; in consequence there is much here that is unfamiliar, though it ought to be widely known. The logical division and subdivision of the text should help the reader considerably, though it is unfortunate that it contains many unusual abbreviations. The book should do much to further the systematic study of ophthalmic neurology.

ARNOLD SORSBY.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Vitamins and Hormones.* Ed. by Robert S. Harris and Kenneth V. Thimann. Vol. IV. (Pp. 406. \$6.80.) New York: Academic Press. 1946.

Papers on recent advances of vitamin and hormone investigations.

*The Intelligent Use of the Microscope.* By C. W. Olliver, A.M.I.E.E., F.R.M.S. (Pp. 182. 12s. 6d.) London: Chapman and Hall. 1947.

Describes how to get the best out of a microscope and includes a chapter on photomicrography; for the student.

*La Silicosis Pulmonar.* By Dr. Hugo Dooner. (Pp. 195. No price.) Santiago, Chile: Zig-Zag, S.A. 1944.

An account of silicosis with a historical introduction, skiagraphs, and bibliography.

*Preventive Medicine and Public Health.* By Wilson G. Smilie, A.B., M.D., D.P.H. (Pp. 607. 30s.) New York: The Macmillan Company. 1947.

The technique of hygiene and public health for the medical practitioner and student.

*Tuberculosis Reference Statistical Yearbook.* By the New York Tuberculosis and Health Association. (No price.) New York. 1946.

A summary with tables of tuberculosis morbidity and mortality in New York with comparative figures from the United States and other countries.

*The Louse.* By Patrick A. Buxton, F.R.S. 2nd ed. (Pp. 164. 10s. 6d.) London: Edward Arnold. 1947.

An account of the lice that infest man, their medical significance and control.

*Medical Services by Government, Local, State, and Federal.* By Bernhard J. Stern, Ph.D. (Pp. 208. 8s. 6d.) New York: The Commonwealth Fund (London: Geoffrey Cumberlege). 1946.

A monograph on the Government Medical Services of the United States.

*Una Epidemia de Peste Bubonica en el Siglo XVI.* By Dr. Don Jose Viñes Ibarrola. (Pp. 133. No price.) Pamplona: Editorial Aramburu. 1947.

An account of a plague epidemic in Spain in the 16th century, with reference to original sources.

*The Glean.* By Warren Chetham Stode. (Pp. 90. 6s.) London: Sampson Low, Marston and Co. 1947.

A National Health Service drama which was reviewed on Dec. 14, 1946 (p. 914).

*The Microscope.* By Theodore Stephanides, M.D. (Pp. 160. 10s. 6d.) London: Faber and Faber. 1947.

An account of the microscope and its use; for students.

*La Désinsertion Extra-pleurale des Symphyses Pulmonaires sous Contrôle de la Pleuroscopie.* By Dr. Jean Brailon. (Pp. 120. 210 francs.) Paris: Librairie Maloine. 1947.

An account of Michetti's operation for pleural adhesions in collapse therapy.

*The Personality of Man.* By G. N. M. Tyrrell. (Pp. 295. 1s.) Harmondsworth, Middx.: Penguin Books. 1946.

Discusses paranormal phenomena, including telepathy, and their significance to man.

*Massage and Remedial Exercises in Medical and Surgical Conditions.* By Noël M. Tidy, M.C.S.P. 7th ed. (Pp. 480. 25s.) Bristol: John Wright. London: Simpkin Marshall. 1947.

This edition includes a short description of carbachol ionization.

*Medical Diseases in Tropical and Sub-Tropical Areas.* By the War Office. 8th ed. (Pp. 396. 7s. 6d.) London: His Majesty's Stationery Office. 1946.

This edition includes new articles on infective hepatitis, leprosy, nutritional diseases, tropical eosinophilia, and D.D.T. Many other sections have been rewritten.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 12 1947

## A CENTURY OF CHEMISTRY

The antiquity of medicine as an art should not obscure the fact that the origin of medicine as a science dates chiefly from the development of chemistry. An important stage in that development will be celebrated in London on July 15-17: the foundation on Feb. 23, 1841, of the Chemical Society, the first organization in the world to make the study of chemical science its specific province. The centenary celebrations were postponed from their original date on account of the war, as also was the Eleventh Congress of Pure and Applied Chemistry, which it had been planned from the beginning should be held in London, as a compliment to the Society. The medical man may see some compensation in the delay, for in the interval his debt to the chemist has become even more evident. Environmental medicine has benefited, in temperate as well as in tropical conditions, from the new insecticides. Blood storage, with its background of chemical experiment and preservatives, has given a new flexibility to emergency surgery; and penicillin, to which the chemist also contributed, has increased confidence in the result. The physician, confronted for the first time in modern medicine with the prospect of widespread malaria and empty quinine bottles, found his position in the end to be stronger and not weaker as a result of the chemist's work.

To concentrate on recent events such as these would nevertheless be to miss the real nature of the chemist's contribution; for these advances, however important in themselves, have been on the surface, whereas the whole structure of physiology has depended on the insight which chemistry alone could provide. Without recognition of the individual nature of different gases, and the power to make their properties the subject of experiment, we could not have understood the function of breathing. Without knowledge of combustion, physiological meaning could not have been attached to the circulation of the blood, nor could even the crudest approach to nutrition have been made. From these necessary beginnings succeeding discoveries have branched out ever more widely; and, as the President of the Royal Society has pointed out,<sup>1</sup> chemistry has benefited in turn from the reciprocal stimulus which biological studies provided. A classic example was the synthesis of urea by Wöhler in 1828, and it may be worth emphasizing that this was only thirteen years before the foundation of the Society. Wöhler's work represented rather the removal of a barrier than the beginning of synthesis in the ordered and modern sense, but, as has since been stated, it provided "a charter of liberty for organic chemists."

Synthetic chemistry proper is generally dated from the work of Berthelot in France, about 1853, on glycerides and fats. The chance discovery of synthetic mauve by Perkins (later President of the Society) in 1856 may seem, however, to have exercised a greater immediate influence on the course of medicine. Apart from its distressing effect on Victorian taste and the obvious stimulus which it gave to the development of a dyestuffs industry it may be said to have paved the way for the introduction of staining techniques in cytology and bacteriology and thus to have provided the technical means for the development of two branches of medical science. Add to this the importance of the methylene blue test in the examination of milk, the many colour indicators now taken for granted, and the development of modern chemotherapy from the partly mistaken doctrine of dyestuff absorption, and some measure of medicine's debt to Perkins's discovery is obtained. To the same period, although obviously unconnected with Perkins's work, belongs the synthesis of the first salicylate. Finally, as one example of an incidental discovery, we may recall that the first use of anaesthetics in surgery falls also within the period covered by the Chemical Society's history.

Contemporary interconnexions between medicine and chemistry are most conveniently illustrated from the Congress programme. Out of the fourteen sections three of particular interest are devoted to biochemistry, food and nutrition, and chemistry in relation to medicine and therapeutics. The biochemists will meet under the presidency of Prof. Tiselius, of Uppsala. He has made many contributions to both protein and carbohydrate chemistry, and both these divisions are well represented, as also is the now rapidly growing chemistry of enzymes. Further subjects include the preparation of purified antibodies, Stacey's work on bacterial polysaccharides, and the nature of the combination of bacterial enzymes with their substrates. All these are investigations of probable importance, and the same may be said also of the first attempt by Francis and Wormald to apply radio-active tracers to the study of immunological reactions. A useful joint symposium on nutrition has been arranged with the section of applied zoology. Recent experience has shown that farm animals, owing to the greater localization of their natural diet, afford opportunities not easily found in human beings for the study of both trace mineral elements and mineral antagonisms. Another recent development has been the recognition that knowledge of calorie requirements, and particularly of physiological adaptation to a low caloric intake, is still incomplete. It is common knowledge among nutritionists that work in the occupied countries of Europe has led to a number of fundamental advances; but, so far as the present Congress is concerned, we must be content with information from France, Belgium, Bengal, and the Far East, and with learning the lessons to be drawn from the Minnesota rehabilitation experiment.

In the medical section chemotherapy occupies, inevitably, the place of honour. Sir Howard Florey will give a general introduction, and Waksman will follow with an account of streptomycin. Shannon's summary of anti-malarial research in the United States may be expected to add something to existing knowledge, particular interest

<sup>1</sup> Robinson, Sir R., *British Medical Journal*, 1946, 1, 943.

attaching to those investigations aimed at producing a less toxic substitute for pamaquin. Papers on the natural formation of thyroxine and on the synthetic oestrogens remind us of the chemist's contributions to endocrinology. On the other hand, chemical carcinogenesis, together with the newer experimental methods used in its study, is perhaps less fully represented than might have been expected. Finally, there is a symposium on industrial toxicology, on which also there have been recent advances in knowledge.

One effect of the centenary celebrations and of the Congress should be to bring home to the medical man a more lively appreciation of the close relation between the two disciplines. In chemistry and physics research has been notably assisted by a comparatively small number of laboratory workers who have so far become biologists as to obtain a real insight into the structure and functions of the living material which they have chiefly investigated. There is no less need, as we have pointed out on another occasion,<sup>2</sup> for medical men themselves to gain some understanding of the chemist's methods and limitations. It is not enough to learn, usually under duress, the names of the principal chemical elements and radicals or the rudiments of systematic analysis, for these accomplishments as such imply no more than that the medical man is an inferior chemist. It is more important for his proper contribution to the partnership that he should understand how chemists think, and, in particular, the ideas and methods which they use in working out structural constitution. In addition it is desirable that he should know something of the powers and limitations of the newer chemical techniques, including, for example, chromatography,<sup>3</sup> micro-analysis,<sup>4</sup> and the research uses of radio-isotopes.<sup>5,7</sup> He need not himself be a chemist, but he should know enough to understand the sort of questions that may usefully be asked.

## FAT ABSORPTION AND METABOLISM

The intervention of seven years of war has broken many of the threads of international co-operation in research, so that accumulated data, new techniques, and fresh conceptions now await integration. As the pattern of post-war developments in research becomes clearer it is apparent that the problem of fat absorption and metabolism has been and is being energetically studied in both the laboratory and the clinical fields in many countries. The striking advances in our knowledge of fat metabolism during the last decade have accentuated the need for an adequate understanding of the mechanism of intestinal absorption of fat.<sup>8</sup> The lipolytic hypothesis of fat absorption,<sup>9</sup> which was generally accepted ten years ago, does not adequately explain many subsequent observations,<sup>10</sup> nor has it formed a satisfactory basis for the investigation of defective fat absorption in human subjects. The problem must be re-

examined in every detail. If the fundamental mechanisms of fat absorption can be elucidated in experimental animals and human subjects, it may be possible not only to correlate the absorption and metabolism of fat but also to gain a clearer conception of the process of absorption in general. A more detailed approach to these problems, tracing each step in the passage of fat from the lumen of the intestine to its ultimate destination in the body, combined with the application of new techniques, should soon clarify our views.

Study of the clinical aspects of fat absorption was intensified during the war because of the high incidence of tropical sprue among British troops overseas<sup>11</sup> and non-tropical sprue among the civilian population in Britain, and these cases were an invaluable means of studying the fat absorption mechanism in human subjects. It is essential, however, that investigations should be carried out on a quantitative basis<sup>12</sup> and that further methods should be devised for the more detailed study of aetiological factors. Best and his colleagues<sup>13</sup> at Toronto opened up a new field of investigation in fat metabolism by demonstrating the lipotropic action of choline. Subsequently other substances affecting the deposition and mobilization of fat from cells have been described. Further experimental studies are required to establish the relationships between these substances and to elucidate their mode of action and their role in normal metabolism. The observations so far made in clinical medicine have given anomalous results. There does not seem to be sufficient information at present on the action and effects of lipotropes in human subjects.

The study of adipose tissue remains largely neglected, although Schoenheimer and his collaborators<sup>14</sup> have introduced a new conception of its dynamic nature. Little is known of the mechanism of fat deposition or its removal from the depots. While cases of obesity have been studied and the application of Newburgh's views<sup>15</sup> has been attended by success in many cases, it is unlikely that clinical problems involving the metabolism and deposition of fat will be solved until the fundamental physiological facts about adipose tissue have been determined. Contributions have been made to many other aspects of fat metabolism. Progress has been achieved in the study of fat oxidation, and a revision of ideas on the relationships of carbohydrate and fat metabolism is leading to a more rational view of ketogenesis. Some years ago Burr and his colleagues<sup>16</sup> demonstrated the importance of certain fatty acids in the diet in animals. The application of these findings to human subjects has been somewhat disappointing, but, again, therapeutic trials have been carried out without any clear conception of the physiological significance of these essential fatty acids in man.

Animal proteins are usually associated with lipoids, and in many instances this association is fundamental to the normal biological activity of the protein material. The nature of these associations and the factors concerned in their stability are largely unknown. Work is in progress in several laboratories, using modern chemical and physical

techniques, to determine the essential data. Since lipoprotein association is concerned in fat transport, membrane structure, blood coagulation, nerve structure, immunological reactions, and probably fatty degenerative changes, the importance of investigations in this field to physiology, pathology, and clinical medicine is likely to be considerable. The absorption and metabolism of fat presents a fascinating research field. It requires the co-operation of chemists, physicists, physiologists, and clinicians. As new facts come to light it is hoped that an adequate physiological basis will be established in human subjects as well as in experimental animals before attempts are made to apply the facts therapeutically, for it is only by building on a sound foundation of proved experimental data that successful clinical application can be achieved.

### INTERNATIONAL MICROBIOLOGY

The fourth International Congress of Microbiology, which before the war was triennial, is to be held in Copenhagen at the end of this month. The Permanent International Commission for the organization of these congresses has been reconstituted and will also meet in Copenhagen to consider the future policy of the International Association of Microbiologists in relation to other scientific bodies. This Permanent Commission consists of representatives of twenty-eight countries. The British representative is Sir Alexander Fleming; the United States is represented by Dr. Stuart Mudd, of the University of Pennsylvania; Denmark by Prof. Th. Madsen; Belgium by Prof. Jules Bordet; Canada by Prof. E. G. D. Murray, of McGill; Eire by Prof. J. W. Bigger, of Trinity College, Dublin; and India by Sir S. S. Sokhey, director of the Haffkine Institute, Bombay. The question for decision will be whether the International Association should ally itself with the International Union of Biological Sciences, forming a section within that body, or should become a separate union in the International Council of Scientific Unions. Through either of these organizations it would be linked with Unesco, and both courses have their advantages. A decision either way would mean only a formal change of status and no surrender of independence. If it is decided to become a section within the International Union of Biological Sciences the advantage would be in the organic connexion of microbiology with other aspects of biology—botany, zoology, genetics, and experimental cytology, and so all these sciences would be under one international umbrella. Apparently the International Union would also publish the reports of the international congresses of its sections with the help of Unesco. On the other hand, there are such strong links between microbiology and the medical sciences that some may think there should be a separate union within the International Council for Scientific Unions. The British and American representatives favour the first of these alternatives.

One of the reasons for the re-establishment of international microbiology is the need for restoring the various collections of type cultures throughout the world and for preparing a world catalogue of the available strains. A new central collection of type cultures has lately been organized at Lausanne under the direction of Prof. Paul Hauduroy, and proposals will come forward at Copenhagen for the association of this centre with the others. Dr. Joseph Needham, head of the Division of Natural Sciences of Unesco, has stated the interest which his organization takes in the furtherance of international scientific unions.

Such unions will serve three primary purposes—as machinery for the exchange of information, as organizers of international congresses, and as channels for the funds which Unesco may provide for international scientific undertakings.

### ETHER IMPURITIES

From the earliest days of anaesthesia the importance of using chemically pure and unadulterated ether has been stressed. The demand for pure ether has not appreciably altered through a century of anaesthesia, and to-day the pharmacopoeias of almost every country lay down stringent chemical and physical criteria for ether which is to be used for anaesthetic purposes. These precautions, however, by obviating impurities which derive from the process of manufacture, do no more than ensure pure ether in the unopened bottles as supplied by the manufacturers. There are other impurities, of which the most important is ether peroxide, that make their appearance as a result of autoxidation during storage. There is still some doubt as to how important these impurities are. From the physical point of view it seems that the presence of ether peroxide renders spontaneous explosion possible. But their effect on the human organism is less certain. In the literature of ether anaesthesia, anaesthetists have repeatedly made them the scapegoat for any complication or mishap which they could not explain without implicating their own human fallibility. Sudden death on the table, post-operative pulmonary complications, vomiting, convulsions, and every sort of difficulty during induction and maintenance of anaesthesia have all been attributed to impurities. In fact, there has been enough feeling on the matter, even without much scientific evidence, to make manufacturers and pharmacists use considerable effort to ensure that ether for anaesthesia is supplied as pure as possible.

In the extensive literature on ether impurities the monograph of Reimers,<sup>1</sup> dealing with the chemical aspect, stands out as a most important contribution. Lindgren<sup>2</sup> now carries Reimers's work a stage further by investigating not only the factors which enhance autoxidation but the biological and clinical effects of using autoxidized ether for anaesthesia. He found that autoxidation is dependent on such factors as the ether storage temperature and the nature and thickness of the glass in which the ether is kept. Lindgren also determined the effectiveness of various inhibitors of autoxidation, particularly diphenylamine. Ether to which such a stabilizer is added shows no appreciable oxidation over long periods of time. Biological tests revealed a close relationship between induction time and peroxide content; the greater the peroxide content the weaker the ether as an anaesthetic and the longer the induction time.

Of even greater interest are the results of clinical tests which Lindgren carried out on over two thousand patients. A clinical comparison with statistical tests was made between samples of pure anaesthetic ether complying with pharmacopoeial standards, autoxidized ether, and ether stabilized by the addition of diphenylamine but kept under conditions which would normally result in much autoxidation. Observations on the ether consumption, induction time, excitement and vomiting during induction, circulatory disturbances, convulsions, and post-operative pulmonary complications were carefully made. In summing up, Lindgren states that there was no significant difference in the actual course of the anaesthesia or in the frequency of post-operative pulmonary complications between the samples of ether used.

<sup>1</sup> *Aeter til Narkose*, 1943, Munksgaards, Copenhagen.

<sup>2</sup> *Acta chir. scand.*, Suppl., 110, 1946.

The work of Reimers and of Lindgren is of importance when, as in the recent war, large stocks of ether are accumulated and the problem of their disposal arises. It is probable that much needless waste of such stocks took place, on the ground that possible autoxidation constituted a hazard to patients. The use of autoxidized ether is nevertheless undesirable, and the question of preventing this process must be seriously considered by ether manufacturers in this country. When a pure ether supply to the patient is ensured the real or imaginary bogey of ether impurities as a cause of bad anaesthesia may at last be laid.

### SPINAL PUMPING

The iron curtain which has become so familiar to the political student of Europe is an effective barrier to the spread of scientific ideas. Behind it, untouched by what we consider the main stream of contemporary medical thought, the Soviet system of medicine has been growing up; the occasional glimpses vouchsafed to us have done little but confirm the belief that it is developing along lines different from ours. Often these glimpses have revealed views which we have been unable to accept and notions which would not fit into the framework of our methodology. Such reasons give an added interest to any paper concerning itself with Soviet medical thought or practice and ensure that a recent publication by Gillman and Gillman,<sup>1</sup> of Johannesburg, will be read with careful attention. These authors report their experiences with Speransky's method of "spinal pumping" in the treatment of rheumatic fever and rheumatoid arthritis.

Speransky, a pupil of Pavlov, believes that the nervous system plays an important part in the genesis of acute and subacute arthritis. The reasons for his belief and the steps that led him to adopt this bizarre method of treatment remain buried in the Russian tongue. To carry out his method a thin lumbar puncture needle is introduced with the patient lying on one side; a 10 ml. syringe is attached to it when cerebrospinal fluid is flowing freely. The process of "spinal pumping" consists of withdrawing 10 ml. of fluid and re-injecting it into the theca; this is repeated about twenty times; it is usually followed by considerable autonomic disturbance, particularly sweating and cutaneous vasodilatation. Seventy cases were treated; 42 of 48 patients with acute or subacute arthritis were distinctly improved—38 indeed recovered completely; 12 of 22 chronic cases were improved. The results are of great interest, and it is to be hoped that others will give this method a trial. Nevertheless the Gillmans' paper is not wholly satisfying. We are told that from "a series of brilliant experiments" Speransky concluded that the nervous system played a major part in the pathogenesis of inflammatory processes, but we are not told what drove him to devise the procedure of "spinal pumping." Our ignorance of these steps does not indicate that the method is without a logical basis, but without this knowledge it is unlikely to appeal to the British physician until its efficacy is established.

### GLUTAMIC ACID

Glutamic acid is an important constituent of brain tissue. It is the only amino-acid known to be metabolized by the brain, in which it increases oxygen consumption. Wheat gluten contains glutamic acid in abundance. The connexion between our daily bread and the functioning of the brain has recently been brought into the foreground of speculation by Mellanby's experiments with dogs.<sup>2</sup> Feed-

ing dogs of the same litter at one time on untreated flour, and at another time on flour commercially bleached and "improved" by nitrogen trichloride, he found that dogs fed on the improved flour developed canine hysteria, from which they remained free while on a diet of untreated flour. It is at least possible that it was the glutamic acid of the flour gluten which had been chemically altered and made toxic.

In the United States interest in these questions was first focused on the feeding of glutamic acid to rats, from which it was found that their powers of maze learning were improved. Zimmerman, Burgemeister, and Putnam<sup>3</sup> have now reported an experiment in which glutamic acid was fed to nine children of whom seven were epileptic and two mentally retarded. Their ages ranged from 16 months to 17 years. Sufficient glutamic acid was given to produce a noticeable increase in motor activity, the dose varying from 6 to 24 grammes a day by mouth; this dosage was maintained for six months. The children were investigated before and at the end of this period by intelligence tests. In every one of the epileptic children there was clinical improvement, five of the seven ceasing to have fits; but treatment by phenobarbitone and other drugs had been continued, and the improvement cannot be attributed with any certainty to the glutamic acid. Apart from the two youngest children, aged 16 months and 2 years, both of whom were seriously retarded, all the remaining children showed a greater improvement in intelligence than could be expected from lapse of time alone. There were improvements in the intelligence quotient of from 5 to 13 points with an average of 9. The question arises whether these improvements could be accounted for by the great reduction in the severity of the epileptic fits. After discussing the literature and the results in a control group of epileptic children under treatment but not with glutamic acid the authors conclude that their findings cannot be explained in this way. They also believe that the practice effect of re-testing is negligible in their experimental group. Though the smallness of the experimental group imposes caution they conclude that glutamic acid may have a genuine facilitating effect on mental functioning in human subject as it does in rats.

It is perhaps permissible to speculate whether these improvements in intelligence were due not to a direct action of the extra glutamic acid but to its protective action against the subclinical ill-effects of the children's normal diet of bread made from treated flour.

### COAGULATION TIME AND ANTIBIOTICS

Apart from allergic manifestations there have been few records of any serious reactions resulting from the repeated administration of penicillin. There is, however, considerable evidence to show that both penicillin and streptomycin may produce changes in the coagulation time of the blood. In 1943 Moldavsky, Hasselbrook, and Cateno<sup>4</sup> found this in patients under treatment with penicillin the clotting time was materially shortened after an injection. These observations have been confirmed by Macht and Ostro,<sup>5</sup> who observed also that when injections of penicillin were given to two patients suffering from haemophilia no shortening of the coagulation time resulted.

The specimens of penicillin on which the original observations were made were probably impure. The whole question has therefore been investigated again by Macht With amorphous penicillin of a dozen or more brands

<sup>1</sup> *Amer. J. med. Sci.*, 1946, 211, 448.

<sup>2</sup> *British Medical Journal*, 1946, 2, 885.

<sup>3</sup> *Arch. Neurol. Psychiat.*, Chicago, 1946, 56, 489.

<sup>4</sup> *Science*, 1945, 102, 38.

<sup>5</sup> *Ibid.*, 1946, 103, 402.

<sup>6</sup> *Ibid.*, 1947, 105, 313.

marked acceleration of clotting time was found both in man and in animals. The increase in the time of clotting was usually noted within fifteen to twenty minutes of the injection but was often most pronounced about one hour later; the effect persisted for several hours in every case. The route of administration appeared to make little difference; the reduction in clotting time was noted after intravenous or intramuscular injection and when the penicillin was given by stomach tube. With a highly purified sodium salt, consisting almost entirely of penicillin G, the thromboplastic effect was much less striking. Relatively pure specimens of the four penicillins were then studied. Penicillin X (hydroxybenzyl penicillin) was found to be the most active in reducing the coagulation time; then came K (heptyl penicillin), F (pentyl penicillin), and G (benzyl penicillin). A curious finding was that the addition of a small dose of penicillin X to penicillin G apparently had a synergistic effect, producing an increase in coagulation time far greater than that following a much larger dose of penicillin G alone. Streptomycin, too, has the effect of increasing the coagulation time of the blood in cats and rabbits. In rabbits which had received a number of injections of penicillin the coagulation time of the blood remained shortened for a considerable period, so that fresh experimental animals had to be employed. Both in rabbits and cats the thromboplastic action of penicillin can be overcome by suitable doses of dicoumarol.

Since nature has provided generous checks and balances to the higher animals, as well as compensatory and reserve faculties, the danger of thrombosis in clinical practice is probably small. Nevertheless such cases are already being recorded. Frada<sup>7</sup> described in four patients embolic accidents which he attributed—in the light of recent findings probably correctly—to the action of penicillin in increasing the coagulability of the blood.

### CRIMINAL LAW IN THE NEW ORDER

As society evolves, the law is one of the last institutions to change. Criminal law changes even more slowly than other branches. This fact is likely to prove extremely important in the near future, and unless conscious and successful efforts are made to bring our criminal law into line with present-day fact and sentiment the existing disrespect for all law, already dangerous, may increase to a disastrous extent. The treatment of the criminal has received a good deal of attention during the last fifty years; the criminal law itself has hardly been touched. As set out in his recent book,<sup>8</sup> Dr. Mannheim's thesis—and it seems self-evident—is that before we begin to consider how convicted law-breakers should be treated an analysis should be made of those actions of which a prison sentence or a probation order may be the legal consequence. The criminal law, unless it is to lose its meaning, must reflect more or less faithfully the fundamental values on which contemporary society rests. Dr. Mannheim's idea is therefore to consider the repercussions on the criminal law which have been produced by the present crisis in values, and the practical consequences which must flow from them. He points out that in any attempt to reconstruct criminal law two basic problems must be faced: those of defining the most important values of the present world, and of deciding whether those values should be protected by the criminal law or by some other agency. This investigation has led him over a very wide field and into a number of paths which at first sight seem to have little connexion with criminal law. His first section, on the

protection of human life, considers first the individualistic aspect, under the headings of homicide, suicide, and euthanasia; and then the collective aspect, including birth control, abortion, and the extermination of the socially useless or restriction of their reproduction. Under the protection of sexual and family life he ranges over the field of sexual offences and offences against the family. He then deals with the even larger subject of economic crime, which has undergone much more rapid change than has crime against persons. He criticizes the traditional approach to the protection of property and sketches what he considers the necessary new approach. In his study of offences against property (usury, profiteering, fraud against the revenue, monopoly), and of protection of and against labour (strikes and absenteeism), he is even less conventional. Having surveyed present values, he makes a series of recommendations which have already found wide support but of the fulfilment of which there is at present no prospect: they include the abolition of punishment for suicide, the legalization of euthanasia, the introduction of degrees in murder, the legalization (within limits) of sterilization and abortion, and many other controversial suggestions.

In the second half of his book Dr. Mannheim draws up a blueprint for the criminal justice of the future, with a view to making it more scientific and more democratic, and to introducing more international co-operation and more planning. Briefly, he advocates a more modern type of legal draftsmanship; greater facilities for permanent observation of the working, and frequent improvement in the wording, of law; and better integration of the work of experts in criminal cases. He would have a "treatment tribunal" to advise the courts before a prison sentence is passed: he would prohibit short sentences and extend the scope of the indeterminate sentence. He would set up summary courts with a stipendiary chairman and lay assessors; he would abolish trial by jury except in political cases. Naturally, he advocates the extension of legal aid for defendants. He wrote before the publication of the Rushcliffe report but broadly agrees with its findings. He calls for a comprehensive planning programme to co-ordinate all the interested agencies, public and private. This is a profoundly interesting and imaginative piece of social research by a highly experienced and qualified expert, and deserves a prominent place in the attention of reformers.

### HONORARY PHYSICIANS TO THE KING

The following have been appointed Honorary Physicians to the King for a period of three years: Dr. James Boyd, F.R.C.P.I., Chief Medical Officer, Ministry of Health and Local Government and Ministry of Labour, Northern Ireland; Sir William Allen Daley, M.D., F.R.C.P., Medical Officer of Health and School Medical Officer, London County Council; Dr. Alexander Mackenzie Fraser, Medical Officer of Health of the Burgh and County of Inverness (Highlands and Islands Medical Service); Sir Walter Haward, O.B.E., M.B., B.S., Director-General of Medical Services, Ministry of Pensions; Sir William Wilson Jameson, K.C.B., M.D., F.R.C.P., F.R.C.O.G., Chief Medical Officer, Ministry of Health and Ministry of Education; and Dr. Norman Tattersall, Principal Medical Officer, Welsh National Memorial Association, Cathays Park, Cardiff. The following have now completed their term of office as Honorary Physicians to the King: Dr. J. A. Charles, F.R.C.P., Sir Andrew Davidson, M.D. Glas., F.R.C.P.Ed., Dr. H. M. C. Macaulay, Dr. E. R. A. Merewether, F.R.C.P., Dr. W. Rees Thomas, F.R.C.P., and Prof. G. S. Wilson, F.R.C.P.

## A.M.A. CENTENARY EXHIBITS AND PAPERS

A general account of the Centenary Meeting of the A.M.A. has already been given in leading articles in the *Journal* of June 7 and 28, and in the former issue appeared an article on the history of the A.M.A. by Dr. Morris Fishbein, Editor of the *Journal of the American Medical Association*. We print below a summary of the proceedings of the meeting. In the space available it is possible to refer to only a few of the many interesting exhibits and papers. Eighteen different sections were holding simultaneous meetings; the House of Delegates was conducting its business at the same time; and on top of this there were the superb scientific exhibits to visit.

### Scientific Exhibits

The scientific exhibits were assembled under the general direction of Dr. Thomas G. Hull in the Convention Hall in Atlantic City—the largest hall for this purpose in the U.S.A. The general layout of the exhibits was similar to that of some of those housed in the Wellcome Museum. Each consisted of a booth whose back and side walls were used for the exhibition of charts, diagrams, maps, x-ray films, photographs, mounted specimens, and anatomical models. Pamphlets describing the work of the exhibits were obtainable, and the exhibitors themselves were on duty most of the day to demonstrate and discuss the work shown.

The majority of the exhibits were competitive. A gold and a silver medal and other awards were given for two classes of entry. Drs. George E. Burch and Paul Reaser, of the Tulane Medical School, New Orleans, won the gold medal for original work with their exhibit entitled "Radio Elements and Mechanism of Congestive Heart Failure: Radiosodium ( $\text{Na}^{24}$  and  $\text{Na}^{22}$ ). This work showed that in patients with congestive heart failure "there was a much more prolonged retention of sodium than in the normal subject." The awards in the second group were for exhibits which "do not exemplify purely experimental studies but are judged on the basis of excellence of correlating facts and in their presentation." The gold medal in this case went to Drs. George F. Cahill and Meyer M. Melicow, of the Squier Urological Clinic, Presbyterian Hospital, New York, for the exhibit on tumours of the adrenal gland.

In addition to entries falling into these two groups the committee sponsored four special exhibits: on cardiovascular diseases, fractures, fresh pathological material, and physical medicine. The cardiovascular exhibit under the guidance of Paul Dudley White, of Boston, covered an amazingly wide range, and included a fine selection of historical works on the heart and the circulation. Under the chairmanship of Kellogg Speed, of Chicago, the fracture exhibit was accompanied by continuous demonstrations throughout the week; in order to make this possible no fewer than thirty orthopaedic surgeons assisted the committee.

A group of workers from the University of Minnesota presented an interesting exhibit on the physiological problems of bulbar poliomyelitis. The epidemic of last year, the largest since 1916, attacked 25,191 persons throughout the U.S.A. There were 2,875 cases in Minnesota alone, and the exhibit was based on the experience obtained in treating 183 patients suffering from bulbar poliomyelitis, classified by the Minnesota group thus: (1) *Cranial Nerve Nuclei Type*, with the symptom of difficulty in swallowing. (2) *Respiratory Centre Type*, with deficient oxygenation of the blood. (3) *Circulatory Centre Type*, with changes in pulse rate, rapid fall of blood pressure, and the general symptoms of shock. (4) *Encephalitic Type*. "Many patients with involvement of the bulb of the brain show signs of confusion, apprehension, and anxiety. These symptoms are chiefly due to the lack of oxygen in the brain. Only rarely is there actually virus infection of the cortex of the brain producing these typical encephalitic symptoms." (5) *Bulbar-cervical Spinal Type*. Patients have a mixture of the above symptoms and also may show paralysis of the muscles of respiration. Treatment includes nasal tube feeding, tracheotomy, and oxygen therapy. The exhibit included the oximeter—an electronic device which, clipped on the patient's

ear, immediately records the amount of oxygen circulating in the blood stream.

Another exhibit on poliomyelitis was presented by the National Foundation for Infantile Paralysis. With modern methods of treatment, it was stated, approximately 50% of cases of poliomyelitis recover completely; approximately 20% suffer severe and another 20% mild paralysis; the mortality rate is 5-10%. According to maps showing the distribution of poliomyelitis throughout the world, the first sizable European epidemic appeared in Norway and Sweden in 1905; the first sizable epidemic in the U.S.A. occurred in New York City in 1907. Severe epidemics did not arise in Japan until 1938 and 1940.

Before leaving the subject of these exhibits some mention must be made of the motion pictures. The scope and variety of these can best be suggested by the fact that three theatres were in continuous operation, and each was showing something in the neighbourhood of twenty films a day.

The enormous size of the Convention Hall (its floor space would engulf St. Paul's Churchyard), and the equally enormous wealth of many of the firms exhibiting, combined with the native American flair for advertising, produce an impression of colour and luxury which would be startling, even shocking to post-war English eyes. It is of course impossible to know the total amount of money spent to produce these stands; but unofficial estimates varied between three and five million dollars.

One firm demonstrated the advances in a century of anaesthesia by means of a mechanical puppet show, complete with drop curtains and instrumental overture. The curtain goes up upon an operating theatre where an anaesthetist explains the progress of anaesthesia to one of the original A.M.A. delegates who has returned to this world for a brief look round. The demonstration is remarkably complete, even to the movement of the puppet's arms, head, and lips; and the lecture is illustrated upon a miniature screen. The manufacturers state that it is "the expressed opinion of many of the visiting surgeons that this exhibit is a museum piece." It seems fair comment.

### Summaries of Papers

#### NITROGEN MUSTARDS

Drs. Leon O. Jacobson and Charles L. Spurr, of the University of Chicago, read a paper on nitrogen mustards in the treatment of disease. Developed originally as poison gases, nitrogen mustards have been used with encouraging results in the treatment of Hodgkin's disease. Fever, pruritus, and malaise are frequently relieved within a few days of treatment, and there is slow regression in the size of the liver and spleen and of the enlarged lymph glands. Nitrogen mustards, according to Drs. Jacobson and Spurr, have produced significant clinical remissions in Hodgkin's disease, lymphosarcoma, chronic lymphatic leukaemia, chronic myelogenous leukaemia, and in polycythaemia rubra. The drug was without effect in acute leukaemia and multiple myeloma.

#### CANCER OF THE STOMACH

Dr. Owen H. Wangensteen, of Minneapolis, observed that (1) cancer of the stomach was the most frequent of all malignant diseases; (2) that the death rate from it was high in almost all countries, comprising 25-40% of all deaths from cancer; (3) that in the U.S.A. cancer as a cause of death ranked next to heart disease and that of the 150,000 annual deaths from cancer approximately 40,000 resulted from cancer of the stomach; (4) that at present the only worthwhile treatment was surgery. Many patients with cancer of the stomach were inoperable when they first consulted the physician: only 25% were "suitable candidates for a curative type of operation." Dr. Wangensteen considered the problem was to persuade all men and women who had reached the "cancer years" to undergo periodic examination. Figures indicated that one woman out of every five past 40 years of age would die of cancer and one man out of every six past 50. He urged the setting up of cancer detection clinics at strategic places manned by competent specialists in the various branches of medicine and surgery.

## VIRUS DISEASES

Dr. Edwin W. Schultz, Professor of Bacteriology at Stanford University, California, said that viruses had a wide variety of hosts. The discovery by Dr. E. W. Goodpasture that the developing egg could be used as a growth medium for viruses was a milestone in the study of these organisms. Also of great importance was the electron microscope and the use of colloid filters for classifying viruses according to size. The difficulty of treating virus disease in man lay in the fact that a virus particle, once lodged in a cell, was apparently out of reach of drugs which might be carried by the blood stream, while antibodies were too large to follow the virus into the cell. "Recently reported results following administration of sulphonamides and penicillin in certain individual virus and rickettsial infections suggest that such an approach may not be entirely out of the question," he said. Effective immunization against many virus diseases seemed to require the use of active virus, but strains safe enough for use as vaccines were few in number. Vaccine virus, fixed rabies virus, and strain 17D yellow-fever virus were three outstanding examples.

In a paper on the electron microscope Dr. Ralph W. G. Wyckoff said that magnification by as much as 100,000 times could be obtained. "The largest viruses have distinctive shapes. Some are brick-like, like the poxes. Some bacteriophages are sperm-like with heads that show characteristic internal structures and tails whose appearance depends on the strain. All the very small animal viruses and most of the plant viruses thus far photographed are spherical or nearly spherical particles."

## IDIOSYNCRASY TO DRUGS

Dr. Carl A. Dragstedt, of Northwestern University Medical School, Chicago, in a paper read before the Section on Experimental Medicine and Therapeutics, said that idiosyncrasy to certain drugs represented one of the most challenging of all problems in medicinal therapeutics. There was no satisfactory explanation as to why some people became allergic to certain drugs and some people did not. "Experience has taught us that idiosyncrasies to aspirin, aminopyrine, the organic arsenicals, the sulphonamides, thiouracil, quinine, and many others, are considerably more frequent than to alcohol, amphetamine, cascara, chloral hydrate, digitalis, and the like; but there is little ground for any generalization that would have prophetic value as to the potentiality of idiosyncrasy for a hitherto unknown drug."

## X RAYS AND WOUND INFECTION

Dr. James F. Kelly, of the Creighton University School of Medicine, considered there was no justifiable reason for not using x-ray irradiation for the prevention and treatment of wound infection. It was simple, and cost little. The dangers from such application of the rays were less than the dangers associated with many other forms of prophylaxis or therapy. The application of x rays in acute infection was followed by favourable clinical reactions—decrease of pain, localization of the infection, conservation of tissue, prevention of secondary infections, and shortening of the course of the disease. He claimed that x rays had proved very effective in the treatment of gas gangrene: in a group of 46 cases treated by x rays but receiving no serum the mortality was 4.34%.

## PEPTIC ULCER

Sir Heneage Ogilvie, reviewing the treatment of peptic ulcer, observed that "whatever we wish to believe regarding stomach ulcers, we can find evidence in experimental work to prove theory." The only factor on which there was unanimity of opinion was the part played by hydrochloric acid. Peptic ulcers were common where hydrochloric was high, rare where it was low, and unknown where it was absent. It had been estimated that in the U.S.A. 6,500,000 persons suffer from peptic ulcer.

Dr. Samuel F. Marshall, of the Lahey Clinic, Boston, said that over a 10-year period there had been in his clinic approximately 8,000 peptic ulcers with a ratio of 10 duodenal ulcers to one gastric. He urged that operation should be performed whenever a diagnosis of gastric ulcer was in doubt. "We believe that all patients with chronic or recurring gastric ulcers

should be operated on without delay because of the considerable percentage of diagnostic error and because resection can be done with so great a margin of safety." Early recognition of cancer of the stomach presented a challenge to the medical profession, because in many cases the diagnosis was made too late.

Dr. Maurice Feldman, of Baltimore, in a paper entitled "A Statistical Study of the Life Cycle of 1,154 Cases of Duodenal Ulcer," stated that although the cause was still debatable there was no doubt about the association of psychogenic factors. In the majority of cases of duodenal ulcer symptoms began between the ages of 20 and 35.

The psychogenic factor in peptic ulcer was stressed by Drs. Jurgen Ruesch and Karl M. Bowman in a paper on personality and chronic illness. "We have been able to show," they stated, "that in chronic disease in general, in duodenal ulcers, and in thyroid patients, there is an unusual number of social climbers and strainers. . . . In ulcer and thyroid patients in particular there was an unusual incidence of foreign-born and native-born persons of foreign parentage. This fact would indicate that culture change and the resulting conflict of values were a source of stress and strain in these patients."

## PSYCHOTHERAPY IN PRACTICE

The importance of psychotherapy in general practice was emphasized in papers read by Dr. Edward Weiss, of Philadelphia, and by Dr. Walter C. Alvarez, of the Mayo Clinic. Dr. Weiss defined psychosomatic medicine as "the simultaneous application of a study of the patient's mental and physical life." Although "psychosomatic" was a new term it described an approach to medicine as old as the art of healing itself. "In our elaborate medical institutions," Dr. Weiss observed, "with a lack of knowledge of the patient's background, we over-emphasize the so-called scientific aspects of medicine and relegate to the background the social and emotional factors that may enter into illness. As a consequence our methods of taking a patient's medical and personal history have not kept pace with general progress in medical science." He emphasized the value of the service given by "the old family doctor" who "relied heavily on psychosomatic techniques even if he didn't know it." He urged that the doctor intending to go into general practice should have more training in psychiatry.

## LIQUID OXYGEN

The use of liquid oxygen in skin disease was discussed in a paper read by Drs. Roy L. Kile and Ashton L. Welsh. Liquid oxygen was applied by cotton wrapped around a wood applicator. Liquid oxygen was inexpensive and, with reasonable care, safe to use. It was easier to handle than was carbon dioxide. Liquid oxygen was so cold that the lesion rapidly turned white. A thorough freezing of the lesion occurred in a few seconds. With it they had treated warts, haemangiomas, leucoplakia, seborrhoeic and senile types of keratosis.

## LONGEVITY AND MORTALITY OF AMERICAN DOCTORS

A preliminary report on the longevity and mortality of American physicians from 1938-42 was made by Dr. Louis I. Dublin and Mr. Mortimer Spiegelman, of the Metropolitan Life Insurance Company. According to these two statisticians the average young physician entering the profession at the age of 25 has 43½ years of life in front of him. On reaching the age of 35 the physician on an average has almost as many years remaining as he has already lived. At the age of 45 he may expect a further 25 years of life. "Almost 12 additional years of life remain to the average physician attaining the age of 65, a frequent age for retirement."

The insurance company's study is based on records of living physicians and on the deaths of active and retired physicians for the period 1938-42. The general conclusion was that "physicians experience practically the same longevity and mortality as white males of the same ages in the general population." Knowledge of hazards to health give physicians an advantage. "Evidence in this direction is found in the favourable mortality for most infectious diseases and surgical conditions and from accidents. The death rate from tuberculosis among male physicians is less than half that of white males of the same ages in the general population; for syphilis the ratio

is only one-third. The death rate from cancer among male physicians is four-fifths of that for white males of the same ages; in the case of appendicitis, hernia, and intestinal obstruction the ratio is three-quarters. . . . These advantages are offset by a relatively high mortality from the cardiovascular conditions. In particular the recorded death rate from diseases of the coronary arteries among male physicians is  $1\frac{1}{2}$  times that of white males of the same ages in the general population." Mortality from leukaemia among male physicians was found to be  $1\frac{1}{2}$  times that of white males generally. Dr. Dublin and Mr. Spiegelman repeated the opinion recently expressed that physicians may have acquired the disease as a result of exposure to x rays. "Far outstanding on the mortality list are diseases of the heart and coronary arteries, with 40.7% of the total deaths."

## CANCER DETECTION IN AMERICA

[FROM A CORRESPONDENT]

The very high proportion of cases of malignant disease which are inoperable when seen for the first time in a hospital outpatient department is surely a challenge to the medical profession, whose responsibility it is to take all possible steps to improve this state of affairs. In the United States of America this challenge has been accepted and an attempt is being made in many parts of the country to extend the principles of preventive medicine to the control of cancer.

There are two complementary efforts: first, an educational campaign to bring to the notice of the public the early signs and symptoms of the more commonly occurring types of cancer; secondly, the provision of clinics at which people whose interest has been aroused may be given a thorough examination. The object of the publicity campaign is not only to persuade people who have signs or symptoms suggestive of malignant disease to seek immediate medical advice, but equally to persuade apparently healthy people to undergo periodic physical examinations as the best means of achieving early diagnosis and treatment of malignant lesions. The clinics are usually known as Cancer Detection or Prevention Clinics, and are held at fully equipped general hospitals which provide radiological and laboratory services and, most important of all, well-trained clinicians. They are in most instances run quite separately from the established tumour diagnostic clinics in order to encourage regular visits from normal or presumably normal individuals.

Before the patient, after a detailed clinical history has been obtained, is given a complete physical examination which includes the mouth and nose, the rectum, and in women patients the vagina. Laboratory tests such as a urine examination, a complete blood count, and a Wassermann reaction are routine. X-ray examinations are carried out whenever the slightest symptom suggests their need, and in many clinics it is hoped to make an x-ray examination of the chest and alimentary tract a routine when wartime shortages of material and staff have been overcome. The clinics do not undertake treatment; if the examination reveals a malignant lesion or some constitutional disease the patient is referred with a full report to his medical practitioner or, if he so prefers, to the proper department of the hospital. Patients in whom no malignant lesion is discovered are instructed to return for re-examination in from six to twelve months or earlier if any unusual symptom appears.

### Results of the Scheme

The success of the publicity campaign is shown in the published figures of the patients attending the Strang Cancer Prevention Clinic at the Memorial Hospital, New York: 40% were referred from the New York City Cancer Committee, 30% through various types of publicity such as lectures or demonstrations, 16% were referred by former patients, and 10% came from the Memorial Hospital clinics. From the medical point of view the results of the experiment are equally encouraging. It was found that out of a total of 1,103 cases attending the Strang Cancer Prevention Clinic 7% had malignant tumours. In the group of patients reporting without symptoms and apparently healthy 1% were discovered to have malignant tumours. A considerable proportion were found to have other

diseases which required treatment. Dr. L'Esperance, Director of the Strang Clinics, insists, not without reason, that in discovering unsuspected lesions such as rectal adenomata and cervical tears and erosions the clinics are helping to prevent the development of cancer. These clinics are now well established in the public esteem and they have received the official blessing of the American Cancer Committee. In New York the medical students at the Cornell Medical Centre attend the Cancer Prevention Clinic at the Memorial Hospital as part of their studies in preventive medicine.

These are the bare facts. Armchair criticism may be levelled at many aspects of the scheme, but it cannot be denied that essentially the scheme provides the only way in which the medical profession can hope to discover an increasing proportion of cases of malignant disease at a stage in which a cure is not only possible but probable. It may be rather terrifying to contemplate the snowball growth of these clinics, but in return we may hope for an increasing number of patients who have been cured of cancer and are not afraid to tell their friends about it.

## RADIOTHERAPY OF CANCER

Radiotherapy centres are still suffering from the dislocation caused by the war and from uncertainty as to future developments under the National Health Service Act. The National Radium Commission in its report<sup>1</sup> for 1945-6 urges strongly that in every region there should be a cancer organization, under the regional hospital board, to provide facilities for early diagnosis readily available to every general practitioner, and for immediate treatment planned and carried out by experienced specialists. Every patient suffering from cancer, whether seen in the early stage or in the late stages of the disease, should be followed up at intervals until death from whatever cause.

The report points out that these regional cancer services should not be difficult to set up as the Commission had such schemes in view from its inception. Some regional planning has been done already in the areas where national or regional radium centres exist, namely, Birmingham, Bristol, Bradford, Cambridge, Cardiff, Leeds, Liverpool, Manchester, Newcastle, Sheffield, and Southampton. For other parts of the country it will be more difficult because of the scarcity of specialists and the difficulty of persuading some surgeons "to abandon the present haphazard method by which one surgeon tries to deal with a great variety of types of cancer."

The Commission has paid special attention to the position of the general practitioner in such a service and to local organization designed to facilitate early diagnosis. The British Empire Cancer Campaign has been asked to arrange for lectures to general practitioners. The record cards which have always been insisted on as a condition for the loan of national radium have now been taken over by the General Register Office at Somerset House.

The report contains short summaries of annual reports from most of the centres connected with the National Radium Commission. If these are compared year by year it will be seen that the Commission has had a profound influence on local organizations for the diagnosis and treatment of cancer, the good effect of which is just becoming obvious.

<sup>1</sup> *Seventeenth Annual Report of the National Radium Trust and Radium Commission.* Cmd. 7127. H.M.S.O., London. 6d.

*Diabetes: A Concise Presentation.* By Henry J. John, M.D., F.A.C.P. (Pp. 300; illustrated. 17s.) London: Henry Kimpton. 1946. Consisting of a series of papers on diabetes, this book will not satisfy the student seeking a clinical description of the disease, for symptoms are regarded as belonging to the pre-insulin era, and retinitis, a complication seen only too often in patients having the best modern treatment, is not mentioned. The calculations necessary for the generous diets advocated are too complex for use in countries where food is rationed and leisure small, and the author does not describe recent work on carbohydrate metabolism. Though his observations—based on wide experience—are interesting, this book cannot be classed with standard works on the subject. However, he discusses with homely wisdom the special problems of the diabetic patient, and is at his best in writing of the diabetic child.

## Nova et Vetera

### AMATEUR BODY SNATCHERS

William Merritt Hartlebury Day, M.D., qualified at St. Peter's Hospital, Bristol, and was a student there from 1834 to 1841. Dr. Day was surgeon at Wells County Asylum in 1850 and later medical superintendent at Stapleton (Bristol) Asylum. He died on Aug. 9, 1871. Recently his granddaughter, Miss Kathleen Tuttle (Director of Music at Howell's School, Denbigh, N. Wales), sent us a manuscript in his handwriting. This is signed "W. M. H. D." and dated March 10, 1835. It is given in full below and has been altered only by punctuating and paragraphing.

#### A Visit to the Tombs

Being one evening in a pensive and thoughtful mood with nothing to do I sat me down with a determination of writing the particulars of my first visit to the tombs. My fellow apprentice and myself having determined upon having a subject for dissection we accordingly prepared for our adventure, which with ourselves a friend and a man we hired to dig we proceeded. Having got every thing that our share required—I mean tools, spade, sack, etc., and with two bottles of shrub and a small stick—we thought ourselves a match for any charley or charleys that by chance we should happen to meet. So having a good tuck in and plenty of strong beer we thought about 11 o'clock time to start, so off we sallied to the churchyard merry and not fainthearted. But I, unlucky fellow as I always was, and so will be till the end of my days, lost the cork of one of our grog bottles, which occasioned us to drink it on our passage. We all arrived without further interruption to the churchyard, when we waited close by in a convenient place while one of our company proceeded to the churchyard and having looked about him and seeing all was favourable he came back and we all sallied in together. The man then commenced digging, I and another was watching at a distance and the other was waiting by the mau to help him when he wanted help.

Soon after our arrival a shower of mist began to fall which greatly favoured our work. I felt myself quite warm and without any dread or feeling in the place I was in. I walked about when it was time to watch with the greatest composure. The clock struck 12 and we all stepped back to the hedge and waited. I forgot to state that there was a path through the churchyard which the watchman had to walk through in going his round every half hour. So you must think it was bold proceeding for four young chaps who was never out before nor had an idea as to the manner in which such work was performed. So waiting nearly half an hour for the watchman the man then began to swear and said he would not wait any longer, so he accordingly went to the grave which was by the footpath and recommenced digging.

The clock struck one, two, then three. No hopes of finding anything like a coffin. The grave was two feet deep in water. The man then began to swear in a horrid manner and said he would not go on, but at last with frequent tips at the shrub bottle and doing a bit now and then ourselves got the better of him. We at last came to a coffin, which to our great disappointment was a child's; it had intact coverings with a silver edge to it. We accordingly commenced lift the lid, which we found was like a bit of soaked leather, resisted the chisels and every effort which we tried to move it. We accordingly after a long time made a small opening, which with our hands we tore bit after bit till at last we made an aperture big enough to pull the little dog through; he looked more like a drowned rat when I got hold of him to pull him out of the grave. I accordingly put him in the sack and we recommenced the business of filling up the grave.

There was a watchbox adjoining the wall of the churchyard, in which two watchmen. One of our company went up to the watchbox to listen if he could hear the men digging, which he said he could quite plain. While he was standing there two cats jump upon the wall and commenced caterwauling in a dreadful

manner, which made him run off. During the time we was there the weathercock kept veering round with a terrible noise as if angry at our proceedings. After we had put the subject in the bag we commenced filling the grave, which the time we was there, the time of the morning, and the disappointment we had felt in not finding a full-grown subject, after we half filled the grave we determined upon leaving the grave half filled up and returning home. We got all our things in order and left the churchyard, and as we got outside the gate, the man carrying the body and I last with the spade, to our utter astonishment and terror we beheld two watchmen standing staring us in the face, but they, although they must have seen us as plain as I see the paper I am now writing upon, never offered to move. We expected to hear them spring their rattles every minute; we accordingly without further interruption proceeded homewards, and when we arrived the person that was to wait up for us that went to sleep and we accordingly, because we should not make too much noise as the watchmen were going their rounds, we placed the body in the niche of our door and the spade in another. We placed our backs against the door and in it went. We brought in the body and things and found it was six o'clock. So we had been five hours in the churchyard.

About eight o'clock I and the man and my fellow apprentice proceeded homewards with the body, which we had in a sack, the people staring at us as we went along the street. We left the man about half way and we went ourselves with the body; the shops were by this time opened and the business of the day had begun. We were covered from head to foot with churchyard dirt, which made us looked very suspicious; every person that passed staring at us well as much as if they suspected we were murderers. When we arrived home no one was up and we had to wait till we had knocked them up. Our fears had not ended then, for by the time we had arrived a dog was took ill with convulsions and began moaning in a dreadful manner and a crowd soon collected round the door, which looked more at us than at the dog. I should have done the same myself seeing two young fellows standing at a surgeon's door with a sack on their back covered with red mud from head to foot looked damned suspicious. At last the door was opened and went in with our sack. Thus ended my first visit to the tombs.

March 10, 1835.

W. M. H. D.

## Preparations and Appliances

### PNEUMATIC BONE SAW

A pneumatic bone saw made by Desoutter Brothers Ltd. is now more freely available. This is not a new instrument. It has been used at selected orthopaedic centres for some years, and with increasing experience a number of minor modifications and improvements have been made. Experiments with this

"Mighty Atom" pneumatic bone saw were first undertaken because of the wartime shortage of imported American electrical bone saws. The pneumatic motor used in the instrument is a development of that used in a series of aircraft tools.

All gears and rotating parts are made from chrome-nickel steel, hardened and tempered, and every bearing is a ball or roller bearing. The bone saw is supplied in a wooden case with a 10-ft. length of special high-pressure hose and a quick-coupling unit, chuck key, three stainless steel spindles fitted with stainless steel saws (1 in.,  $1\frac{1}{2}$  in., and  $1\frac{3}{4}$  in. in diameter), and a spanner for changing saw blades. The tool weighs  $1\frac{1}{2}$  lb. and will cut bone grafts with single or double saws. The speed is controlled by a trigger in the pistol-grip handle and the range is from a few rotations to the full speed of 2,000 r.p.m. The saw has to be sterilized by hot air and cannot be boiled or sterilized in the normal steam autoclave. It is worked from compressed-air cylinders with a reducing valve, and a 100 cu. ft. capacity cylinder will give approximately 20 minutes' continuous running—sufficient, that is, for several operations. Over fifty of these instruments have been in use now for a considerable period, and independent orthopaedic surgeons have referred to the pneumatic bone saw as "first-class" and of "proved merit."

## Reports of Societies

### PHYSIOLOGY OF THE BREAST

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on June 20, with Dr. JAMES WYATT in the chair, three papers were read dealing with recent developments in the knowledge of the physiology of the breast.

Dr. S. ENGEL, discussing the anatomy of the female breast in its relation to hormonal response, said that anatomical and histological investigations had been carried out on some 80 breasts in the resting and active stage. In many cases large sections through whole breasts had been used on account of the variations in any single breast. It could be shown that the mammary gland in man differed from that in animals. In animals the breast was filled to capacity with glandular tissue when lactating, whereas in man there occurred many variations, ranging from almost nothing to animal-like abundance. Approximately one-third of the breasts examined had proved to be well equipped; about one-third were below the average, and the remainder showed many transitional stages. Clinical experience of lactating capacity accorded with the anatomical figures.

Badly equipped resting breasts showed primitive and badly differentiated glands. These glands responded poorly or not at all to hormonal stimulus, as could easily be seen in menstruation. Well or less well differentiated glands of the same organ showed different reactions—that was to say, rich sprouting in the first case, and no reaction, or almost none, in the second. This behaviour accounted for the divided opinion on the changes of the resting breast in the menstrual cycle, illustrating the fact that women with well-equipped breasts showed clinical and anatomical changes, whereas others remained indolent. The conclusion was that menstrual changes in the breast might or might not occur. In pregnancy the development depended on the congenital nature of the breast, since hormonal stimulus could not do more than mature what was present in the resting breast. The hormonal treatment of hypogalactic women was therefore limited, for it could only help to bring the mammary gland to its maximal production: it could not convert a poor breast into a good one. Briefly it could be said that the mammary gland in man differed so greatly that its variations had to be taken into account when speaking of hormonal influences. The badly equipped breast would not respond at all, or very little, in menstruation. The presence or absence of clinical symptoms in menstruation would serve to estimate and predict the capacity of lactation in individual cases.

Dr. J. S. FOLLEY said that the first requisite for successful lactation was the existence of adequately developed mammary glands, which presupposed the presence of sufficient histologically normal alveolar tissue. Mammary growth was under the control of the ovarian hormones, oestrogen and progesterone, but it was not possible to make any satisfactory generalization regarding their respective roles in mammary growth, since experiments on various species had revealed striking differences.

To summarize the main experimental findings: it was seen in some species, such as the mouse, rat, and rabbit, that oestrogen alone, in physiological doses, evoked growth of the duct system but little or no alveolar development. In order to produce the latter, combined treatment with progesterone and oestrogen was necessary. In species such as the guinea-pig oestrogen alone was capable of evoking the growth of duct and alveolar tissue alike; it could develop a gland which, under suitable conditions, was able to produce considerable quantities of milk, as shown by the fact that male guinea-pigs in which mammary growth had been brought about by treatment with oestrogen would rear young. The most spectacular results in this category had been obtained in ruminants. In 1938 De Fremery had shown that treatment with natural oestrogens would produce considerable udder development in virgin goats, and it had since been discovered that in the virgin heifer suitable oestrogen treatment would cause the growth of udders capable in many cases of secreting economically important yields of milk. Later experiments done on ovariectomized ruminants indicated that successful results did not depend on the presence of the ovary. In general the response was not quantitatively comparable to a normal lactation, which at once raised the question of whether such experimentally developed glands were normal in structure, and it seemed possible that some additional endocrine stimulus acting in conjunction with the administered oestrogen was necessary for the artificial development of glands capable of yielding amounts of milk such as would be obtained in a normal lactation.

#### "Galactopoiesis"

So far consideration had been confined to the phenomenon which might be described as lactogenesis, or the initiation of lactation. There was an allied but not necessarily identical phenomenon; the stimulation or augmentation of lactation already established, which it had been suggested might be described as galactopoiesis. It seemed probable that the treatment of deficient lactation in women fell under the latter heading, since in most of such cases lactation had been initiated but the milk yield had failed to reach a level necessary for the adequate suckling of the infant. The discovery of the anterior-pituitary lactogenic hormone, prolactin, by Stricker and Grueter in 1928, and its subsequent characterization by Riddle and his collaborators as a pituitary hormone distinct from other pituitary hormones then known, and specific in its ability to cause growth and secretion of the pigeon-crop gland, aroused interest in the possibility of stimulating lactation, particularly in cows and women, by anterior-pituitary extracts. With the development of methods for the partial purification of prolactin there was some tendency to assume that purified prolactin preparations would prove more efficient as galactopoietic agents than unfractionated anterior-pituitary extracts. Extensive experiments on cows, however, had shown that, far from this being the case, unfractionated ox anterior-lobe extracts gave considerably greater galactopoietic responses in cows in declining lactation, for a given unitage of prolactin as measured by the pigeon-crop tests, than partially purified prolactin preparations. With crude saline extracts of ox anterior pituitary substantial though temporary increases in the milk yield of cows in declining lactation could be obtained even in response to single subcutaneous injections. With repeated injections a more sustained, but still temporary, response was obtained.

Finally, there were the effects on lactation of administration of thyroid hormone. The main features of the galactopoietic effect resulting from thyroid treatment might be briefly summarized as follows: The increase in milk yield during the period of treatment was considerable and might amount to as much as 30% above the basal level. Overdosage with thyroid preparations leading to a condition of marked hypermetabolism might, on the other hand, decrease the yield. Most workers have observed, *pari passu* with the enhancement of the milk yield increases in both the fatty and non-fatty fractions of the milk solids; the increase in the non-fatty solids content was at best slight, but the fat content underwent a more marked increase, sometimes to as much as a 50% rise in the daily fat yield.

This work had assumed importance from the point of view of wide-scale practical application in the dairy industry where

it was shown that treatment of certain proteins, such as casein, with iodine under mildly alkaline conditions produced iodoproteins which exhibited thyroid activity by the oral route and from which thyroxine could be isolated after hydrolysis. Since iodocasein could be made quite readily from available materials it was evident that here was a cheap and plentiful supply of artificial thyroid hormone lending itself to easy administration to cows under practical conditions. Large-scale experiments carried out in this country under the aegis of the Agricultural Research Council and in the United States had shown that the galactopoietic effects observed with dried thyroid gland or thyroxine could be reproduced in all essentials by feeding iodoprotein. One important point was that prolonged feeding of doses sufficient to produce milk yield increases of the order of 30% above basal caused sufficient hypermetabolism to bring about significant and undesirable losses in body weight. If, however, one contented oneself with smaller responses the body weight losses were negligible, provided extra food was given in compensation. Clinical reports on the use of thyroid hormones for the stimulation of lactation in women had not always been favourable; in fact, some clinicians had advocated thyroid treatment for the suppression of unwanted milk secretion. Nevertheless, further clinical trials, keeping the necessity for careful control of dosage in mind, would appear to be justified.

#### Vitamins in Human Milk

Mrs. MAWSON and Dr. S. K. KON read a paper on the study of certain vitamins and other constituents of human milk. The investigation described had lasted for more than four years, during which period 2,000 samples of breast milk were examined. Owing to the food policy of the Government some of the changes they had noted had been for the better rather than the worse. They had taken Reading, a prosperous town in an agricultural area, as a starting-point in the early summer of 1941; and in April, 1942, they had obtained support from the Medical Research Council which had enabled them to extend their activities to Shoreditch, thus providing a good contrast. In both areas the husbands of many of the mothers were in the Armed Forces, but Shoreditch had been more subject to enemy attacks than Reading. As a result of the work done confidential reports were sent each year to the Medical Research Council, and from these had followed certain important changes in wartime diet. The difference in the analysis of the milk was most noticeable immediately after the introduction of "national" wholemeal bread and also the first consignments of oranges to reach this country during the war.

Mr. BOURNE mentioned that one of the difficulties that Dr. Kon and Mrs. Mawson had encountered had been to discover women who were sufficiently ill-nourished to provide a really substantial difference in dietary intake compared with those on normal feeding; but there had been one woman found who was grossly undernourished, and it would be interesting to learn what differences were found in the composition of the milk. He had noticed tables on the screen showing the differences between cow's milk and human milk, and he had seen elsewhere attempts to supplement the milk in order to give the child the theoretical optimum. He thought that all such treatment of the natural product was nonsense, and that the more the child had of the natural milk the better it would be. Dr. Kon, in reply, said that with regard to the woman who was grossly undernourished the composition of the milk had been found to be perfectly normal, and it was also found from milk samples in Belgium and Holland taken immediately after liberation that this was usual. They had had to revise their ideas of the effects of starvation and shortage of calories and essential foodstuffs. At such a low level life was geared down so that they could run satisfactorily with a less output of energy.

The Association of British Chemical Manufacturers has issued from 166, Piccadilly, London, W.1, the 1946 edition of its directory *British Chemicals and their Manufacturers*. During the war years the Government forbade publication of new editions and this is the first revision of the directory since 1939. A copy will be sent gratis by the manager of the A.B.C.M. to any inquirer writing on business paper or giving other genuine indication of his being likely to put the directory to good use as a purchaser of chemicals.

## Correspondence

### The Physiology of Vision

SIR.—I have read with great interest the leading article (June 28, p. 932). There are two points which I would like to raise.

In the first place, my doubts concerning the validity of the three-colour theory do not rest entirely on research in which it was necessary to confine the stimulus to single cones or to small clusters of functionally identical cones. Thus one experiment requiring no apparatus, which can be performed by anyone in an ordinary room, consists of taking three little coloured test objects 5-mm. square each—a bright red, a bright green, and a lemon yellow. These are separately mounted in the middle of pieces of black paper about 20 cm. square. If these are examined at a distance of perhaps 5 metres to 10 metres—this distance varies somewhat with the intensity of the light and the personal equation of the observer—it will be found that the yellow test object has altered to pale grey or white, whereas the red one and the green one have retained their colour, with hardly any observable alteration. Now, on the three-colour theory yellow is a mixture of red and green; therefore it would be expected that all the three test objects would undergo changes at about the same distance, but this they do not do. If this experiment be repeated with monochromatic lights produced by a spectroscope a similar result will be obtained.

This was the first experiment that shook my belief in the three-colour theory, to which I had always been a strong adherent.

The second comment concerns Dr. Willmer's book. The writer of the leading article considers that it supports the three-colour theory. A careful examination of this book shows, however, that this is not the case, for it describes an essentially dichromatic hypothesis. This is shown with great clearness if the figures illustrating chapters III and IV are examined. It is true that he states here and there in the book that the dichromatic hypothesis as it stands appears to be inadequate, and that some other factor must be involved of which no account has so far been taken; but in every case he follows it by some such statement as: "There is at least the possibility of overcoming the difficulty under consideration, without immediately assuming the existence of another distinct type of receptor." Thus nowhere in the book can one find anything to suggest that Dr. Willmer wishes to abandon entirely the dichromatic hypothesis which he advances in such detail.—I am, etc.,

London, E.C.1.

H. HARTRIDGE.

### The "Costoclavicular Syndrome"

SIR.—As co-author with Graham Weddell of a paper<sup>1</sup> in which the term "costoclavicular compression" of the subclavian vessels was introduced to the literature, and which is one of the two papers specially mentioned in the text of the recent article in your columns on the "costoclavicular syndrome" by Telford and Mottershead,<sup>2</sup> may I be permitted to forward my comments? I trust you will forgive the delay, but the issue containing this paper has only recently arrived in this country.

Prof. Telford and Mr. Mottershead have rightly stressed that no one mechanical cause can explain all cases of pressure symptoms involving the neurovascular bundle at the base of the neck, and to this view I subscribe. They conclude that under certain circumstances costoclavicular compressions may occur, but in spite of an exceedingly rich experience of cervical rib syndromes they do not appear to have recognized a single example of costoclavicular compression, and consequently leave their readers with a feeling that the syndrome is mere supposition.

Compression of the subclavian artery between the clavicle and an unusually placed first rib has now been seen at operation by a number of observers<sup>3-5</sup> besides ourselves. We described a case with vascular symptoms in which, at operation, proof was forthcoming that the subclavian artery was being compressed intermittently between the clavicle and the first rib, and in which symptoms disappeared completely after this costoclavicular compression had been corrected by removal of a segment of the rib. In addition

we described two other cases, one of which did not require operation, to illustrate other aspects of the mechanism, and also a fourth case with nervous symptoms to show that the mechanism did not operate in all cases with rib-pressure symptoms. Our primary purpose in reporting these cases was to show that the then widely held explanation of the scalenus anticus pressure, and also that of sympathetic dysfunction due to irritation of sympathetic fibres in the lower trunk of the brachial plexus by rib pressure, were not operative in these cases. It is interesting to note that the second of these explanations, which was championed by Prof. Telford on several occasions between 1913 and 1942,<sup>1,2</sup> is not mentioned, either in support or refutation, in his latest article.<sup>3</sup>

Telford and Mottershead quote us that "more than one postural manœuvre involving the shoulder girdle may result in compression of the subclavian vessels," and then in the same paragraph go on to describe the effects on the pulse of depression or downward movement of the shoulder. We, however, had pointed out that "backward and downward bracing of the shoulders is the motion which most directly approximates the clavicle to the first rib," and illustrated the backward mechanism with a line diagram. Nowhere did we describe pure depression of the shoulder. This is important, as Telford and Mottershead take pains to show that pure depression of the shoulder widens the interval between clavicle and rib, although later in their paper they concede that backward movement or retraction of the shoulder may produce clavicular pressure against the scalenus medius. Their movement of retraction had an upward component, however, and if instead a downward component could have been imparted the clavicle would have approximated to the rib. Their findings were based largely on observations in formalinized corpses, and must therefore be accepted with reservation. Only five fresh post-rigor bodies were tested, and, as in another part of their article they showed that retraction of the shoulder only affected the pulses in 60% of living persons, this number of fresh bodies is too few to prove the non-existence of costoclavicular approximation. Their statistics would have been of more worth had they, like ourselves, tested for costoclavicular approximation on the operating table in patients on whom it had previously been shown that retraction of the shoulders obliterated the pulse.

In describing depression of the shoulder Telford and Mottershead point out that, though the pulse in the arm may disappear on depression of the shoulder, a normal pulse remains in the axillary artery well below the clavicle, and that the clavicle consequently has nothing to do with the arrest of the pulse in this manœuvre. This I have confirmed in a few subjects whom I have just tested, but I have noted also that when the shoulders are braced backwards and downwards and the radial pulse disappears even the pulsations in the axillary artery cease. The arrest of the pulse in these two manœuvres, therefore, must be by different mechanisms, and thus the throttling of the brachial artery by the two heads of the median nerve, which Telford and Mottershead describe as occurring in depression or downward movement of the shoulder, is presumably not the responsible mechanism in retraction of backward movement of the shoulder. This latter mechanism we believe to be costoclavicular approximation.

As a cause of symptoms, the costoclavicular mechanism may not be common, at least in the type of case which comes to operation. In our paper Graham, Weddell and I wondered whether it was the usual mechanism in cases of rib pressure where vascular disturbances predominate, as Eden<sup>4</sup> had suggested earlier. Cases of this type with symptoms warranting operation, however, are uncommon, and I have not encountered another case at operation since we wrote our paper. Prof. Telford<sup>5</sup> reported in 1942 that he had collected 4 cases with vascular symptoms out of 92 patients operated on for symptoms of cervical rib, although by 1947 his total appears to have risen to 14 cases out of 120 patients. I have, however, seen a few patients with mild vascular symptoms which I thought were caused by a costoclavicular mechanism, but they improved on exercises designed to brace up the shoulders.

As regards cases of rib pressure with nervous symptoms, I would agree with Telford and Mottershead that the great majority are due to hanging up of the brachial plexus by a cervical rib or other mechanical obstacle, such as a fibrous band or abnormally developed anterior edge of scalenus medius, for such has been my operative experience. It was with some surprise, therefore, that in 1944 I read a paper by Walshe, Jackson, and Wyburn-Mason<sup>6</sup> suggesting that costoclavicular compression was also of frequent occurrence in cases with nervous symptoms. These authors, however, although they described in detail four cases with vascular symptoms, did not support their views regarding plexus compression with case histories. Consequently for some time I have regarded costoclavicular compression of the brachial plexus, in contrast to that of the subclavian vessels,

as a myth, but recently I have encountered a case. This patient, a middle-aged woman, had had for many years generalized plexus symptoms of the type envisaged by Telford and Mottershead, and when the neurovascular bundle was explored at the base of the neck no abnormality other than an undue approximation of the clavicle to the first rib on backward retraction of the shoulder could be made out. The brachial plexus was then compressed between the two structures, and it is significant that symptoms promptly disappeared following resection of a segment of the first rib. It was also interesting to note that a simultaneous compression of the subclavian artery was not present in this particular case, for the planes of the two bones crossed each other obliquely, and the two bones only approached each other sufficiently to compress structures at the place where the plexus passed into the axilla.

I therefore feel that costoclavicular compression of the subclavian vessels or of the brachial plexus as a cause of serious symptoms warranting operation is a real entity, though not a common one. Any surgeon exploring the base of the neck for vascular or nervous symptoms in the arm should always search for the exact spot and mechanism of compression of nerves or blood vessels. If he cannot find an adequate cause in the more usual situations, he should insert the tip of his finger beneath the clavicle opposite the neurovascular bundle, and then by pressing the shoulder backward and downward ascertain whether a costoclavicular compression occurs. If it does the treatment is removal of a portion of the rib. Telford and Mottershead report 5 negative explorations in their series, all without relief of symptoms. Perhaps some of these were costoclavicular compressions.—I am, etc.,

Dunedin, New Zealand.

#### Surgery of the Gall-bladder

SIR.—I am sorry to see an error in your annotation on surgery of the gall-bladder (July 5, p. 21). You state that "partial removal of the gall-bladder, combined with electro-coagulation of the residual strip" is termed diathermy dissection. As stated in my article, this is Thorek's electro-coagulation. Diathermy dissection consists in removal of the whole gall-bladder, which is a simplification of Thorek's operation. I am afraid that anyone who reads the annotation and scans the paper will get a wrong impression.—I am, etc.,

London, W.1.

#### Oxygen Poisoning in Man

SIR.—Sir Leonard Hill's correction (June 21, p. 900) of Dr. Kenneth W. Donald's attribution to the late Prof. J. S. Haldane of certain work on deep diving prompts me to this communication. Dr. Donald writes: "In 1930 the late Dr. J. S. Haldane (Haldane and Priestley, 1935) reported confusion and amnesia in deep-sea air divers at 300 ft. (91.4 m.), and these symptoms were attributed to the raised tension of oxygen. These effects were proved by Behnke *et al.* (1935) to be due to the intoxicant effect of nitrogen at high pressures."

In 1930 I was asked by the Admiralty, through the Medical Research Council, to investigate cases of supposed unconsciousness occurring in divers at 300 ft. They were not presented to me as examples of amnesia. I found the condition occurred in men already subject to unsuspected but distinctly pathological nervous symptoms. One man with severe claustrophobia had been put in a diving suit and sent down to 300 ft. By using the then unfashionable method of revival and abreaction it was shown that what the men described as unconsciousness was a state of pathological terror, the memory of which had been suppressed. The simple technique and its dramatic results were described to my colleague Surgeon Lieutenant-Commander A. E. Phillips (*Proc. roy. Soc. Med.*, 1932, 25, 693) and by myself (*Ibid.*, 1933, 26, 655). In my

## Towards more normal control

One injection of Globin Insulin (with Zinc) before breakfast controls the blood sugar throughout the twenty-four hours in the majority of mild and moderately severe diabetics. Globin Insulin is a further step towards the ideal — the normal control of blood sugar.

'Wellcome' <sup>WELL</sup> Globin Insulin (with Zinc) 40 and 80 units per c.c., each strength in phials of 5 c.c. Descriptive literature available on request.

\* Originated and developed at The Wellcome Research Laboratories, Tuckahoe, New York

## ACID MILKS IN INFANT FEEDING

The wealth of buffer substances in milk results in the absorption of considerable quantities of acid in the digestive tract. In certain cases it is reasonable to give the infant the kind of nourishment which necessitates the least effort, and controlled acidification offers a means of reducing demands on the secretory functions. In view of the varied nutritional needs of infants requiring acid milk; the following range of products is available:—

### BEURLAC

A buttermilk in powder form, useful for infants suffering from gastric disorders.

### PROLAC

Of approximate half cream fat standard, but with increased protein, as required in gastro-enteritis.

### LACIDAC

#### HALF CREAM

An intermediate grade for less severe cases and for graduation to normal feeding.

#### FULL CREAM

Suitable for long term use, or as a final stage of graduation to normal feeding.

### SEPARATED

Almost fat free. Invaluable in cases of fat intolerance.

★ Particulars of these and other Cow & Gate preparations for specialised infant feeding will be gladly forwarded on request.

*Athlete's foot*, *'Swimmer's Itch'* ... these descriptive names return forcibly to the vocabulary at this time of year. Increased facilities for communal exercise bring increased prevalence of fungus skin infections in one form or another, together with the problem of how best the individual case can be relieved and how threatened outbreaks in schools, sports clubs, swimming pools and other public

centres can be halted. 'Mersagel' is designed specifically to deal with this problem. It incorporates the powerful fungicide, phenyl mercuric acetate, in a special water-soluble jelly base. 'Mersagel' acts directly and rapidly upon infecting fungi yet is harmless and non-irritant to the normal skin; it is also

effective in protecting those in contact with infected persons and preventing recurrence of the disease after infection. 'Mersagel' is colourless, odourless and clean to use and is conveniently applied directly from the tube or jar.

## OPEN SEASON for fungus skin infections

1½ oz tubes • 16 oz jars

GLAXO LABORATORIES LTD. GREENFORD, MIDDLESEX. BYRON 3434

## THELESTROL HEXESTROL + PHENOBARBITAL

Compressed tablets each containing 3 mgs. of Hexestrol (Dihydrodiethyl Stilbestrol) and 20 mgs. of Phenobarbital

Tablets are scored to facilitate dosage reduction

Indicated in the treatment of menopausal syndrome including nervous manifestations

Bottles of 20, 50 and 100 tablets

Professional samples available to members of the Medical Profession

## *Vitamin Therapy—its uses and limitations*

### **BETTER NEWS ABOUT BEMAX**

Increased supplies of Bemax now being sent to Chemists should ensure that prescriptions will again be met in full. There will also be more Bemax for the priority classes, *i.e.*, expectant and nursing mothers, children and the aged, with perhaps a little left over for the ordinary consumer.

Further, the new Bemax tablets are now available and have been warmly welcomed. Containing 50 per cent. Bemax, they are a vitamin B supplement with uses similar to Bemax itself and the recommended dose provides 200 i.u. B<sub>1</sub>—approximately the same as the daily dose of Bemax. The tablets are very palatable and are intended to be chewed.

Doctors are invited to write for a complimentary carton so that they may test the tablets for themselves.

### **BEMAX Stabilised cereal embryo**

1 oz. of Bemax provides approximately :—

Vitamin B <sub>1</sub> -	- 0.45 mg.	Vitamin E -	- 8.0 mg.	Available	
Vitamin B <sub>2</sub>		Manganese -	- 4.0 mg.	Carbohydrate	39%
(Riboflavin) -	0.3 mg	Iron -	- 2.7 mg.	Fibre -	- 2%
Nicotinic Acid -	1.7 mg	Copper -	- 0.45 mg.	Calorific Value -	- 104
Vitamin B <sub>6</sub> -	- 0.45 mg.	Protein -	- 30%		

*Vitamins Limited*

Upper Mall, London, W.6

For Personal Use

## **VAPEX** INHALANT

Now re-introduced exactly as before in quality and price. The pleasant, unobtrusive aroma of Vapex, its efficacy in the relief of the common cold and as a prophylactic, make it particularly suitable for personal use by the medical profession. A drop on the handkerchief lasts all day.

### The Measurement of Human Skill

SIR.—Prof. F. C. Bartlett's Oliver-Sharpey lectures on "The Measurement of Human Skill" published in the *Journal* of June 14 (p. 835) and June 21 (p. 877) prompt me to put down a few observations on clinical diagnosis which I believe to have a sound scientific basis. As is stated, investigation proceeds step by step, the fitting of one set of responses to another, until the diagnosis is completed. Here the conscious mind cal's on the stored knowledge of the deeper subconscious levels, and between them the mystery is solved.

Now, in protective muscular reactions such as the sudden application of a car's foot-brake, closure of the eyelids, or the placing of a hand in front of the face the conscious mind has not functioned except to receive the receptor impulses. The very complicated mechanism involved in the effector response has performed its work subconsciously. Similarly in mental reactions, immediately after the receipt through eyes, ears, or fingers by the brain of a skilled clinician, the correct diagnosis may thrust itself into consciousness: the step-by-step route has been short-circuited. Before seeing the patient he is heard to cough, and in a flash "pneumonia," "basal congestion," or "tracheitis" obtrudes itself. The hand placed indiscriminately on the abdomen before inspection or the history questioned—an unorthodox but very valuable procedure—may give rise to "appendix" or "acute abdomen." And in general practice these conditions are very rare in comparison with the number of abdomens examined, and reference here is only to obscure cases, not to those where a reasonable prediction can be made before examination. A fleeting glance at a head above the bed-clothes brings out "perforated gastric," and innumerable times a glance brings forth a sense of immediate urgency, when a subsequent more careful inspection reveals nothing startling.

It must be emphasized that these are not snap diagnoses, nor is any attempt being made to produce quick results, the performance of which is much slower and due to a completely different mechanism. Further, such practices produce a far greater percentage of error than the events described, which are almost invariably correct. These immediate effector responses occur comparatively infrequently and very erratically, but are so uniform in their characteristics as to leave no doubt as to their definite entity as a class. Their appearances bear out the statement that often the participation of the conscious mind slows down the reaction time. It is an essential that the mind be almost or entirely dissociated from the patient, in fact "wool-gathering," for the diagnosis to be presented with such precipitance.

How to measure this skill must be left to others. Its use in a busy general practice is to focus attention on a patient who needs the most thorough investigation by oneself and, if the results are not conclusive, by the appropriate consultant.—I am, etc.,

Hove, Sussex.

FRANK PORTAS.

### Citrate in Urinary Infection

SIR.—Recent discussion on the use of citric acid drinks with sulphonamide therapy reminds me of the use of citrate in another sphere, whose full implication is not, I think, generally realized. Diabetics not infrequently suffer from a urinary tract infection and receive in consequence large doses of alkaline citrate. Now citrate is fully absorbed and fully utilized ("oxidized") in the body in a similar manner to carbohydrate. The method by which this occurs is, briefly, believed to be as follows: citric acid is converted to aconitic acid, which enters the "tricarboxylic acid cycle," and is converted through several stages to oxalo-acetic acid, losing two carbon atoms as carbon dioxide and releasing energy. Oxalo-acetic acid may be further decarboxylated to pyruvic acid, which may actually

be converted into glycogen, or which may condense with oxalo-acetate, losing another carbon atom by decarboxylation in the process and re-forming aconitic acid, thus completing the cycle.

Now whether citrate is pictured as being converted into carbohydrate via pyruvate or as being fully oxidized in the tricarboxylic cycle is immaterial—the point being that all six carbon atoms in the citrate molecule are readily available for full utilization for the production of energy by complete oxidation, so replacing and "sparing" an approximately calculable amount of carbohydrate.

Now the two full oxidation equations for glucose and for citric acid are:

so that, taking the amount of oxygen consumed to be equivalent to the energy liberated, we have:

1 gramme-mol. citric acid  $\equiv$  3/4 gramme-mol. glucose.

$\therefore$  213 g. sodium citrate  $\equiv$  3/4  $\times$  180 g. glucose, or

1 g. sodium citrate  $\equiv$  0.6 g. glucose (approx.).

Assuming our patient to be getting the rather large dose of 60 gr. (4 g.) 4-hourly (which may well be needed for urinary alkalization), this means that he is having the equivalent of some 12 g. of extra sugar per day. Admittedly this is not very much when spread out over the day, but it should theoretically be taken into account in adjusting the dietary requirements of the diabetic.

This idea of the availability of citrate has other points of interest (at least in theory), such as the additional energy it presumably supplies to the ill febrile patient with anorexia who is being treated, for example, with sulphonamide, accompanied by the routine citrate; its theoretical action in checking a hypoglycaemic attack; the likelihood (on present theory) of its utilization in severe diabetics without insulin, in whom sugar is of no value.

I am very grateful to Dr. E. Baldwin, of Cambridge, for his help in regard to the biochemistry in this letter.—I am, etc.,

Wolverhampton.

W. P. U. JACKSON.

### Pethidine in Labour

SIR.—I have read with interest Dr. J. H. P. Giff's letter (June 21, p. 901) stating that his experience shows the action of pethidine in labour to be unreliable. Dr. Giff does not state at what stage of labour he commences to use this drug, or any information regarding dosage, while I find that the time at which it is used is a most important factor in obtaining a successful result.

My experience with the drug, based on a very considerable and extensive usage over the past two and a half years, is the exact opposite to that of Dr. Giff: I have found the drug most reliable. The effects of pethidine in labour are helped by the previous administration early in labour (where the os is 1-2 fingers) of "seconal" 3 gr. (0.2 g.), though I have found that about 15% of patients vomit this unchanged, and I find, on short acquaintance, that "tuinal" is better.

Pethidine itself is administered hypodermically in doses of 100 mg. when the os is about 1/3 to 1/2 dilated, this dosage being repeated

if necessary hourly for three doses. If 300 mg. has no effect, I find it useless to administer more.

The administration at this stage does slow down labour for about 30-40 minutes, giving the mother rest and some sleep, after which the pains get stronger and labour is shortened, the mother being completely relaxed, and possibly asleep, between pains, but able to understand and co-operate during pains. It is worthy of note at this point that pethidine used in cases of "rigid cervix" exerts an effect which can only be described as dramatic. I have found that pethidine may safely be administered up to an hour before delivery with no adverse effects on mother or child, and after its birth, provided the cord is not cut *until pulsation has ceased completely*, there is no interference with the child's respiration and no cause for anxiety. If, however, it is necessary for the mother to have a general anaesthetic within this period, the induction of anaesthesia is prolonged owing to the maternal respiration being shallower than normal.

The administration of pethidine as outlined above eliminates in most patients the necessity for the Minnitt gas-and-air apparatus, which I find, even with a properly fitting individual facepiece, a most unsatisfactory and unsatisfying form of analgesia in about 55-60% of patients. In my experience pethidine used as above with premedication is eminently satisfactory in about 95% of patients and useless in the remaining 5%. There are occasionally nausea and even vomiting during administration late in the first stage, though this may be due to the onset of the second stage. There are no effects after parturition on either mother or child, and the maternal comments are most favourable and gratifying.—I am, etc.,

London, S.W.14.

A. B. WATERS.

### Physical Therapy of Mental Disorder

SIR,—The recent correspondence on physical therapy in mental hospitals (June 14, pp. 861-2) has prompted me to draw to the attention of the profession a matter which, although serious and sinister in its implications, does not appear to be generally known among medical men who are unfamiliar with present-day mental hospital conditions. I refer to the increasingly common practice of inflicting on unwilling certified patients certain unnecessary and mutilating surgical procedures, particularly indiscriminate leucotomy and tooth-pulling, in a manner which is unpleasantly reminiscent of the practices of the Nazi concentration camps. The type of case in particular which I have in mind is the chronic psychotic patient under certificate in whom volition and ability to give or withhold consent are unimpaired by the disease present. In the course of several years' mental hospital experience I have seen a number of such unfortunates subjected against their will to procedures of the kind just described.

Such a practice, in my opinion, constitutes an inexcusable violation of fundamental human rights. It was pronounced to be a crime against humanity by the Nuremberg tribunal, a court composed of judges of the highest legal standing, and at the subsequent trials a number of German doctors convicted of such practices received the death sentence. The fact that the patient happens to be certified, and a form of consent is obtained from a "responsible relative," cannot, in my opinion, justify the forcible infliction of such operations on any human being: since, in my experience, the relatives of patients of the mental hospital class are as often as not even more lacking in insight and intelligence than the patient himself. In this connexion it is worthy of note that, in this as in all civilized democratic countries, even the convicted criminal is protected by law from such violation of his person.

Let it not be supposed for a moment that I am opposed to the use of physical therapy in mental disorders. My views on this subject were made clear in a previous letter in this *Journal* (May 31, p. 778). What I am opposed to is the abuses of such treatment just described, which in my opinion constitute an attack not on the problems of mental disorder but on the rights and liberties of the individual, and have contributed more than anything to bringing discredit on a new and promising form of therapy. I do not doubt for a moment that such practices are motivated by misguided therapeutic zeal rather than by wilful cruelty. Nevertheless, their sinister implication remains, and one can only conclude that they are only one more aspect of the insidious attack which is being made to-day from certain

quarters on individual rights and liberties. The German war-crime trials received sufficient publicity at the time to make a profound and shocking impression on the public conscience; yet their lesson and implications seem to have been only too speedily forgotten. Let us therefore take warning before it is too late. *Facilis descensus Averno*.—I am, etc.,

London, S.E.6.

G. TAYLEUR STOCKINGS.

SIR,—It appears that the important issue which your correspondence reflects is whether psychiatrists are going to take psychology seriously or whether they are instead going to side-step the body of analytical knowledge which has been accumulated. By confusing quick, dramatic (psychologically magical effects with real results, they go some way at least towards disregarding the developments of the last fifty years or so. Besides this question the rest of the discussion is relatively unimportant for if psychiatry really substituted magic for knowledge the long-term results would be disastrous to the cause of humanity.

At the present time, when most psychiatrists contrast physical therapy with psychotherapy, they are comparing a method which is familiar to them with one of which they can speak only as more or less talented amateurs. By this I mean that on the whole psychiatrists are untrained and unqualified psychotherapists (I hasten to add that there are a growing number of exceptions). It is not, however, their fault that they are untrained, since training is available only in certain regions of the country. But this should not blind us to the realities, which are very well illustrated by the assessment of results from physical methods of treatment. These are always couched in psychological terms which, to the analyst, are naive and unconvincing in the extreme. If psychiatrists unqualified in psychotherapy would openly state their lack of training and even tacitly admit it, then we should know that they are giving an untrained opinion, and we should be more tolerant of the inability to differentiate knowledge from speculation. As matters stand, there are almost bound to grow up two hostile camps in psychiatry.

As one who has seen nothing but a few bad results from physical methods of treatment, I regard myself as unqualified to make any statement about them which is not prejudiced. I will dare to say that I know more about medical and surgical methods than most psychiatrists know about psychotherapy, so that I am likely to treat these methods with the respect due to them. I invite psychiatrists to exercise a similar caution when discussing a subject they do not understand. Their lack of caution only induces feelings of disrespect and even contempt towards them, not only among our own profession but also among the better informed lay public, many of whom are able to understand the significance and value of psychotherapy in a realistic and objective way.—I am, etc.,

London, N.W.1.

MICHAEL FÖRDIAM.

SIR,—The letters on this subject in your columns are interesting and remarkable in displaying the prevalence of a lack of charity for the other fellow's point of view and so of an inability to understand and appreciate it. It is not surprising that the correspondence degenerates at times into an attack on mental hospitals, so that their liquidation is demanded by Dr. T. Gladstone (June 28, p. 942). Dr. Clifford Allen (p. 942) throws much light on the controversy by pointing out that practising psychiatrists for the most part see either psychotic or psychoneurotics according to the method of treatment they have become familiar with and, let us assume also, proficient in. Patients who have failed to respond to one line of treatment do tend to pass into the hands of practitioners of the other cult. There is thus a tendency for each other's failures to be seen, and a false conclusion may be readily drawn as a result.

A few of us have been fortunate enough to escape these unfortunate limitations in experience, and as medical director of an out-patient psychiatric and child guidance service and as medical superintendent of a mental hospital I am responsible for providing for the needs of both groups of patients. I am associated with practitioners familiar with both lines of therapy and am in daily contact with patients undergoing both forms of treatment. Owing to the war our in-patient mental hospital side is still very greatly reduced in numbers, and although we have seriously considered leucotomy in some cases in no instance has

this been done. In this position I am convinced—at this stage I feel only personal testimony from those whose experience seems to justify its value can make a useful further contribution to this correspondence—that E.C.T. and insulin treatment have a definite sphere of usefulness as therapy at the present time and with our present knowledge.

One valuable point at least arises from the critics: effective steps must be taken to ensure that the distressing manifestations of the treatment—the sight of patients convulsed or unconscious, the cry on induction, etc.—shall not be seen or heard by any other patients in the treatment unit. May I assure Dr. Allen that many of “those who use shock treatment” fully appreciate this need. From what he says it seems some still need convincing, but this is no argument against its employment with adequate precautions.—I am, etc.,

St. Albans.

W. J. T. KIMBER.

### Calories and the Olympic Games

SIR.—Much, perhaps too much, has been spoken and written about our diet, and the general conclusion is that even for the ordinary person the average calorie intake is a good deal too low. Scientists, however, have had little to say regarding the necessary training diet for our athletes competing in international sport and who, next year, will be expected to uphold Britain in the Olympic Games. Yet it is clearly as unfair to expect them to compete successfully without proper feeding as it would have been to expect our Army to fight on an empty stomach.

Admittedly measurable energy used in sports is not as much as one would imagine, and an additional 500 to 700 calories would probably cover the most strenuous games (Deutsch and Kauf). But anyone who has run himself out in a mile race or played five sets of international lawn tennis or an hour's intensive squash will admit that it cannot be done without long and regular training, if the body is to be fit to fight again next day or even next week. Regular training means an intake of protein of not less than 100 g. a day—the equivalent of a good steak—while Elmer Berry says that the optimum diet for an athlete includes 5 pints (2.8 l.) of milk, 8 eggs, and an ounce (28 g.) of butter a day; not to mention the oft forgotten 30 g. of salt which would stop both the cramp and a good deal of the lassitude of which our representatives at sport have recently complained.

Most foreign competitors in our sporting events are wise enough to bring their own fats and protein with them. The Australian lawn tennis team tell me they have 500 lb. (225 kg.); and of course they have had whatever they wanted to eat for many months. Whether the Government should give special rations to Olympic and other representative athletes is, I suppose, a matter for debate; but the stomach cannot suddenly deal with increased food, and a long-term policy is the only one which would have any beneficial results. We fed our representatives specially in war: why not, one can argue, in peace? Certainly if we do not it must be a foregone conclusion that, however we may compare in technical skill with the rest of the world, we shall be unable to compete as regards stamina. That is a scientific fact that not only the public but many doctors, too, appear to miss.—I am, etc.,

London, W.1.

NEVIL LEYTON.

### Penicillin for Osteomyelitis

SIR.—The development of an argument on the value of penicillin in the treatment of acute osteomyelitis is rather refreshing. The fact that time and energy are available for people to question the unquestionable implies a quiescence of the turmoil of war and a rest from the alarms of State service.

No experienced person in his or her senses could really question the value of penicillin in this condition. It has completely transformed the picture of acute osteomyelitis. Consequently I do not wish to detract in the slightest from the contribution by Mr. T. Twistington Higgins, Mr. Denis Browne, Dr. M. Bodian (May 31, p. 757), and it is unnecessary to elaborate their reply (June 28, p. 947) to Drs. J. Trueta and M. Agerholm (June 21, p. 899), which infers that nobody need take much notice of what the latter say. But I think it is reasonable to mention the importance of protecting long bones against stress. This precaution is most necessary about the end of the fourth

week, long after the temperature has subsided and healing of any wound or abscess has occurred. From that time to about the end of the seventh week decalcification necessarily resulting from the initial infection and necrosis reaches its peak, and reparative processes have not developed sufficiently to strengthen the weak part of the bone. I will not take up your space with details, but I have a vivid recollection of a child in the early days of penicillin who fractured her femur because her recovery was so spectacular that we failed to appreciate the importance of the zone of spotty decalcification.—I am, etc.,

Liverpool.

BRYAN MCFARLAND.

SIR.—We should like to change this correspondence from an argument to a constructive discussion of the best way of discovering how to obtain the fullest benefit from penicillin in acute osteomyelitis. It is clear that a number of centres working on the treatment of acute osteomyelitis with penicillin have come to different conclusions on the best method of treatment, and the variations are probably due to the relatively small number of cases which any group has treated. We suggest that the time has come for a committee to be formed to review the results so far obtained in the treatment of this disease, and to draw from the experiences of the several centres some general conclusions which could serve as a guidance for the future.

Such a committee might determine: (1) The best penicillin treatment in relation to the age of the patient, the infecting organism and its resistance to penicillin, the site of the lesion, the delay between onset of infection and the beginning of penicillin treatment, (2) The importance of the removal of pus and the best way of carrying this out, (3) The value of immobilization and the best means of deciding when it can be safely discontinued. In addition, a scheme for classifying the cases and a standardized method for recording results might be established so that different series could be readily compared.—We are, etc.,

J. TRUETA.

M. AGERHOLM.

Oxford.

### Leprosy and its Problems

SIR.—Referring to the leading article on “Leprosy and its Problems” (June 7, p. 813), I note two rather serious mistakes in the last two paragraphs.

1. “Nodular leprosy may possibly prove intractable.” This is entirely the opposite of the trend of my article on sulphone treatment of leprosy on p. 798. There, under “Suitable Type of Case” is written: “It is the lepromatous or severe type of leprosy to which the sulphone treatment has been applied.” The lepromatous type is the modern nomenclature for nodular leprosy, and it is this type for which the sulphones are proving so very useful.

2. The number of lepers in the world is mentioned as two million, of whom 97.5% are Indian or African. This is quite contrary to the statistics which have been generally approved. In *Leprosy* (Rogers and Muir) a table is given on pp. 13–15 which calculates 3,291,000. It is said that this is probably an underestimate, and five million is as near as we can at present get to the true figure. Of the 3,291,000, one million are given as being in China, which would, I think, be quite contrary to 97.5% in India and Africa.—I am, etc.,

London, S.W.1.

E. MUIR.

### State Medical Service in New Zealand

SIR.—It is good to read in your columns (June 14, p. 865) Sir Ernest Graham-Little's substantiation of the veracity of Mr. Porritt's injunctions against the State form of medical service in New Zealand. I have repeatedly denounced the present Health Act as the progeny of an unholy marriage of the Ministry of Health and a Party medical clique. I have pointed this out as fatal to any success both in meetings of the B.M.A. and the R.C.S. The only sure foundation for a completely comprehensive and satisfying health service rests on data only to be derived from the technicians of medical practice, whose life-long job is the conversion of disease to health. The problem is abstruse and intricate. Knowledge is doubly vital for an objective of such solemn import as the health of a nation. We alone are the informed section of the community and hold the key to successful planning. Every bit of medical wisdom needs

representing, and it is incumbent upon the authorities to seek evidence from all the best brains of the profession.

There should be set up at the instigation of the Ministry of Health a new medical planning commission, whose members are chosen regardless of political views but acknowledged by their colleagues as fit spokesmen by reason of their professional knowledge, vision, and humanitarian spirit. This commission would deliberate while the present Act, shed of its controversial features, is implemented as an interim measure, and while the country is getting on its feet again.

All of us should follow Sir Ernest's line, repeat this truth, and at least free our consciences of apparent acquiescence in the degradation of a great and noble profession and its work.—I am, etc.,

Bristol.

A. WILFRID ADAMS.

SIR,—The profession owe a great debt to Sir Ernest Graham-Little for the amount of work he has undertaken regarding the national medical service.

Sir William Fletcher Shaw (May 31, p. 782) does not agree with the conclusions of Mr. Porritt and suggests that conditions in N.Z. are satisfactory to the doctors but does not give the reason. The fact is that the general practitioner receives 7s. 6d. per visit or consultation, paid by the Government, and such additional fee as he likes to charge the patient, plus mileage for visit. The doctor in N.Z. is satisfied because he is receiving not a capitation fee but a flow of income as long as he is willing to sit in his consulting room and collect the signed claim forms.

There are few queues in N.Z. except for cigarettes and the doctors. The reason there is difficulty in obtaining the services of the doctor at night and week-ends is that he is worn out with excessive work; and again nobody in N.Z. works at night or week-ends. The forty-hour week has demoralized the whole community. You are lucky to get a plumber in a fortnight. These are the views of resident doctors in N.Z.

It is suggested by Sir William Fletcher Shaw that an increase in the number of doctors will solve the problem basically due to free treatment. Does he think the doctor will be on tap for 168 hours while the rest of the community are not allowed to work more than forty hours a week by law and any earnings at night or week-end are taken over in taxation. If the doctors in this country or N.Z. ever agree to a capitation fee they will end with a State medical service.—I am, etc.,

Beckenham, Kent.

A. E. BLACKBURN.

### General Knowledge and General Practice

SIR,—Dr. D. N. Baron's hobby-horse is a common one; the clacketing of its hoofs rings in our ears from student days—not that we haven't bestraddled the beast ourselves, but we have learned not to ride side-saddle. Of Dr. Baron's basic premise (June 21, p. 902)—to wit, that the standard of culture among medical students (and doctors) is distressingly low—there can be no criticism. Of Dr. Baron's recommendations for improvement we say unblushingly they are not Good-enough. Culture is an attitude of mind. The cultured man is one who, as the result of many influences on his mental development, has learnt an instinctive habit of distinguishing the good, the true, and the beautiful from the bad, the false, and the ugly.

Has Dr. Baron asked himself why, with so little interest displayed by the university authorities, a number of students (including, we presume, Dr. Baron) managed to achieve such an outlook on life as he himself deems desirable? By the time the age of medical studentship is reached the seed is already sown. The opportunities for intellectual advancement are available for those who have the interest to seek them out, and if the demand were greater the university concerned would be forced to provide greater facilities. At the moment these are inadequate only in the sense that one feels a larger number of students should be making use of them.

Let Dr. Baron realize that the foundations of a cultured mind are laid much earlier than the time of the anatomy course. Let him recognize that the ability to discourse on existentialism is no more the mark of a cultured intellect than the accurate knowledge of the course and relations of the greater superficial petrosal nerve is the *sine qua non* of a general practitioner. His

plea should be for better schools and broader education; brighter architecture and more opportunities for the mass of people to spend their leisure time in more beautiful buildings, pursuing more intellectual hobbies than are normally found in the picture- or public-house.

We medicos are not a race apart. We are admittedly an uncouth lot, but like Garson Kanin's millionaire junkman<sup>1</sup> we are "more couth" than the next man—on the average. "The great happiness of life is to be neither better nor worse than the general run of those you meet with." Dr. Baron wisely seeks to raise us all to his own high level, but does he consort only with doctors? And then to seek success by compulsion he will have us all crying with Falstaff:

"Zounds, an I were at the strappado or all the racks in the world, I would not on compulsion."

London, S.W.16.

DAVID L. KERR.

## POINTS FROM LETTERS

### Physical Therapy of Mental Disorder

Dr. D. W. ABSÉ (Abergavenny) writes: Although the spirit which Dr. Winnicott (May 17, p. 688) proceeds to deal with subject is scientific, his argument is marred by the polemical of analysis. After all, in psychotherapy the unconscious phantasia of the patient are engaged and the therapist assumes the mag mantle of Elijah no less than in physical treatment. Modern commerce is derived from systems of barter, and these replaced the Such is the unfolding of civilization. The modern physician resulted from the magician's progress, as far as this has reached. my mind the important aspect of the matter is that the physic should be conscious of the role he is assuming *vis-à-vis* the pati so that he may be able to heal more effectively. Nowhere is more important than in shock therapy, and it is one reason (am others equally important) why the conception of "psycholog shock" needs to be developed. It is to be remembered that it are those who regard the psychological factors which emerge du convolution therapy as responsible for the changes wrought in patient. This is only to say that these "factors" can be appr ated on a psychological plané. It is unlikely that they can appreciated in terms of physiology any more than the onset development of the mental disorders to which shock methods habitually applied. . . . Shock methods of treatment are unplea for the patient, as anyone capable of making adequate psycholog contact with the patient has to allow. They can sometimes d the patient deeper into his psychosis, just as they can somet cause a remarkable emergence and reality-adjustment. It is a fur complication that faulty judgments in regard to a patient's respo to treatment easily arise. . . .

### Choice of Specialist

Dr. G. C. PETHER (Colechester) writes: Dr. Eustace Ship (June 14, p. 866) has touched on a matter which can elaborated and is of fundamental importance. I think it be admitted that the doctor-patient relationship as it now is able to give the patient, whose interests are paramo a fair deal. This is at least true in private practice. I patient or his relatives wish for another opinion they can it. . . . Some years ago, when in a subordinate capacity a hospital, my opinion was overridden because the su intentend considered that a specialist, who only saw the patien intervals, could judge better than I. As a result of this unnecessary operation was performed and the patient died. I not suggest that in the Services this occurred more or less c than in civil life; yet in theory the colonel knew more than major and the major more than the captain. . . . Where will patient stand in a National Health Service? The doctor in area will presumably be there as a result of "negative directi The specialists from whom other opinions can be obtained, as other G.P.s, will also be there by some similar process. Will patient be able to choose a second opinion? . . .

### Pruritus Ani as an Allergic Condition

Dr. E. M. FRAENKEL (London, W.) writes: I can con Dr. G. L. Davies's remarks (June 28, p. 950) to be correct in s cases of anal irritation in allergic patients, in whom it started v they used medicated toilet paper and stopped after discontinuin do so. In my case of pruritus ani (June 7, p. 823), however, toilet paper cannot be blamed, as the patient had used cotton-wool only for a long time due to the intensely painful irritation.

## Obituary

### WILLIAM GOUGH, F.R.C.S., F.R.C.O.G.

William Gough, formerly professor of gynaecology at Leeds University, died on June 29 at the age of 71. He was born in Leeds in 1876, and received his professional training in the Leeds school of medicine, where he was awarded the William Hey medal as the most distinguished student of his year. He took the London B.Sc. in 1895 and the M.B., B.S. in 1900. At the intermediate M.B. examination he won the gold medal in physiology and histology. In 1909 he became F.R.C.S., and on the establishment of the College of Obstetricians and Gynaecologists he was elected a foundation fellow.

After qualifying, he was Mayo Robson's house-surgeon, and acted for a period as private assistant to Lord Moynihan. He had to wait some time before an honorary hospital appointment became available, and in the meantime he engaged in general practice and also directed a laboratory of clinical pathology. He used to produce excellent histological preparations with the most primitive equipment and in an incredibly short time. He always maintained that these preliminary activities formed a most valuable foundation for his later special work. In 1909 William Gough was appointed to the staffs of the Leeds Maternity Hospital and the Leeds Hospital for Women. He became a lecturer in the University of Leeds and held the chair of gynaecology from 1929 to 1936. He gave much unassuming and painstaking service to the Royal College of Obstetricians and Gynaecologists as a member of the council and as vice-president. He was a loyal and enthusiastic member of the North of England Obstetrical and Gynaecological Society, and of the Gynaecological Visiting Society. He spoke little, and wrote less, so he was little known outside the circle of his immediate colleagues and pupils. Here, however, his influence was deeply felt, and it was invariably characterized by decency and generosity.

He readily gained the trust and confidence of his patients, for they at once recognized, and rightly so, that in his hands they would receive the best possible treatment. As an operator he was ambidextrous, using the scalpel with either hand but the left for preference. There was nothing spectacular about his methods. He did not give the impression of being a "brilliant" operator, but every operation he performed seemed to be done simply and swiftly. This speed was not gained by the sacrifice of any essential detail of technique.

His many activities in hospital work, teaching, and an extensive private practice were sufficient at times to strain even his exceptional capacity for work, but he was never flurried, never worried, and never lost his temper. His family life was singularly happy. The tragic death of his elder son, a young man of great promise, must have been a terrible blow to him, but it was borne with wonderful fortitude. He is survived by a widow, one son, and four daughters.—A.G.

### CHARLES PHILIP BRENTNALL, M.C., M.B., F.R.C.O.G.

Charles Philip Brentnall died in Manchester on June 26 at the age of 56. Son of the Rev. Edward Brentnall, he received his early education at St. Paul's School, London, and the Manchester Grammar School, and then, having gained the Dreschfeld Scholarship, proceeded to Manchester University to study medicine. When he was in his second year his father moved to a living in West Lancashire, so Brentnall transferred to Liverpool University. There he had an unusually brilliant career, gaining distinction in the M.B. examinations in anatomy, pharmacology, and pathology, and also winning the Gee Prize.

He qualified in 1915 and, after holding the post of house-surgeon to the Liverpool Northern Hospital, joined the R.A.M.C. He served in the field in Gallipoli, Palestine, and France, rose to the rank of major, and was awarded the Military Cross. After the war he returned for a time to work in Liverpool and was then appointed as a resident to the hospital which he served for the rest of his life—St. Mary's, Manchester. At St. Mary's, he was successively house-surgeon, resident obstetric officer, resident surgical officer, and registrar, and he was elected to the honorary staff in 1923.

Brentnall's work as a gynaecologist was typical of the man. His approach to any problem was a quiet one, and his methods were gentle. In consequence his surgical results were outstandingly good, and his technique served as a model for his juniors. As was only to be expected, he built up a large consulting practice, and his services were in demand over a wide area. His appointments outside Manchester included those of honorary obstetrician to the Stretford Memorial Hospital and honorary consulting gynaecologist to Warrington Infirmary. A foundation member of the College of Obstetricians and Gynaecologists, he served on the council for six years, being raised to the fellowship in 1938. He was also a member of the Gynaecological Club.

Brentnall's contributions to gynaecological literature were made largely in the form of communications to the North of England Obstetrical Society, of which he was a fellow. At its meetings he could always be counted upon to add something of interest to a debate or to give a word of encouragement to a junior member. It was indeed tragic that shortly after his election as president he should be stricken by the illness from which he eventually died.

In his private life Brentnall was singularly fortunate, and he was never so happy as when, in his own home, he could enjoy the companionship of his family and friends. He leaves a widow, a daughter, and a son who is studying medicine.

## Medico-Legal

### DESCRIPTION OF A CHEMIST

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A recent case concerning a chemist turned on the description of premises where no qualified chemist is in charge. Under the Pharmacy and Poisons Act, 1933, it is unlawful for a person to use a description in connexion with the business reasonably calculated to suggest that he or anyone employed in the business possesses any qualification with respect to the selling, dispensing, or compounding of drugs or poisons other than the qualification which he in fact possesses. A registered qualified chemist and druggist named Mr. Spink owned eleven chemists' shops. Qualified assistants were in control at ten of these, but none was available for the eleventh. This shop, like the others, was carried on under the name of "Spink's, the Chemist," but it had a placard in the window stating that owing to war circumstances there was no qualified assistant in charge of the shop and medicines could not be dispensed. An inspector of the Pharmaceutical Society bought glycerin and rose-water in a bottle labelled "Spink's, Chemist," and the society prosecuted Mr. Spink for a breach of the Act. The justices dismissed the case, and the Society appealed.<sup>1</sup>

The High Court upheld the justices. Lord Goddard. Chief Justice, refused to read the Act as though it said, not "he or anyone employed in the business" but "he or any person in control of premises where the business is carried on." He also pointed out that, whereas the Act says that the word "pharmacy" in a description is to be deemed to be reasonably calculated to suggest that the owner of the business and the person in control are registered pharmacists, yet there is no such prohibition of the use of the word "chemist." His Lordship thought that the title complained of meant only "This is a shop belonging to Mr. Spink, who is a chemist." The word "chemist" over the shop, taken together with the placard, was not reasonably calculated to suggest that the person in charge had a qualification which in fact he had not. Mr. Justice Atkinson and Mr. Justice Oliver agreed.

<sup>1</sup> *Dentley v. Spink* (1947) 1 All E.R. 835.

The Minister of Labour and National Service has formulated new Regulations (H.M.S.O., price 6d.) in the light of the report of the Dust-Tile Committee, published in 1943, and of recommendations made by the National Council of the Pottery Industry in 1945. Conferences for examining the Regulations will probably be held in the autumn.

# Medical Notes in Parliament

## FOOD AND HEALTH

On July 1, on the estimates for the Ministry of Food, Mr. J. S. C. REID opened the debate with a reference to the statement of the previous day by Mr. Dalton indicating coming reductions in imports. Mr. Reid said he had yet to see any survey which showed that the majority of the people of this country who did not have access to canteens and restaurants consumed more than 2,400 calories a day. Calories told only half the story. Otherwise bread and water would be a good diet. Weight for weight there were more calories in bread than in stewed steak and twice as many calories in sausages as there were in chicken. Weight for weight stout had more calories than smoked herring.

Mr. STRACHEY said the average number of calories consumed per head per day at the moment by the people of this country was between 2,880 and 2,890. The figure of 2,325 which had been adduced by Col. Walter Elliot was what the national figure would be if no one in the country consumed any food in catering establishments and if some types of rationed foods under the personal points scheme were disregarded. Using this completely false figure Col. Elliot alleged that the nation was gravely undernourished, and his less cautious supporters alleged that it was starving to death. The figure of 2,325 came from the National Food Survey for the first quarter of 1947. The comparable figure in 1941 was 2,360, in 1942 it was 2,253, and in 1943 it was 2,315. If the nation was slowly starving to-day it was starving a little more quickly while Lord Woolton was in office. He did not suggest that 2,890 was a highly satisfactory level, but it was a good level in comparison with previous periods. The Government aimed to put the whole population of the country upon a higher level. To-day the difference of intake among individuals was largely according to need instead of according to class. There was comparatively little difference in the intake of the different wage groups.

Mr. BAKER WHITE pointed out that 84% of the meals eaten in this country were eaten in the homes and only 13% in catering establishments. National supplies of fruits including tomatoes and pulses were more than 20% below pre-war levels, but supplies of vegetables were about 10% above pre-war, and potato supplies had increased to about 64% above the pre-war level.

Mr. MICHAEL FOOT said tests by experts in this and other countries proved that the infantile mortality rate and the maternal mortality rate gave a proper indication of nutritional standards. In England during 1936 the infantile mortality rate was 62 per thousand. To-day, under Mr. Strachey, was 46 per thousand and still going down. The same was of the maternal mortality rate, which was the lowest on

By comparison with pre-war days the height and gth of children in this country were greater. In Plymouth ldren born and brought up in the "blitz" were healthier, ronger, and better than any children ever born in this country before.

Mr. WILFRID ROBERTS said he had obtained the article by Dr. Bicknell entitled "Dying England." It was first-class political propaganda with opinions on statistics, political economy, and agriculture, on the last of which Dr. Bicknell quoted what seemed to him, Mr. Roberts, to be quacks.

Mrs. AYRTON-GOULD said Dr. Bicknell knew nothing about the unemployed and nothing about food. Before the war half the population of Britain spent from 4s. to 8s. a week on food and 50% of the population had an average of 2½ oz. of butter a week, whereas the nation was now getting 3 oz. per week per head and everyone was able to buy it. The same 50% had 3 oz. of margarine a week, which was the same as the present ration. The 1s. 2d. worth of meat which the nation now bought weekly was far above the amount the average person could afford to buy before the war. The consumption of milk to-day was 50% more than before the war. The excess went in the welfare services and to the people who needed it most. All ordinary housewives were able to buy 2½ pints a week, which, according to Sir John Orr, was the average milk consumption before the war. That was why the health of the population was much improved. Deaths from tuberculosis in England and Wales in 1935 numbered 29,201. The population had increased in the subsequent ten years, but the figure for 1945 was 23,955. People who talked about the nation being ill-fed talked absolute nonsense. The nation was being well fed, though monotonously fed.

### More Milk

Lady GRANT said the nation was consuming 30% more milk at the expense of butter and cheese and processed milk. She

quoted figures from a review in 1937 by Sir William Crawford. They concerned the group with incomes below 48s. per week. In 1937 these people consumed on an average 26.8 oz. of meat per week while the nation now consumed 16.2 oz. per head. They then consumed 3.6 oz. of bacon whereas the ration was now 2 oz. In fats they consumed in 1937 10.2 oz., while the ration was now 7 oz. Since 1945 there had been cuts in several vital rations while more goods had been based on points. The nation was consuming more starchy products, and who would say these products were a good substitute for fats or proteins? The result of the lack of quality in the diet was having a great effect on the people's will to work and brought chronic fatigue with many minor ailments which were not notifiable, such as general debility, and gastritis.

Dr. HADEN GUEST asked how the Government was going to fortify the health of the people and give them extra resistance in the event of the next winter being as bad as the last. The difficulties at present were not due to food, which was extremely good, but to the fact that all were suffering from the results of war strain. He thought there should be an extension of food for certain classes of heavy workers, including miners. Much could be done by ensuring that all the children entitled to priority milk actually received it. He believed that they did so in the towns. He hoped that the priority supply of eggs to children up to the age of 2 years could be extended to the age of 5, 6, or 7. Extra proteins for heavy workers, particularly miners, would help. He suggested that the Government should secure an increased supply of rice from Siam at an early date and said it was important that strong action should be taken to prevent the destruction by the Japanese of the world's supply of whales. Although he did not now practise, he recognized the enormous improvement in health at present compared with the condition of things after the 1914-18 war. The condition of the children on the continent of Europe in 1919 was appalling. One reason for considering that this country and the world were in a better state than at the end of the 1914-18 war was that there had not been anywhere in the world any large-scale post-war epidemic. With the exception of the U.S.A. and Canada every single country had a lower standard of food than Britain had at present and the general condition of the people was not as good as it was here. That was true everywhere, in Europe and in the East. Child health statistics, maternal health statistics, and the general health and vigour of the country showed that we were better fed now than in the inter-war period.

Dr. BARNET STROSS said that the world to-day was short of one million tons of grain and had 10% less sugar than before the war. Europe was short of meat by 40%, and the rest of the world by 10%. The world population had increased since 1938 by 5 to 10%. If the diminution in British meat supplies was 9%, then we had not done badly. They knew that between 1913 and 1934 the health of the people improved dramatically, in association with an increase in consumption of leafy green vegetables and fruit by 75% and of dairy produce by 50%. Expectation of life increased by 7 years; the death rate of infants dropped from 100 to 57; the tuberculosis rate was halved; and the children became taller, healthier, and stronger. The change continued throughout the war and to-day. The reason was that everyone had been compelled to eat less animal protein, and therefore ate much more summer fruit and leafy green vegetables. They consumed more liquid milk, and the quality of the fats was better; the vitaminization of margarine gave great protection. The better quality of bread and the fact that the nation ate more potatoes, which contained ascorbic acid, meant that the diet was healthier even though it was not fuller and was more monotonous.

### Fewer Calories

Col. ELLIOT said everyone in the House feared that the standard of living in this country was in jeopardy. Prof. Marraek had said it was unfortunate that Government spokesmen continued to claim that the average calories per head per day were in the neighbourhood of 2,900. He declared that surveys of the Ministry of Food made on representative families showed that the average per head ranged from 2,300 to 2,400. Meals taken outside could not raise the total to more than 2,650. Drs. Bransby and Magee, of the Ministry of Health (*B.M.J.*, April 19, p. 525), pointed out that classes such as farm workers, quarrymen, and lumbermen who could not get access to canteens would require, in addition to their special allowances, to eat up to 14 lb. of potatoes per week. Miners not in receipt of canteen facilities would require to eat 10½ lb. of potatoes per week or else to draw on the family pool by consuming other people's rations. The document "Food Consumption Levels" showed that about 2,800 calories per head was necessary to have an intake actually eaten of 2,500 calories per day. Yet the document further said that at

2,700 calories the diet would be too low. The nation was living on a very narrow margin. Nevertheless it was true that in the main the health records had been excellent and the dental condition of the country had greatly improved. The energy output figures made a different picture. They seemed to indicate that at present full employment was not practicable in the condition of nutrition of the people and that any reduction in the intake would lead the country into great danger. Tuberculosis figures did not bear the favourable interpretation put upon them. The death rate per million in England and Wales since 1939 was in no case as low as before the war and the notifications had gone up from 37,000 in 1938 to 42,000 in 1945. In Scotland the figures of deaths per million from tuberculosis were 520 in 1938 and 640 in 1946. Notifications in Scotland were 4,790 in 1938 and 7,500 in 1946.

Dr. STEPHEN TAYLOR pointed out that mass radiology had been introduced during the war with an increase in the notifications.

Col. ELLIOT said the nation was working on a too narrow surplus of energy intake over energy output. Its general health was good, but it found itself in difficulty in putting out a long and sustained effort such as the Government called for. Many sources of our food were in peril. The yield of fish was beginning to fall off, as happened after the first world war.

Dr. EDITH SUMMERSKILL said that the nation was adequately fed although the present diet left much to be desired in variety. She would not go into the question of calories except to quote Sir Wilson Jameson, who, in the Ministry of Health Report for the year ended March 31, 1946, which had been published seven weeks ago, said that as far as clinical surveys of the state of nutrition of groups of the population and the heights and weights of children were reliable the nutrition of the population generally remained good. Children in 1945 were of better physique than corresponding children in 1940 or before the war. She had just received figures for Scotland which showed that in 1938 the infant mortality in that country was 70 per 1,000, in 1944 65 per 1,000, and in 1946 53.8. The figures for neonatal mortality were 35 in 1938, 32.8 in 1944, and 29.2 in 1946. The maternal death rate figures were 4.9 in 1938, 3 in 1944, and 2.2 in 1946. In 1938 deaths from tuberculosis in Scotland were 69 per 100,000 population, in 1944 they were 82, and in 1946 they were 79.

Col. ELLIOT said he had quoted figures for deaths from respiratory tuberculosis.

Dr. SUMMERSKILL said pulmonary and non-pulmonary tuberculosis should be feared equally.

A motion to reduce the estimate was defeated by 278 to 113.

### Medical Members of Executive Councils

Mr. HASTINGS, on June 26, asked the Minister of Health whether, in selecting representatives of the medical profession for the local executive councils under the new Health Act, he asked for nominations from the medical committees in the various areas, and whether he knew that in not a few of these areas medical committees were elected in 1938 and there had been no election since.

Mr. BEVAN replied that appointments of medical members to Executive Councils were made by the Local Medical Committees and not by the Minister. He knew that in most areas there had not been elections for Panel Committees since 1939. Therefore his recognition of Local Medical Committees for the new Service had been provisional.

### Northern Ireland Bill

When the House of Commons on June 27 was in committee on the Northern Ireland Bill, debate arose on Clause 4, which empowers the Northern Ireland Government to provide health services. Mr. MULVEY moved a proviso that wherever the associations of a voluntary hospital linked it with a religious denomination, all attention should be paid to preserve the character and associations of the hospital in the general management and in making appointments to the board of management. The proposed amendment further provided that all endowments of such hospitals should remain their property. Mr. Mulvey pointed to a similar provision in the National Health Service (Scotland) Act, Section 60. Mr. GAGE said that a hospital in Belfast which derived strength from its religious links was one of the best hospitals in that city.

Mr. EDE said he understood that the Northern Ireland Government decided to follow Section 61 of the English Act, which incorporated the principle of the first proviso. Parliament had refused to insert the principle of the second proviso in either the English or the Scottish Bill.

Mr. Mulvey withdrew his amendment.

The Report stage was concluded and the Bill was read a third time.

### Typhoid at Bombay

Mr. PHILIP NOEL-BAKER stated on July 2 that in 1946 there were 32 cases of typhoid at Worli camp, Bombay; this year there had been 11 cases. In 1946 one man died; on grounds of conscience he had refused inoculation. As soon as the water supply was found to be infected all drinking water was chlorinated in mobile tanks. New mains were installed last December. Analysis had shown that the water was now free from all infection, but as an additional precaution the mobile tanks were still in use.

### Voluntary Funds

Asked on July 3 by Mr. SPARKES to state his attitude toward the continuance of such voluntary efforts as fêtes, bazaars, and sales of work for the benefit of particular hospitals, Mr. BEVAN said the governing bodies would have power to receive and hold voluntary funds from any source independently. No charges could be made on patients for any part of the service except those specifically mentioned in the Act or Regulations. Each of the hospitals could raise funds for additional purposes such as welfare. During the Committee and Report stages of the Bill he had made it clear that hospital committees could themselves organize voluntary funds under the new arrangement. These funds would in no way diminish the revenue provided by the State.

### Signing of Death Certificates

Mr. SPARKES asked on July 3 what precautions were taken to secure that the cause of death certified upon a death certificate was correct; and, in view of the evidence at the recent coroner's trial at Southport, what steps Mr. Bevan proposed to take to ensure that death should not be certified from wrong or false causes. Wing-Commander HULBERT inquired if Mr. Bevan was aware that the law now permitted medical practitioners to issue death certificates in respect of near relatives, and if he proposed to introduce legislation to amend this practice.

Answering both questions, Mr. BEVAN said that the position under the Births and Deaths Registration Acts and Regulations was that a registered medical practitioner who was otherwise competent in the circumstances of the particular case to give a certificate of the cause of death was not precluded from doing so by reason of relationship to the deceased. It was not open to the registrar of births and deaths to reject a certificate on that ground. The duties of the registrar included the duty to report to the coroner, before registration, deaths in specified categories, including any which he had reason to believe to be unnatural or accidental, or attended by suspicious circumstances, or the cause of which appeared to be unknown. Mr. Bevan added that at present he did not contemplate amending legislation on any of these matters. He had no comment to make on the circumstances of a recent case at Southport and would not derive a general conclusion from that particular instance.

Mr. HECTOR HUGHES suggested that death certificates should be countersigned by an independent practitioner. Mr. Bevan repeated that he did not contemplate any amendment of the law at present.

**Nurses.**—On Jan. 1, 1946, the number of State registered and enrolled assistant nurses in Scotland was 17,767. On May 31, 1947, the number was 20,858. The numbers of women who became student nurses in Scottish hospitals during 1945, 1946, and the first five months of 1947 are estimated as 2,500, 3,200, and 1,300.

**The Deaf Blind.**—All blind-welfare authorities provide for the visitation and instruction of deaf-blind persons by home teachers.

## The Services

The Air Force Cross has been awarded to Acting Wing-Commander R. Maycock, R.A.F.

The following appointments and mentions in dispatches in recognition of gallant and distinguished services in the Netherlands East Indies prior to Nov. 30, 1946, are announced:

**O.B.E. (Military Division):** Miss Perin K. Mullaferoze, F.R.C.S., Lieut.-Col. (temporary); Lieut.-Col. (temporary) S. L. Rikhye, M.B.E., I.M.S.

**M.B.E. (Military Division):** Captain (temporary) Lal Chand, I.A.M.C.

**Mentions in Dispatches:** Brigadier (temporary) G. S. Douglas, late R.A.M.C.; Lieut.-Cols. (temporary) B. Blewitt and V. J. Keating, R.A.M.C.; Capt. H. Foster, R.A.M.C.; Lieut.-Col. (temporary) G. Ahmed, I.A.M.C.; Majors (temporary) K. R. Ramo Rao and M. R. K. Siddique, I.A.M.C.

No. 25

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 21.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Smallpox

At Barnsley, after an interval of four weeks, the sixteenth case was detected and removed to hospital on June 30. The diagnosis has been confirmed by the recovery of variola virus on egg culture. The patient is a woman aged 62, vaccinated in infancy and during the 1914-18 war. She is suffering from a modified attack which began on June 24. A discrete rash appeared on June 28. The source of infection is at present undetermined.

At Bilston a schoolboy aged 10 was removed on July 2 on suspicion. A rash had appeared on the previous day. He had been vaccinated on June 23. Confirmation of diagnosis is not yet available.

## Poliomyelitis

Notifications for the week ending June 28 show a further increase to 56, compared with 44 in the previous week and 8 in the corresponding week of 1946. The disease is widely scattered over the country, some three dozen sanitary districts being involved.

## Polio-encephalitis

Polio-encephalitis notifications have also jumped to 11 from an average of 2 to 3 a week. It is not yet known whether this rise is merely a reflection of the incidence of poliomyelitis or whether there is in fact a prevalence of encephalomyelitis and encephalomeningitis distinguishable from anterior poliomyelitis and resembling the series of cases described by Jennings (*Lancet* 1947, 1, 471). An increase in cerebrospinal fever notifications to 57 may have some significance in this connexion.

## Notification of Puerperal Fever to Cease in London

The London County Council is proposing to promote legislation next session to provide that puerperal fever shall cease to be a notifiable infectious disease and a dangerous infectious disease for the purpose of the Public Health (London) Act, 1936. In the provinces puerperal fever was notifiable up to September, 1937, under the Infectious Diseases (Notification) Acts, but these were repealed by the Public Health Act, 1936, and the disease was omitted from the list of notifiable diseases in section 343 of that Act. Puerperal pyrexia is notifiable in London under Regulations issued in 1926 and 1928 by the Ministry of Health, and in the provinces under Regulations issued in 1939, which, except in London, replaced the earlier ones. The Regulations are difficult to understand, and the statistics obtained on the present basis have been found valueless. As the separate notification of puerperal fever in London is not found to serve any useful purpose, it is considered that the Public Health (London) Act should be amended by the removal of puerperal fever from the list of notifiable infectious diseases and also from the list of dangerous infectious diseases. This will leave puerperal pyrexia to be dealt with solely by Regulations of the Minister under the Public Health Act, 1936, and by orders of the L.C.C. and the sanitary authorities under the London Act.

## Discussion of Table

In England and Wales there was an increased incidence of whooping-cough 45, scarlet fever 37, diphtheria 25, while a decrease was reported for measles 164 and acute pneumonia 52.

The returns for scarlet fever and whooping-cough for local areas showed only small variations from the total notifications of the preceding week. The only large fluctuation in the local incidence of diphtheria was an increase of 25 in Lancashire, these cases being dispersed throughout the county and not due to a localized outbreak. The downward trend in the notifications of measles ceased in several counties, the largest increases being London 122, Glamorganshire 107, Sussex 104; the only large decreases were Yorkshire West Riding 432 and Surrey 130.

Although the total number of notifications of dysentery were practically unchanged, the cases were more widely dispersed. The 47 cases were notified in 21 counties—compared with 48 notifications from 14 counties in the preceding week. All the cases of smallpox notified were from Bilston U.D., Staffs. There were 44 cases of poliomyelitis—an increase of 13 on the high level of the preceding week—involving 21 counties. The only area with a number of cases was Barrow-in-Furness C.B., Lancs., where 5 cases were notified.

In Scotland there was an increase in the notifications of acute primary pneumonia 60, and scarlet fever 24, while decreases were recorded for measles 34, whooping-cough 21, dysentery 20, and cerebrospinal fever 8.

In Northern Ireland the chief features of the returns were increased incidence of measles 10, scarlet fever 5, and diphtheria 4. Six cases of typhoid fever have been notified in Belfast up to June 26.

CONTROL

THE  
OVERACTIVE  
THYROIDWITH  
**METHYL THIOURACIL**  
(‘GENATOSAN’)

Evidence is now accumulating that Methyl Thiouracil (‘Genatosan’) will control the thyrotoxic state more satisfactorily than will Thiouracil. Where, because of tracheal obstruction, or for cosmetic reasons, subtotal thyroidectomy is necessary, Methyl Thiouracil (‘Genatosan’) may be used in conjunction with iodine to prepare the patient for surgery.

**Something entirely NEW  
in ELASTIC STOCKINGS**

These points make Lastonet the ideal Surgical Stocking:—

- ★ Made from light - weight, washable elastic net, they combine minimum weight with full support.
- ★ Net construction allows the air to circulate freely over the skin, making the stocking cool and comfortable to wear.
- ★ Despite the very heavy demand for Lastonet, we shall continue to give the best possible delivery
- ★ Every stocking is made-to-measure in full or knee-length. Measurement forms are obtainable from leading chemists or, in case of difficulty, direct from the makers.
- ★ Lastonet is invisible under the normal stocking.

FOR

**PAIN, SWELLING,  
SORENESS**

In the treatment of boils or other localized infections where “Moist Heat” is indicated, the “Moist Heat” of ANTIPHLOGISTINE helps relieve pain, swelling and soreness.

Applied comfortably hot, ANTIPHLOGISTINE supplies “Moist Heat” for several hours. ANTIPHLOGISTINE may be used with chemotherapy.

The “Moist Heat” of ANTIPHLOGISTINE is also effective in relieving the pain and swelling of a sprain, bruise, or similar injury or condition.

## invented by Doctor . . .

**TAMPAX**, first introduced in 1934, was the direct adaptation by a practising Doctor of the principle of the surgical tampon to the absorption of the menstrual flow. As such, it received the approval of the medical profession, not only for its alleviation of mental stress and physical discomfort but for its hygiene and absolute safety—ensured by the Tampax patent stitching process which

positively prevents disintegration. Today that approval is world-wide. Tampax is recognised as both the pioneer and the best form of sanitary protection worn internally. If you are not receiving copies of the new series of medical leaflets now being despatched, or require a sample packet of Tampax, please write to: Medical Inquiries, Tampax Ltd., 110 Jernyn St., London, S.W.1.

*Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymeneal aperture would cause difficulty in insertion and withdrawal.*

Sanitary Protection

**TAMPAX**

Worn Internally

has won the approval of Doctors everywhere

TAMPAX LTD., BELVUE ROAD, NORTHOLT, MIDDLESEX.

# B.D.H.

## PENICILLIN OIL-WAX SUSPENSIONS

In general practice intramuscular injection of an oil-wax suspension constitutes the most convenient method for systemic administration of penicillin.

The comparatively low viscosity of Penicillin Oil-wax Suspension (Ethyl Oleate) B.D.H. facilitates administration without preliminary warming and an unduly wide bore needle is not required.

## The Sunday Times

DID YOU KNOW that the *Sunday Times* offers you the most distinguished group of contributors in British journalism? Just glance at this list—

Norman Crump and G. L. Schwartz on Finance and Industry; "Scrutator" on World Affairs; Charles Gayton on Politics; Ernest Newman on Music; Harold Hobson on the Theatre; Delys Powell on Films; Eric Newton on Art; Desmond McCarthy,

Charles Morgan and Ralph St on Books; "Atticus" on Women and Memories"; S Correspondents on Moto Yachting, Hunting, Acrona Hugh Wynne on Cricket; Delane on Women's International special photographs and dra by J. Dixon-Scott and ff Fletcher.

If you are unable to obtain *Sunday Times*, write to The Lisher, Kemsley House, W.C.1

In *Eire* notifications of diphtheria increased by 9, while those of diarrhoea and enteritis fell by 8. The 24 cases of diphtheria were mainly isolated cases and involved 18 registration areas.

### Week Ending June 28

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 947, whooping-cough 2,052, diphtheria 182, measles 9,377, acute pneumonia 342, cerebrospinal fever 57, acute poliomyelitis 56, dysentery 66, smallpox 2, paratyphoid 10, typhoid 10.

## Universities and Colleges

### UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

M.D.—S. B. Rampling.

FINAL M.B., Ch.B.—Barbara Anderson, Margaret Bagshaw, Mary L. Barrett, J. Bengier, J. I. Beniley, P. Brooks, D. L. Chadwick, Elizabeth H. Clow, Sheila A. Costello, P. J. Croxford, L. Dawson, J. Dubberley, R. D. P. Eaton, G. Fairclough, I. Feingold, J. R. C. Fleet, P. D. Fowler, S. E. Gilbert, Ruth Goodier, B. Goodman, K. S. Holt, Christine M. Hope, Thelma B. Hoyle, A. K. Karfoot, I. P. Kirby, N. P. Lancaster, W. Lees, D. C. Lindars, \*Muriel Lister, G. P. Love, H. C. Lowe, A. T. Mason, J. G. Mathie, H. L. Matthews, J. O. Miller, J. H. Mulliner, A. Murphy, J. Nagington, J. A. Nightingale, L. M. Norburn, J. Rimington, S. L. Royce, Margaret E. R. Stoneman, D. B. Stott, C. H. Thompson, J. T. L. Unsworth, G. W. Waters, \*Lettitia E. Woodvine. *Part I: Forensic Medicine and Hygiene and Preventive Medicine*: Barbara Anderson, Margaret Armistead, Doreen N. Ashworth, Ben J. G. R. Attwood, H. de C. Baker, M. Bernstein, F. B. Beswick, Margery F. Blumberg, Joan Bolton, P. H. Broadwell, A. Braddock, A. B. Bradshaw, M. A. Brennan, Dorothy E. N. Briggs, J. Broadhurst, R. W. Buckley, F. Connor, Nancy M. Cessetti, J. L. Cotton, J. G. Cottrell, J. A. L. Derrin, M. Fasnacht, G. E. Fleetwood, D. L. Fox, B. Gill, Barbara Hall, Barbara C. Hanson, B. Hendy, D. D. Hilton, Constance M. Jorrock, Muriel M. Hughes, J. D. Hunt, H. Jackson, Jean Kershaw, Alexandra J. Climan, Freda W. Lunt, C. A. Mays, Winifred J. Millar, S. Panikkar, K. M. Pearce, Dorothy Pearson, S. D. Pratt, K. Rawnsley, Regina Reif, Patricia Rhodes, N. R. Riley, Jean M. Sheldon, Beatrice E. Sleight, L. Smith, P. J. D. Snow, J. A. Steele, B. Stone, Ruth Tattersall, D. B. S. Taylor, I. G. Taylor, R. M. Taylor, Helen L. S. Tennent, W. L. Tonge, J. B. D. Torr, K. Tuxford, J. D. Millers, D. L. Watson, H. Weiss, Doreen Wilkinson, J. L. Wilkinson, B. L. Williams.

\* With second-class honours. † Awarded distinction in obstetrics.

M.D.—*Part II*: H. A. Cole, R. Cotter, Kerr, M. G. McColl. *Part I*: C. L. Casimir, E. Smith.

### UNIVERSITY OF DUBLIN

#### SCHOOL OF PHYSIC. TRINITY COLLEGE

The following medical degrees were conferred on July 2:

M.D.—W. P. Griffin, P. Jabkovitz, H. D. McGorry, L. L. Nel, A. E. B. de Courcy Wheeler.

M.Ch.—G. E. Nevill.

M.B., B.Ch., B.A.O.—H. A. Adams, A. D. H. Browne, C. R. Deuchar, Marion F. Gaston, M. V. Graham, E. R. Haynes, Evelyn M. Holberton, Monica A. Jackson, A. J. E. Kilpatrick, F. Kirkpatrick, G. B. Leitch, E. A. McColl, J. M. McCormick, R. M. Peet, Marjory A. Pollock, M. S. Strong, Elisabeth M. Wann, Ruth R. Watson, J. L. Wilkinson, I. Wilson.

### UNIVERSITY OF GLASGOW

James Norman Davidson, M.D., D.Sc., professor of biochemistry in the University of London, has been appointed to the Gardiner Chair of Physiological Chemistry in the University of Glasgow, in succession to Prof. G. M. Wisbart.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

#### ELECTION TO THE COUNCIL

On July 3 Mr. R. J. McNeill Love was re-elected and Mr. A. Lawrence Abel and Mr. J. B. Oldham were elected members of the Council of the College. In addition Sir James Walton received the requisite number of votes but is prevented by the terms of the 1947 Charter from taking his seat on the Council as he has already served for sixteen years. There will, therefore, be a vacancy until the next election. The Fellows elected were:

	Votes
Robert John McNeill Love (Royal Northern) ..	839
Sir James Walton (London) ..	835
Arthur Lawrence Abel (Princess Beatrice) ..	637
James Bagot Oldham (Royal Liverpool United)	629

The following were the other candidates:

Arthur Dickson Wright (St. Mary's) ..	609
Hubert Wallace Symons (General Infirmary at Leeds) ..	557
Harold Clifford Edwards (King's College) ..	478
Louis Carnac Rivett (Middlesex) ..	356
Marriott Fawcner Nicholls (St. George's) ..	277

In all 1,563 Fellows voted: in addition six votes were found to be invalid.

## Medical News

### The Association of Surgeons

The Association of Surgeons of Great Britain and Ireland held its annual dinner in the Hall of Christ Church, Oxford, on July 3 with the President, Sir Hugh Cairns, in the chair. Prof. Geoffrey Jefferson, F.R.S., proposing the toast of the Association, quoted Southey and Spratt as witnesses against the volubility of those who make public utterances. In referring appreciatively to some of the early members of the Association of Surgeons, he said that a man who was incapable of worshipping heroes was lacking in one of the great qualities of the human spirit. Those who with Moynihan had started the Travelling Surgical Club had as one of their aims the breaking down of the jealousy unfortunately characteristic of surgeons in some other countries. Prof. Jefferson coupled the toast with the name of the President. In response Sir Hugh Cairns gratefully acknowledged the hard work done by the Hon. Secretary of the Association, Mr. H. W. S. Wright, and its Hon. Treasurer, Mr. R. M. Handfield-Jones. He paid a tribute to the memory of two absent friends—the late Mr. Tudor Edwards, who is now commemorated in the Tudor Edwards Travelling Fellowships in Thoracic Surgery; and the late Hugh Whitelocke. Sir Hugh gave a message of welcome to the Association from Dr. Elliot Cutler. He spent some time in discussing the evolution of the Nuffield Clinical School of Medicine in Oxford. He pleaded that they should not aim at producing a standard type of surgical professor, and that they should avoid excessive regimentation and standardization in their schools. Sir Alfred Webb-Johnson, in a characteristically humorous speech, proposed the health of the guests, welcoming in particular those from other countries: Prof. René Leriche, Prof. H. E. F. Albert, Prof. R. Danis, Prof. J. de Faumestreaux, Dr. Lortat-Jacob, Prof. L. Mayer, Prof. J. Morelle, Dr. L. Bazy, Prof. W. Noordenbos, and Dr. W. K. Livingston. He thanked those whom he described as their hosts and guests: Sir Richard Livingstone, Vice-Chancellor of Oxford University; and the Dean of Christ Church. It was fitting, he said, that Sir Hugh Cairns, as a Rhodes scholar, should hold the first Commonwealth Travelling Fellowship. Sir Alfred paid a handsome tribute to their benefactor, Lord Nuffield, whom Sir Hugh Cairns had described earlier as "the Cowley father of modern medicine." Responses were made on behalf of the guests by Sir Richard Livingstone and by Prof. René Leriche.

### More Nurses

Presenting medals and certificates at the Middlesex County nurses' examination on June 20, the Minister of Health said that more girls were entering the nursing profession now than before the war—about 14,000 annually compared with something over 11,000. Under the National Health Service two developments that would help to provide the best possible training for nurses would be wider facilities made available by the regionalization of hospitals and the fact that the desirability of full student status for the nurse in training was becoming increasingly recognized.

### Dental Surgery at Glasgow

Sir Hector Hetberington, Principal of Glasgow University, announced at the annual prize-giving ceremony on June 27 at the Glasgow Dental Hospital and School that the University had taken over the control of dental education in Glasgow and would institute a degree in dental surgery. The University will select next year's entry of students to the Dental School.

### Free Supplies for Day Nurseries

Every child attending a day nursery both in the morning and in the afternoon is now allowed two-thirds of a pint of liquid milk (or national dried milk when necessary) free of charge. Free cod-liver oil (6 oz. for 12 weeks) and a bottle of orange-juice (price 5d.) every 4 weeks is also allowed. Day nurseries should register for benefit under the Welfare Foods Service as set out on Form WF/DN.15, obtainable from the Ministry of Food. A day nursery not administered by a welfare authority should submit this form to the medical officer of health for certification that it is entitled to receive benefit. The local food office will then make the necessary arrangements. The milk benefit is applied for on Form WF/DN.4, which is renewable at quarterly intervals and obtainable from local food offices. The source and quality of the liquid milk must be approved by the medical officer of health.

### Called to the Bar

Jeffrey Murray Robertson, M.B., B.S. (Inner Temple), and Thomas Kemp Homer, M.B., Ch.B. (Gray's Inn), were called to the Bar on June 18.

## Wills

Dr. John Wallace, of Weston-super-Mare, who died on Feb. 13, aged 90, left £32,846. Mr. Christopher Tredwell Holford, of Tiverton, Devon, formerly senior surgeon of Burton-on-Trent Infirmary, left £34,492. Dr. George Montgomery Drury, of Cheadle Heath, Stockport, left £2,372. Mr. Walter Graham Stewart, of Ware, Herts, left £26,548. Sir Richard Robert Cruise, surgeon oculist to King George V and to Queen Mary, owner of the famous steeplechaser War Gratuity, left £40,215. Sir Walter Langdon-Brown, of Cambridge, left £23,630. Mrs. Catherine Mabel Ederley, of Menston, Yorks, one of the first women to qualify and an authority on the Brontes, left £29,533.

## COMING EVENTS

## Athletics

The City and Hospitals Charity Athletic Contest for the *Financial Times* Challenge Shield is being held at the London University Sports Ground, Motspur Park, Surrey, on July 12. The first event is at 3 p.m. Admission at the gate is 1s. 6d.

## Labour Saving Hospitals

An exhibition of labour-saving devices for use in hospitals will be opened by the Minister of Health on July 14 at 3 p.m. at the Empire Tea Centre, 22, Regent Street, London, S.W.1. It has been organized on behalf of the Ministry of Health by the British Electrical Development Association and the British Gas Council. Exhibits will include special cleaners and polishers, a bed-pan sterilizer, cooking utensils and ice-cream makers, laundry apparatus, and suggestions for brightening the domestic staff's private rooms. The exhibition is open in the morning only to hospital representatives, and to the public every afternoon from 1-5.30 p.m. It will close on Aug. 2.

## The Physiology of Lactation

The Kent Paediatric Society has arranged for Dr. H. Waller to give two addresses on "The Physiology of Lactation and the Causes of Early Failure" at the County Hospital, Farnborough, on Tuesdays, July 15 and 22, at 8 p.m. Hospital paediatric and maternity nurses, midwives, and health visitors are invited to attend the lectures.

## Kelynaek Memorial Lecture

Prof. F. L. Golla, F.R.C.P., director of the Burden Neurological Institute, will deliver the inaugural Kelynaek Memorial Lecture on "Alcohol and the Neuroses" before the Society for the Study of Addiction at Westminster Hospital Medical School, Horseferry Road, London, S.W., on Tuesday, July 15, at 4 p.m.

## Tuberculosis Conference

The joint annual conference of the Tuberculosis Association and the Tuberculosis Society of Scotland will be held in the Department of Zoology, King's Buildings, West Mains Road, Edinburgh, on July 16, 17, and 19. The programme is as follows: July 16, 10 p.m., opening address by the Marchioness of Linlithgow; 4.5 p.m., Dr. H. A. Pattison (New York), "Rehabilitation in the U.S.A."; 4.45 p.m., discussion, to be opened by Mr. T. Holmes Sellers, "Assessment of the Results of Thoracoplasty," followed by a general discussion in which several thoracic surgeons will give brief reviews of their results; 8.15 p.m., annual general meeting of the Tuberculosis Association; 9.15 p.m., Dr. H. P. Tait, "Edinburgh Medical Men at the Time of the Resurrectionists." July 17, 9.30 a.m., Dr. H. Van den Berg (Amsterdam), "The Control of Results in B.C.G. Trials"; 11 a.m., Dr. J. G. Scadding, "The Pneumonias Associated with Epidemic Respiratory Infections"; 2 p.m., Dr. V. Reilly, "The Pathology of Amyloidosis"; 3 p.m., Dr. W. M. Borthwick, "Genito-urinary Tuberculosis"; 4.45 p.m., Prof. V. Monaldi (Naples), "Endocavitary Aspiration in the Treatment of Pulmonary Tuberculosis"; in the evening there will be a special performance of "The Anatomist" in the Little Theatre. July 19, 9.30 a.m., Mr. Norman Dott, "Skeletal Traction, Surgical Decompression in the Management of Pott's Paraplegia"; 11 a.m., discussion on "The Causes of the Breakdown of Discharged Quiescent Cases," to be opened by Dr. Alex. MacLean and Dr. B. R. Clarke. July 18 will be devoted to recreation, with a golf match at Gullane, an excursion to the Border country, and a garden party in the afternoon; in the evening there will be a joint annual dinner, preceded by a reception at the Grand Lodge of the Freemasons.

## Penicillin Treatment of Syphilis

A joint meeting of the Medical Society for the Study of Venereal Diseases and the Section of Experimental Medicine and Therapeutics of the Royal Society of Medicine will be held at 1, Wimpole Street, London, W., on Thursday, July 17, at 5.15 p.m., when a discussion on "The Treatment of Syphilis with Penicillin" will be opened by Dr. Earle Moore (U.S.A.), Dr. G. L. M. McElligott, and Dr. E. M. Louric.

## Modern Anaesthesia

Dr. I. W. Magill has accepted the invitation of the Royal Institute of Public Health and Hygiene (28, Portland Place, London, W) to be the Bengué Memorial Award Lecturer for 1947. His subject is "A Review of Modern Anaesthesia," and the lecture will be delivered at the institute on Thursday, July 17, at 3 p.m. Admission is free, without ticket. Seats may be reserved upon application to the secretary of the Institute.

## APPOINTMENTS

Dr. Vincente Banet and Dr. José Lastra have been appointed president and vice-president respectively of the National Society of Surgery of Cuba.

Mr. J. F. Foster, formerly registrar of the University of Melbourne and secretary of the Australian Vice-Chancellors' Committee, has been appointed secretary of the Universities Bureau of the British Empire, on the retirement of Mr. W. B. Brander.

Dr. P. S. Selwyn-Clarke, C.M.G., M.C., has been appointed Governor and Commander-in-Chief of the Colony of Seychelles.

John Watkins-Pitchford, M.D., has been appointed H.M. Inspector of Factories.

BIRMINGHAM: SELLY OAK HOSPITAL.—Chief Assistant Surgeons, A. R. Leach, F.R.C.S., J. R. A. White, F.R.C.S.Ed., G. R. Clarke, F.R.C.S.Ed., Chir. Assistant Physicians, W. M. Philip, M.B., M.R.C.P., W. P. U. Jackson, M.D. M.R.C.P., I. A. Guest, M.D., M.R.C.P., Chief Assistant Gynaecologist and Obstetrician, M. L. Neville, M.B., D.R.C.O.G., Anaesthetist, T. H. Hobbes, M.B., D.A., Resident Assistant Anaesthetist, J. E. McCutcheon, M.B., Ch.B., BLACKWOOD, WILLIAM, M.B., F.R.C.S.Ed., Assistant Pathologist, National Hospital, Queen Square, London, W.C.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford, E.—Honorary Assistant Obstetric Surgeons, H. H. Fouracre Barnes, F.R.C.S., and B. G. Spier, F.R.C.S.Ed.

REES, HARLAND, M.Ch., F.R.C.S., Surgeon, St. Peter's Hospital for Stone, Henrietta Street, London, W.C.

SEYMOUR-JONES, ANTHONY, F.R.C.S., D.L.O., Honorary Assistant Surgeon to Ear, Nose, and Throat Department, Portsmouth and Southern Counties Eye and Ear Hospital.

## SOCIETIES AND LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W. Tuesday and Thursday, July 15 and 17, 5 p.m. Humphry Davy Rolleston Lectures by Dr. P. C. P. Cloake: Treatment of Disseminated Sclerosis by Artificial Pyrexia and Prolonged Administration of Arsenic.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Thursday, July 17, 6.15 p.m. Charles Tomes Lecture by Prof J. G. Turner: Movements of Teeth.

## ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—Tuesday, July 15, 5.30 p.m.

Section of Experimental Medicine and Therapeutics.—Thursday, July 17, 5 p.m. Annual general meeting: Election of Officers and Council for 1947-8. 5.15 p.m. Joint Meeting with the Medical Society for the Study of Venereal Diseases. Discussion: The Treatment of Syphilis with Penicillin. Openers: Drs. Earle Moore, G. L. M. McElligott, and E. M. Louric.

BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, London, W.—Thursday, July 17, 8 p.m., Twenty-fourth Mackenzie Davidson Memorial Lecture by Dr. John H. Lawrence (University of California): Application of Artificial Radioactivity to Biology and Medicine.

MEDICAL SOCIETY OF LONDON, 11 Chandos Street, W.—Monday, July 14, 8.30 p.m. Mr. F. A. Williamson-Noble, Contact Lenses; Dr. G. B. Dowling, Athlete's Foot; Mr. A. Dickson Wright, Pruritus Ani.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words at first. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

## BIRTHS

BEALE.—On June 27, 1947, at Bridgwater, to Violet, wife of Dr. J. Hanway Beale, a daughter.

## MARRIAGES

BROWN—DANOS.—On June 25, 1947, Arthur Edward Brown, L.R.C.P., M.R.C.S., D.P.H., and Irene Danos, Budapest, Hungary.

EVANS—MORE.—On May 31, 1947, at Ipswich, Gordon M. Hylton Evans, M.R.C.S., L.R.C.P., to Hannah Mary More, S.R.N.

ILLINOWORTH—REDHEAD.—On July 3, 1947, in Newcastle-upon-Tyne, Professor Ronald Illinoworth, M.D., F.R.C.P., D.P.H., D.C.II., to Cynthia Mary Redhead, M.B., B.S., M.R.C.P.

LOVETT—HARRY.—On July 5, 1947, at Peterstone-super-Ely, Glamorgan, William Charles Donald Lovett, B.Sc., M.B., B.Ch., B.S., to Frances Mary Harry.

RUTTER—STEVENS.—On July 5, 1947, at Caxton Hall, London, S.W.1, Clarence Rutter, M.R.C.S., L.R.C.P., to Mrs. Mary Stevens.

WALTERS—LARGE.—On June 30, 1947, in London, Geoffrey A. Bagot Walters, F.R.C.S.Ed., to Mrs. Daphne Large (née Pullin-Thompson).

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Acute Poliomyelitis

**Q.**—I am of the opinion that acute anterior poliomyelitis is related to gastro-intestinal infection, and that the main essential treatment is complete evacuation of the alimentary tract. Constipation is usual, but in the few cases where diarrhoea has occurred I regard this as the attempt of a healthy bowel to expel toxins. Is my theory correct?

**A.**—Recent evidence has shown that the virus of poliomyelitis appears in the faeces for some days or even weeks after onset of the infection, and that the virus probably reaches the central nervous system from the bowel, since it has been demonstrated in the abdominal sympathetic ganglia. In the pre-paralytic stage of the infection, characterized particularly by fever and irritability, gastro-intestinal symptoms may be present, although they are not usually prominent features. The modern view is that the majority of patients affected with the virus of poliomyelitis develop only these pre-paralytic symptoms, and these cases are called "abortive" poliomyelitis. What determines the development of the paralytic stage in the minority of cases is still unknown, although severe muscular exercise is probably an important predisposing factor. It seems unlikely that purgation or the natural occurrence of diarrhoea in the early pre-paralytic stage will affect the course or severity of the infection.

### Physics of Odour

**Q.**—Is anything known about the physics of odour? We know that sensations of smell are conducted from the olfactory nerve endings, but how do they get there? What sort of particles does the smelling substance emit, and how do they traverse the air? Has any measurement been made of the air content of odoriferous particles? Does an odoriferous substance decrease in weight as a result of emission of such particles? Can they be seen or cultivated?

**A.**—There is a general belief that material particles of odoriferous substances must come into contact with the olfactory receptors and that the actual stimulation is due to some chemical action. There can be no doubt that the odoriferous substance is carried in the air, but very small weights of such substance may scent a room for years without apparent loss of weight. Threshold concentrations have been measured for some substances, but naturally the threshold varies for different individuals and in the same individual from time to time, but the following threshold concentrations are given: skatol,  $3 \times 10^{-11}$ ; synthetic musk,  $4 \times 10^{-11}$ ; mercaptan,  $3 \times 10^{-9}$  % in air (w/w). The loss of weight of a substance required to give these concentrations in usual surroundings, say a room, although exceedingly minute is nevertheless calculable.

### Ichthyosis

**Q.**—A patient with severe ichthyosis from birth has seemed more normal during hot weather and especially in the Tropics. After return from the Tropics the skin became as bad as ever. On a course of thyroid extract he appeared to be sweating more and his skin became more scaly than usual, but the scales desquamated leaving the skin smooth and almost normal. How much thyroid can I give him, and for how long, apart from looking for symptoms of hyperthyroidism? Will prolonged dosage do harm and will any children be adversely affected? His brother has the same complaint, and his mother has a rough skin but no scaling. Can you suggest any other form of treatment?

**A.**—Ichthyosis is a congenital abnormality of the skin, often familial, and cannot be permanently influenced by treatment, though some little change occasionally occurs at puberty or the menopause. Thyroid by mouth increases metabolism and sweating and so may produce symptomatic improvement while

the drug is being administered. As a general rule it is wiser to control ichthyosis by local treatment, such as warm baths and the use of the following ointment:

R		
Acid. salicyl.	.. ..	gr. 10 (0.65 g.)
Lanolin.	.. ..	
Ol. oliv.	.. ..	
Glycerin.	.. ..	āā ad 1 oz. (30 g.)
Halden's emulsifying base	.. ..	
Paraff. moll.	.. ..	
	Ft. ung.	

There is probably no harm in the prolonged administration of thyroid extract in reasonable dosage, to a total of not more than 1 to 2 gr. (65 to 130 mg.) a day, but it would seem unjustifiable to give larger doses unless there was any indication otherwise of thyroid deficiency. The affection is one that tends to be inherited, and reference should be made to *Inherited Abnormalities of the Skin*, by E. A. Cockayne (1933, Oxford University Press, London).

### Chronic Bronchitis and Emphysema

**Q.**—A man of 72 is subject to chronic bronchitis and emphysema. The attacks started twenty years ago and have since increased in severity and frequency. Iodides, stramonium, and ephedrine have given only temporary relief. Recently it has been necessary to take ephedrine tablets daily, though the effect is less marked than before. X-ray examination of chest is negative. What do you advise?

**A.**—This description suggests that the patient has chronic bronchitis with attacks in which bronchial spasm is superimposed. In this disorder dyspnoea in the early stages is due mainly to bronchospasm and is relieved by ephedrine. With the passage of years irreversible changes occur in the lung parenchyma, diminishing its elasticity; it is to these that the dyspnoea of the later stages must be ascribed. The history reveals this change, for a dyspnoea on effort is gradually grafted upon, or replaces, the episodic asthmatic breathlessness. Treatment at this late stage is difficult and often unavailing, but the most useful therapeutic measure is the education of the patient, by means of breathing exercises, to use his damaged respiratory apparatus in the most efficient manner possible.

### Vitamin D<sub>2</sub> and Pyrexia

**Q.**—Can concentrated vitamin D<sub>2</sub> cause pyrexia, as well as digestive disturbances? A young woman with pulmonary tuberculosis of four years' standing recently became sputum-positive without increase in radiological signs and with no obvious temperature disturbance. She had a course of calcium and vitamin D<sub>2</sub>, but after the sixth dose of the latter pyrexia and general malaise developed. The vitamin was discontinued and after eight or nine days the temperature subsided. Was this coincidence, or could the vitamin treatment have influenced this phase of pyrexia?

**A.**—Pyrexia has not been reported in patients not suffering from tuberculosis given massive doses of vitamin D. Side-effects such as sweating, nausea, vomiting, anorexia, headache, diarrhoea, and polyuria have been reported after taking very large doses—for example, more than 200,000 units daily over a period. It is not stated in the question how much vitamin D<sub>2</sub> was taken. As the pyrexia occurred only after the sixth dose of vitamin D<sub>2</sub>, and as toxic effects result only after prolonged administration of large doses, it is unlikely that the pyrexia in this case was caused by the vitamin.

### Gastric Analyses

**Q.**—Much time is occupied in carrying out large numbers of gastric analyses with test meals. I believe that as much information could be obtained from the fasting juice, after previous preparation of the patient by a stomach wash-out, etc., followed by examination of a sample after administration of histamine if free hydrochloric acid is not found in the fasting juice.

**A.**—Gastric secretion is a valuable function which may be influenced by many different circumstances. The ordinary fractional test meal is open to so many possible errors that its

value as a diagnostic procedure in cases of uncomplicated peptic ulcer is doubtful. In the investigation of a patient with an anaemia or suspected carcinoma of the stomach, however, a secretion test may be important, and in these instances it is the presence or absence of hydrochloric acid which is looked for. Preliminary lavage may interfere with the secretion of gastric juice and therefore should not be done. No test meal is given, but specimens must be withdrawn at regular frequent intervals for two hours after the injection of histamine, otherwise a minimal response may be missed.

### Femoral Thrombosis

**Q.**—A woman of 64 had a left femoral thrombosis a year ago, caused by confinement to bed for kraurosis vulvae. She is now quite well except for the leg, which becomes swollen and painful with even mild exercise. What treatment do you advise, and what are the prospects of recovery?

**A.**—The condition having settled down, it only remains to deal with the swelling which is the cause of the pain. Bandaging with real elastic bandages (not crêpe) will keep down the swelling below the knees, and that usually suffices. Raising the foot of the bed at night is also very helpful in reducing swelling and cramp. The amount of residual swelling is often greatly reduced by lumbar sympathetic procaine blocks during the active phase of thrombosis, but unfortunately in the present case the opportunity for this helpful procedure has now passed.

### Pediculosis Capitis

**Q.**—For three months I have been treating a friend who has pediculosis capitis with this mixture: "Lethane 384," 49 parts; ol. petrol. alb., 49 parts; ol. citronel., 2 parts. This has been applied four to six evenings a week after careful removal of nits, but has had no effect beyond reducing the nit population and alleviating scalp irritation. My friend deals with large numbers of children and has taken precautions against re-infection. Can you suggest a reason for the failure of this treatment, and is there one more likely to succeed?

**A.**—Some millions of cases of pediculosis capitis have been treated with lethane, and where this has been properly carried out the writer does not know of one instance where three applications have not been completely successful and have not also prevented re-infection. The vast majority of individuals were cured with one application. The questioner here would apparently have made about seventy-five applications and, if he has carried out the proper instructions, will have used some pints of the medicament. The surprising factor is that some alleviation of scalp irritation is alleged, for it is more likely that this gross over-treatment would cause a dermatitis. If the treatment described has failed, no other treatment is likely to be more successful.

### Prostatitis

**Q.**—What is the treatment of non-specific prostatitis?

**A.**—The best treatment ought to be rectal diathermy followed by prostatic massage, but as active infection is present it should be supplemented by the use of one of the sulphonamides.

### Chronic Ulcer and Pemphigus

**Q.**—A man of 73 has had a chronic ulcer on the left great toe for two years. Culture produced a mixed growth of *Staph. aureus* and haemolytic streptococci and a heavy growth of coliform organisms. The ulcer was dressed with penicillin cream, and sulphathiazole tablets were given at the same time, but they appeared to cause an acute dermatitis of the foot. Allantoin-sulphanilamide preparations were also tried with the same result. The urine is negative for albumin and sugar. The patient has chronic rheumatoid arthritis, and chronic pemphigus vulgaris of the scalp and front of chest. Can you suggest treatment for this latter condition as well as for the toe ulcer?

**A.**—The patient should be seen by a dermatologist. If the diagnosis of pemphigus is confirmed there is no effective treatment and the ultimate prognosis is bad. It is presumed that x-rays have revealed no local cause for the ulcer of the toe. In the absence of organic nervous disease, it is possibly due to

vascular degeneration. Trauma or pressure is another likely causative factor, and resolution depends on treatment of the cause, which is almost certainly not infective. Cod-liver oil or 0.5% parachlorophenol in a bland base may be used locally.

### Titanium

**Q.**—May I have information regarding titanium for clinical use, or details of literature on the subject?

**A.**—Titanium dioxide is used in face powders and other toilet articles in place of zinc oxide. Titanium salts appear to diminish erythema and pruritus in certain dermatoses. There is on the market a proprietary desiccant paste for exudator dermatoses, containing titanium dioxide, zinc oxide, and small quantities of purified silicates in a fat-free base. Ointment containing titanium salts are also useful in irritation, dermatitis, localized eczema, sycosis barbae, pruritus after insect bites, erythema of solar dermatitis, and ulceration associated with varicose veins. They are said to be of some value in psoriasis.

## NOTES AND COMMENTS

**Pink Disease.**—Dr. W. G. BRANDER (Rochampton, S.W.) writes: With reference to the answer to the question on pink disease (Jun 21, p. 911), I was interested to see that no reference was made to the use of potassium chlorate and acid. hydrochlor. dil., as recommended by Peckham in the *South African Medical Journal*, 1941, 20, 474. This article was summarized in *Abstracts of World Medicine*, 1947, 1, 380. Peckham's treatment is not a direct answer to your correspondent, but might be of value to him in the treatment of his case.

**Ejaculatio Praecox.**—"V.B.G.-A." writes: Without labouring the point that the wise men came from the East, might I advise that the ejaculatio praecox patient referred to (June 28, p. 958) should follow the age-old Oriental practice of anointing the corona with a little 1% ung. cocain. just beforehand or, if preferred, with ung. opii. Either damps down the immediate reflex, and it will be found that after a few occasions it can be discontinued. I have prescribed this scores of times since I was told of it years ago by an ancient hakim in Calcutta and have never known it fail or give rise to any "habit."

## INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

### Commencement of Practice

M. E. has been demobilized and contemplates setting up in general practice. How should he deal with income tax demands for tax on his residence and income not taxed at source?

He is advised to get in touch with the local inspector of taxes, inform him as to the date as from which the practice is commenced, and undertake to supply a statement of account at the end of the first year of the practice. He should complete the usual form of claim to "married" and children allowance and ask that these allowances be set against the untaxed income, or alternatively that the tax assessed on that income should remain in abeyance until his first year's practice results are known. He will be entitled to deduct as professional expenses a reasonable proportion of the Schedule A assessment on the house, of the cost of running a car (including depreciation) and of such general expenses as cost of domestic service, telephone, etc. Cost of maintenance of drugs, instruments, medical library, etc., is permissible, but not the capital outlay of initial purchase or improvement of such assets. If the results of the practice working show a loss relief can be claimed against his own or his wife's taxed income.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attolsey* (Western), London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Drimedads*, Western, London. MEMBERS' (should be sent to the SECRETARY of the Association, London. B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 12 1947

## British Medical Association

### ANNUAL REPRESENTATIVE MEETING, 1947

The Annual Representative Meeting of the British Medical Association will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Tuesday, July 22, and succeeding days.

### RESOLUTIONS BY DIVISIONS AND BRANCHES

#### NATIONAL HEALTH SERVICE ACT

**Amendment by MARYLEBONE:** That the second half of the third paragraph of Section 20 is an inadequate and therefore misleading account of the events to which it refers.

(The part of para. 20 to which this amendment refers is—

"As a result of the plebiscite, a small majority of the profession expressed themselves against discussions on the regulations. The Special Representative Meeting on Jan. 28, 1947, on consideration of the plebiscite results, expressed its willingness that discussions should be entered into with the Minister, provided that such discussions were comprehensive in their scope and that the possibility that they might lead to further legislation was not excluded.")

**Amendment by MARYLEBONE:** That the following:

"90% of the entire profession took part in this plebiscite. The result of this was that 64% of general practitioners and 55% of the whole profession expressed themselves against discussions on regulations."

"Consequently, the Council drew up a resolution for the consideration of the S.R.M. on Jan. 28, 1947, to this effect. However, at subsequent emergency meeting the Council withdrew this resolution and substituted one which expressed willingness that discussions should be entered into with the Minister, provided that such discussions were comprehensive in their scope and that the possibility that they might lead to further legislation was not excluded."

"The reason for the change was the belief that the Minister of Health was showing signs of a more conciliatory attitude, as revealed in a letter addressed to the Presidents of the three Royal Colleges. The R.M. were informed of this belief and, in the hope that it was justified, they welcomed the possibility of conciliation and co-operation on the Minister's part so warmly that they passed the resolution by a large majority in spite of the plebiscite figures."

be substituted for the words referred to above.

#### Report of Negotiating Committee

**Motion by NEWCASTLE-UPON-TYNE:** That this meeting is of the opinion that the Negotiating Committee should be asked to make an early report of the progress and discussions with the Minister.

#### Meetings of Local Units

**Motion by BATH:** That in the event of the Negotiating Committee failing to secure the Minister's agreement to the declared principles, all Divisions of the Association should be asked to meet, in order to instruct their representatives before a special meeting of the Representative Body is held to discuss the terms of a plebiscite. Further, that the Council of the Association should then give a strong lead to the profession in the light of the findings of this Special Representative Meeting when issuing the plebiscite forms.

#### Plebiscite

**Motion by BUCKINGHAMSHIRE:** (1) That in the opinion of this meeting the result of a future plebiscite be binding on the Council. (2) That, prior to any future plebiscite, the clearest possible exposition of the Association's policy as to the issues involved be circulated by the Council. The actual voting paper should be sent to the voter under separate cover and unaccompanied by any expression of opinion.

#### Superannuation for Specialists

**Motion by DERBY:** That the Negotiating Committee be requested to examine the claims for superannuation for specialists retiring from hospital service on the inception of the National Health Service.

**Remuneration of Medical Officers Employed by Local Authorities**

**Motion by LOTHIAN:** That the Negotiating Committees in England and Scotland, in their negotiations with H.M. Government,

should endeavour to ensure that the rates of remuneration of all medical officers employed by local authorities should be uniform throughout Britain.

#### A Rota of Practitioners

**Motion by PADDINGTON:** That in any National Health Service adequate provision shall be made for a rota of practitioners for duty at night, week-ends, holidays, and during sickness.

#### Distribution of the Profession

**Motion by READING:** That, in view of the reason given by the Minister at the second reading of the Act for the abolition of the buying and selling of practices, as being necessary in order to correct maldistribution of practitioners, the Council formulate and publish a positive plan showing how this object could be achieved by other means

#### Health Centres

**Motion by SOUTHAMPTON:** That (1) in view of the fact that the medical profession may be concerned with the staffing of Health Centres to be set up in the National Health Service, it is important that a definite policy with regard to their construction, siting, and organization be adopted, and (2) the Representative Body instruct the Council to make definite plans regarding the construction, staffing and functions of Health Centres to be set up in the National Health Service.

#### Nominations for Statutory Bodies Under the Service

**Motion by NORTH STAFFORDSHIRE:** That this meeting demands that the profession's nominations to all statutory bodies under the new National Health Service be approved by the Minister of Health.

**Motion by TORQUAY:** (a) That the Negotiating Committee be instructed to press for a regulation that medical nominations to local Executive Councils be made at a General Meeting of practitioners in the area, serving under the Act. (b) That the majority of medical representatives on local Executive Councils should be in active general practice, whereas on the Regional Boards the majority should be consultants.

**Motion by MID-ESSEX:** To ensure satisfactory representation of the profession on any of the proposed administrative bodies set up by the Minister, he shall ask the medical practitioners concerned to nominate only as many freely elected representatives as there are vacancies.

#### Midwifery Services

**Motion by STRATFORD:** That the Representative Body take the following stand:

1. That all practitioners registered under the present Medical Acts shall be entitled to undertake domiciliary obstetrics under the National Health Service Act.

2. That ten years' experience in domiciliary obstetrics is an adequate preliminary condition of entry to an examination for a postgraduate diploma in obstetrics.

3. That, if the conditions governing examination for existing diplomas cannot be varied in this respect, an appropriate diploma should be newly established.

4. That the above recommendation should be conveyed to the Negotiating Committee.

#### GENERAL PRACTICE

#### Fees for Medical Examinations in connexion with Life Insurance

**Motion by the CHAIRMAN of the GENERAL PRACTICE COMMITTEE:** That the following recommendation of Council be adopted:

That Minutes 119-133 of the A.R.M., 1920, and Minute 81 of the A.R.M., 1935, regarding the fees payable for medical examinations in connexion with life insurance be rescinded and the following substituted therefor:

(1) That a "short" form of medical report be approved for use in the case of all insurances where the amount of the policy does not exceed £300, the fee for the completion of this form of report to be 10s. 6d.

(2) That for a medical examination and report in cases where the amount of the policy exceeds £300 the fee shall be £1 11s. 6d.

(3) That no attempt be made to standardize the £1 11s. 6d. form

of report, but that where the form required by the life office is exceptionally extensive a fee of £2 2s. should be payable.

(4) That where, in the case of an insurance for an amount not exceeding £300, the office requires a fuller examination than is provided in the "short" form, the office may use its ordinary form at a fee of £1 11s. 6d.

(5) That in all cases the fee appropriate to the examination, and the amount of the policy, should be printed on the form.

Amendment by BARNSTAPLE: That no report to insurance companies by a medical practitioner should receive a fee of less than £1 1s.

Amendment by NORTH STAFFORDSHIRE and WILLESDEN: That the Council be instructed to press for a fee of £2 2s. for medical examinations where the amount of a life insurance policy is £300 or over.

Amendment by TORQUAY: That the fee for the short form of medical report mentioned in sub-para. (1) should be £1 1s. If a more extensive form is required the fee should be £2 2s.

Amendment by WORCESTER AND BROMSGROVE: That in the opinion of this meeting, in cases where the policy amounts to £1,000 or over the fee shall be £2 2s.

Motion by MARYLEBONE: That the British Medical Association shall make a recommendation, after consultation with the Life Offices Association, on the question of the payment of fees when proposers fail to keep appointments with doctors.

#### *Fees for Police Calls and for Attendance on Members of Police Forces*

Amendment by TORQUAY: That in view of the discrepancy in the time between paras. 22 and 88 of Council's Report, the time has come when the hours constituting day and night visits should be standardized.

Amendment by TORQUAY, and KENSINGTON AND HAMMERSMITH: That the hours constituting a day visit should be 9 a.m. to 8 p.m. and the night visit 8 p.m. to 9 a.m.

#### *Fees for the Administration of Anaesthetics to Persons receiving Dental Treatment as an Additional Benefit under the National Health Insurance Acts*

Motion by the CHAIRMAN OF THE GENERAL PRACTICE COMMITTEE: That the following recommendation of Council be adopted:

That where practitioners are requested to administer anaesthetics to insured persons receiving dental treatment as an additional benefit under the National Health Insurance Acts, the following fees should be paid:

*For the simple administration of nitrous oxide or similar anaesthetic:*

Fee per administration, for the extraction of:

1-5 teeth	.. .. .	10s. 6d.
6-10 teeth	.. .. .	£1 1s. 0d.
11-20 teeth	.. .. .	£1 11s. 6d.
21 or more teeth	.. .. .	£2 2s. 0d.

always provided that an increased fee shall be payable in specially difficult circumstances.

Amendment by CARDIFF: That the recommendation be referred back for further consideration, with a view to the introduction of a flat rate.

#### *Fees for Medical Certificates under the Lunacy and Mental Deficiency Acts, and for Recommendations under the Mental Treatment Act*

Motion by the CHAIRMAN OF THE GENERAL PRACTICE COMMITTEE: That the following recommendation of Council be adopted:

(i) That the existing policy of the Association relating to the fees for medical certificates under the Lunacy and Mental Deficiency Acts, and for recommendations under the Mental Treatment Act, be resumed:

(ii) That there be substituted therefor the following:

(1) *Fees for Medical Certificates under the Lunacy Acts:* A fee of at least two guineas should be paid.

(2) *Fees for Medical Certificates under Mental Deficiency Act:* The fee for medical certificates under the Mental Deficiency Act, signed by the "usual medical attendant," should not be less than two guineas.

(3) *Fees for Recommendations under Mental Treatment Act:* In cases where a "recommendation" is made under the Mental Treatment Act for a private patient the fee should be a matter of arrangement between the relatives and the practitioner concerned, but in public assistance cases a fee of not less than two guineas would appear to be appropriate.

Amendment by DERBY: Fees for medical certificates under the Lunacy Acts—a fee of at least two guineas should be paid (1) whether the certificate is completed or not, (2) whether the certificate is completed and the patient is discharged by the Justice.

#### *"Doctor" Signs on Cars*

Motion by KENSINGTON AND HAMMERSMITH: That with reference to para. 28 of Annual Report of Council further action be taken with a view to securing the removal of all "doctor" signs from cars.

#### *Supplementary Clothing and Other Coupons*

Motion by SWANSEA: That, with reference to para. 37 of Council's Report, appropriate action be taken to secure a freer use of gowns in view of the fact that when coupons are presented it found that they cannot be honoured. The same applies with regard to rubber gloves.

#### *Fees for Mileage and Visits for Local Authorities and Government Departments*

Motion by BARNSTAPLE: That fees paid by public authorities including Government Departments, for mileage and visits should be standardized.

#### *Public Medical Service: National Deposit Friendly Society*

Motion by DARTFORD: That the present rates of payment under the Public Medical Service and the National Deposit Friendly Society be reconsidered in view of increased cost of drugs, etc., so as to compare with the higher fees now paid for other medical services of a like nature.

#### *Reports to Coroners*

Motion by DERBY: That when a practitioner is requested by a coroner to furnish him with a medical report in respect of a deceased person for whom a death certificate cannot be supplied in the usual manner, the coroner shall pay the practitioner a fee of one guinea for such a report.

Motion by ROCHDALE: That steps be taken by the Association to secure payment on a uniform scale for medical reports to coroners in all cases.

#### *The Scope of General Practice*

Motion by LEEDS: That the Council be instructed to resist to the utmost any attempt to diminish the present scope of general practice.

#### *Doctors' Cars*

Motion by GREENWICH AND DEPTFORD: That this meeting is dissatisfied with the present arrangements made by the Association for obtaining doctors' cars, and urges the Council to take appropriate action to secure definite priority.

#### *Doctors' Evening Surgeries*

Motion by SHEFFIELD: That this Representative Meeting consider that the time has now arrived when it is no longer in the public interest that doctors' evening surgeries should continue to the present late hour. There should be an immediate review of times of surgery hours.

#### *Certification*

Motion by ABERDEEN AND KINCARDINE COUNTIES: That at this meeting, while appreciating the need for certification during the present world shortages, deplores the increasing number of certificates which doctors are asked to give, and recommends that in future all demands for further certification should be submitted to a sub-committee of the General Practice Committee and passed reasonable before the profession is asked for these certificates.

#### *NATIONAL HEALTH INSURANCE*

##### *Medical Records of Demobilized Persons*

Motion by WORCESTER AND BROMSGROVE: That with reference to para. 53 the Council be asked to investigate the legal position as to the use of these medical records for any purpose which is for the benefit of the patients, including pensions appeals.

#### *Certification*

Motion by PADDINGTON: That, with reference to para. 55 of Council's Report, certification shall only appertain to the witnessing of a signature and not vouch for the accuracy of the material contents of the said certificate.

#### *SPECIAL PRACTICE*

##### *Rules for the Government of Groups and Consultants' and Part-time Consultants' Rolls*

Amendment by WORCESTER AND BROMSGROVE: That, with reference to para. 62 of Council's Report, this meeting, being desirous that the views of part-time consultants and specialists should receive adequate consideration, is of the opinion that membership of Consultant and Specialist Groups should be open to members of the part-time Consultants and Specialists Roll.

*Salaries of E.M.S. Specialists*

Amendment by WORCESTER AND BROMSGROVE: That, while approving para. 68 of Council's Report as a step in the right direction, this meeting is of the opinion that the increases allowed are insufficient and should be accepted only on the understanding that such acceptance is without prejudice to scales of remuneration in any future health service.

*Access to Ancillary Departments of Hospitals*

Amendment by GREENWICH AND DEPTFORD: That, with reference to para. 71 of Council's Report, this meeting regrets the obscurity of Council's recommendation and feels that until ancillary departments are adequately staffed the "open door" policy is fraught with danger.

**HOSPITALS***Shortage of Nurses*

Motion by KENSINGTON AND HAMMERSMITH: That Council should ask the Minister of Health to give urgent attention to the solution of the problem created by the grave shortage of nurses, since it is affecting the health of the nation.

*Remuneration of Practitioners holding Junior Hospital Posts*

Motion by PLYMOUTH: That the present remuneration for junior hospital posts is entirely inadequate and the British Medical Association should formulate a scale of salaries for adoption by all hospitals.

**PUBLIC HEALTH***Practitioners Employed Part-time by Local Authorities*

Amendment by EAST YORKSHIRE: That the Annual Representative Meeting, 1946, having approved the recommendations of Council relating to a minimum scale of fees appropriate to part-time medical work on a sessional basis, this meeting views with dismay the action of Council in propounding a lower scale of fees to which its negotiations with other bodies would appear to have committed the profession, repudiates such action as prejudicial to the present and future interests of the profession, as well as a betrayal of the mandate sought by the Council and accorded at its request, and reaffirms resolution 100 of A.R.M., 1946.

Amendment by NEWCASTLE-UPON-TYNE: (1) That the mileage fee for consultants agreed at the A.R.M., 1946, is inadequate and should be increased. (2) That a consultant called to an emergency case for consultation followed by operation should receive a consultation fee in addition to the mileage and operation fees.

*Trade Union Membership*

Motion by GATESHEAD: That the attention of the Minister of Health be drawn to the flouting of his recommendation as to the non-enforcement of the "closed shop" principle, as applied to doctors, by various local authorities in the country.

*Salaries in Public Health Service*

Amendment by NORTH STAFFORDSHIRE: That the Council be instructed to reconsider the minimum salaries for whole-time consultant and other appointments.

Motion by CARDIFF: That, with reference to para. 80 of Annual Report, when the revision of the Askwith scale of salaries in the Public Health Service takes place the new scale should be retrospective from April 1, 1946.

Motion by GATESHEAD: That the inadequacy of the present salary award to whole-time Public Health Medical Officers be emphasized and that care should be taken in future negotiations that any salary scale for whole-time officers be considered in relation to increases in fees payable for part-time Public Health and Hospital work.

*Milk*

Motion by HARROW: That, with reference to para. 84 of Council's Report, this meeting considers that the breadth of the problem demands consideration by an Inter-Departmental Committee of the Government, including the Ministries of Food, Agriculture, Health, and any other Department concerned with the production and distribution of milk; and requests Council to press the Government for the appointment of such a Committee.

Motion by MARYLEBONE: That this meeting wishes to impress upon the Minister of Health the urgent necessity of action by the combined efforts of the Ministers of Health, Food, and Agriculture in order to ensure that clean safe milk is made available as efficiently as possible.

**FINANCE***Subscription to the Association*

Amendment by GREENWICH AND DEPTFORD: That this meeting is of the opinion that the time has now arrived when an increase in present subscription rates should be considered.

**MEDICAL ETHICS***Rules of the Central Ethical Committee relating to Complaints regarding Professional Conduct*

Amendment by NEWCASTLE-UPON-TYNE: That this meeting agrees to the expulsion of a member who has accepted an appointment subject to an important notice in the *Journal*, but that all other cases of ethical conduct should originate in the Branch or Division.

**ORGANIZATION***Expenses of Members attending Meetings*

Motion by GREENWICH AND DEPTFORD: That this meeting approves the principle of payment of expenses of members attending meetings, but considers that the rates suggested by the Organization Committee are inadequate and would still debar the younger member accepting office, and recommends that they be doubled.

[Note: The rates suggested by the Organization Committee were as follows: That, in addition to first-class return railway fares (including sleepers), payment of subsistence allowances be made to members of the Association attending centrally arranged meetings on the following basis:

For absence from home over 8 hours .. .. .	10s. 0d.
Where stay overnight is necessary an additional .. .. .	£1 0s. 0d.
Where a sleeper is claimed the overnight payment to be reduced to .. .. .	10s. 0d.

Where attendance on consecutive days does not necessitate the use of hotel accommodation payment on the day basis only to be made.)

Motion by GATESHEAD: That, with reference to para. 96 of the Annual Report of Council, payment of representatives attending central meetings should be on a factual basis of actual submitted expenses up to a predetermined maximum.

Motion by LEEDS: (1) That Representatives, Members of Council and members of Standing Committees or other Committees or meetings for the conduct of business of the Association arranged centrally be paid out of the general funds of the Association subsistence allowance at a rate to be determined by the Representative Body from time to time.

(2) That By-law 86 be amended to read as follows:

The expenses of any person which in pursuance of the 49th Article of Association are to be defrayed out of the general funds of the Association are the first-class travelling expenses (including where necessary the cost of a sleeping berth) within Great Britain and Northern Ireland of that person together with such allowance for subsistence as may be determined by the Representative Body from time to time.

(3) That the subsistence allowance payable to members under By-law 86 shall be as follows:

1. For each day on which the member shall be engaged away from his practice for not less than 8 hours between 8 a.m. and 8 p.m. .. .. .	10s. 0d.
For each night spent in travelling .. .. .	10s. 0d.
For each night where it is necessary to stop in a hotel .. .. .	£1 0s. 0d.

**GENERAL MEDICAL COUNCIL***Election of a Woman Practitioner as a Direct Representative of the Profession on the General Medical Council*

Amendment by PLYMOUTH: That the existing procedure is adequate to ensure that a woman can be elected to the G.M.C. on her merits.

**PUBLIC RELATIONS***Information Service at B.M.A. House*

Motion by BATH: That the Public Relations Committee of the Association be urged to encourage its activities in giving to the public authoritative information on hygiene and medical progress such as is obviously popular when supplied by other agencies.

**EXECUTIVE COUNCILS IN SCOTLAND**

The Secretary of State for Scotland has fixed the areas that the 25 Executive Councils will administer under the National Health Service (Scotland) Act. Glasgow, Edinburgh, Dundee, and Aberdeen will each have an Executive Council, as will the counties of Angus, Ayr, Caithness, Dumfries, Dunbarton, Fife, Inverness, Lanark, Orkney, Renfrew, Ross and Cromarty, Sutherland, and Zetland. An Executive Council will be appointed to each group of counties as follows: Aberdeen and Kincardine; Argyll and Bute; Banff, Moray, and Nairn; Kirkcudbright and Wigtown; Midlothian, West Lothian, East Lothian, and Peebles; Perth and Kinross; Roxburgh, Berwick, and Selkirk; Stirling and Clackmannan. The members of the Councils are expected to be appointed in a few weeks' time.

## MEDICAL ORGANIZATION IN DENMARK

### THE STATE SERUM INSTITUTE

BY

PETER KRAG

*Head of Department, State Serum Institute, Copenhagen*

The State Serum Institute was established in 1902. The main object was the production of diphtheria antitoxin serum, but it was intended to take up similar work on other diseases according to the possibilities arising. Since then its development has been stamped by the Institute's being the sole central laboratory for diagnostic bacteriology and serology in the country. Besides considerable extension of the diagnostic work the Institute comprises larger and smaller factory-like plants for the production of sera and vaccines, and in connexion with these much scientific work is carried on—applied science as well as pure research.

The diagnostic work is arranged in several departments. A department for general bacteriology carries out all diagnostic bacteriology, including Widal and Bunnell tests; the tuberculosis and pneumococcus diagnoses are undertaken in separate departments, where also the production of tuberculin and anti-pneumococcal sera is carried out; a serodiagnostic department is responsible for the serological diagnosis of syphilis and gonorrhoea. Further, there are a special department for blood typing and dried serum production, and a hormone department (9,000 tests for pregnancy in 1945). Production proper is managed by the serum department (diphtheria antitoxin and vaccine; convalescent sera), the anaerobic department (other sera), and the vaccines department (smallpox vaccine and bacterial vaccines). The Calmette vaccine is produced in the tuberculosis department (40,000 persons vaccinated during 1945). In connexion with serum production a physico-chemical department performs concentration of the sera. All the finished products pass through a control department. Two special departments take care of the international work carried out at the Institute, namely, the department for standardization of sera and toxins, and the Salmonella Centre. There is a considerable plant for the production of foot-and-mouth disease vaccine. Virus research, which is going on in two or three departments, has not yet a department of its own.

Common to these special branches are the administration, scientific library, stables and farming, and departments for culture medium preparation, cleaning, workshops, supplies, etc.

#### Diagnostic Service

Any doctor and any hospital have the right to send samples to the Institute for diagnostic purposes, and they may requisition packing and blank forms free of charge. All tests of importance for the control of epidemic disease are carried out gratis, while prices for other tests have been fixed in accordance with the actual expenditure of the department in question, given in a quarterly note of account. Payment follows from the hospitals direct (i.e., from the commune or county in question). Doctors are liable for tests carried out in connexion with private practice, but have a right to charge the cost with their fee. In panel practice the doctor simply fills in the name of the panel on the form, and the panel gets a quarterly note of account covering the investigations requisitioned by a number of panel doctors.

Every doctor in the country gets an annual survey (in the Organization's *Pocket Book*) of the diagnostic facilities offered, together with a list of prices. Applications for free investigations may be met in the case of research work or if the patient is poor.

Samples are received throughout the twenty-four hours. Serological investigations are started at 10 a.m. (Widal tests repeatedly during the day); bacteriological examinations are taken from 9 a.m. to 11 p.m.; particularly important samples are dealt with during night hours also. The results are sent by mail; but telephone and telegraph are used in accordance with doctors' wishes and whenever it is deemed necessary by a positive finding of, for instance, typhoid bacilli. With each

answer, on the back of the form, an explanation of the results obtained is given, and the diagnostic consequence likely to ensue is suggested.

As the size of the country in relation to the railroad system makes it possible for samples to reach the Institute within six to eighteen hours, the whole area of Denmark is covered, even the remotest corners of Jutland. It is true, however, that doctors in some parts of the country have to take a sample from their patients (e.g., for gonococcus culture) just before the train leaves.

The departures from the system of centralized diagnosis are few and may in part be looked upon as virtual outposts of the Institute: (1) Many doctors do their own microscopy with regard to gonorrhoea and tuberculosis. (2) Most clinical laboratories (in the hospitals) manage the diagnosis of *Bact. coli*, staphylococci, etc., in cultures from urine and pus, and the microscopical diagnosis of gonorrhoea and tuberculosis. (3) Most hospitals diagnose diphtheria by the culture method. (4) The Institute has for some years run eight auxiliary laboratories for pneumococcus typing, and one for gonococcus diagnosis by culture. These provisional laboratories are being developed at present.

As the culture methods are vastly superior to microscopy for gonococci and tubercle bacilli, there is an increasing demand that samples should go direct to the Institute in order to secure the best possible basis for diagnosis and control. As for diphtheria, the Institute is the only place where type and virulence can be ascertained.

#### Material for Education and Records

Material from the Institute is utilized by the university in the training of medical students, and its routine methods are taught. It is a rule that alterations occurring in the diagnostic methods are described and accounted for in the Organization's weekly *Ugeskrift for Læger* (corresponding to the *B.M.J.*). A post-graduate course is usually held at the Institute annually. It is attended chiefly by a few doctors wanting to specialize in research work or who require an addition to the hospital training.

As the Danish population is rather small, about four million, a survey is manageable, and the Institute is able to run a series of indexes, comprising, for instance, all typhoid and paratyphoid carriers, all tuberculous patients, all syphilitics, all patients with a positive gonococcus complement-fixation reaction or positive gonococcus culture, and all members of authorized blood donor corps. These indexes are kept up to date from the results registered in the various departments and by means of compulsory notification from practitioners and from hospitals, sent through medical officers. The indexes give information to any doctor inquiring into the case history of a patient, and in return are provided with the information necessary for registration and classification. The Institute receives ten to forty inquiries daily by letter or telephone from doctors wanting advice on diagnosis and therapeutics—which tests should be used in a certain case, how a result should be interpreted, or what is the correct use of the Institute's sera and vaccines. Some of the questions, however, are referred to specialists among the chief physicians or professors in the capital.

Sera and vaccines are distributed to hospitals, clinics, and doctors upon written or telephoned requisition at any time of the day or night. Payment follows the rules for diagnostic investigations mentioned above. Since the panel institutions refuse on principle to pay for any prophylactic measure—some of the vaccines form exceptions to the rule—the patients have to pay themselves. Diphtheria vaccine, however, is free of charge; and, as for vaccination itself, a law was passed a few years ago fixing doctors' fees and stating what public institutions are liable for payment.

#### Income and Expenditure

The size of the Institute appears from the following figures for 1945-6.—Employees: laboratory, 249; administration, stables, cleaning, workshops, etc., 379. Income: about £150,000; expenditure: about £300,000. The annual deficit is

met by Parliamentary vote; the cost of new plants and buildings is covered by special grant.

The number of samples received per year approaches one million, divided into groups as follows: bacteriology, 300,000; serology, 500,000; others, 100,000.

### Public Health and Research

A central institute is an immensely valuable organization, when the size of the population is less than five to six million and proper means of communication are at hand. It means that all diagnoses become comparable. It is easy to maintain a high technical standard, since the use of controls necessitates only a proportionately small amount of work. The doctors and hospitals can send the day's diagnostic material in one package. The Institute receives a large and uniform quantity of material suitable for the evaluation of practical routine work as well as for research. It is also possible for the staff to survey diagnostic and epidemiological problems of the whole country; and therefore the State epidemiologist, who is called for as adviser to the medical officers whenever an epidemic shows signs of becoming serious, has his daily activities divided between the Board of Health and the Institute.

The following are minor disadvantages of the centralized work: the large scale on which the work has to be done is accomplished only by means of a somewhat factory-like organization, and a certain skeleton-like treatment of the individual sample may ensue; unfortunately, also, the subordinate laboratory personnel have a very monotonous and unqualified task. The staff may find it difficult to keep abreast of the scientifically important material accumulating.

Research work is considerably furthered by the possibilities for team work naturally afforded by a branched and full-grown central institute providing efficient and highly qualified technical assistants in many fields. Problems of room and personnel may here be more easily settled since not all departments are fully loaded at the same time. But, on the other hand, if planning for extensions and new buildings is neglected the resulting disadvantage is considerably more serious than in the case of minor laboratories, where the difficulties may perhaps be overcome by the addition of an extra room or two. Further, an independent, central institute with a monopoly may lead to stagnation, since criticism and new ideas are seldom brought forward or perhaps dismissed as not well founded. A fruitful scientific reciprocal relation can be established only with similar institutes in foreign countries.

The leading posts of the Institute are filled by physicians and pharmacists who are permanent functionaries; all have to regard the Institute situation as full-time employment not allowing any paid extra job. This means that at the age of 40-45 they have become specialists within a narrowly limited field and have very little opportunity indeed for obtaining favourable conditions elsewhere. This feeling of dependency is to some extent compensated by the excellent access to scientific work offered by the Institute—in theory. In practice, long periods of necessary routine work together with want of space may tend to diminish the possibilities for research work. To our young medical assistants an appointment of from two to four years means a valuable scientific scholarship, since the routine work they are called upon to carry out can be accomplished within three or four hours of the day, while culture media, chemicals, animals, etc., are placed at their free disposal—granted of course that the principals approve of the research plan in question.

### Freedom from Financial Profit

In my opinion it is an essential advantage that the Institute is not a private enterprise with a demand for a certain annual balance, since this might lead to a price policy obstructing many useful investigations of importance to the patients as well as to science. If the standard of scientific work in a country's sole central institute can be maintained equal to that of other countries, and if the institute's daily experience is utilized in the right way, the central institute constitutes the most economical and manageable solution to the practical and scientific problems connected with bacteriology and serology.

### RELEASE FROM THE FORCES

The following is the latest information received by the Central Medical War Committee on the arrangements for the release of medical officers in Class A.

**Royal Navy.**—July 1-Aug. 31: Group 62; Sept. 1-30: Group 63.

**Army.**—General Duty Officers: July 1-Aug. 15: Group 60; Aug. 16-Sept. 30: Group 61. Specialists: July 1-31: Group 51; Aug. 1-31: Group 52; Sept. 1-30: Group 53.

**Royal Air Force.**—July 1-31: Group 60; Aug. 1-31: Group 61; Sept. 1-30: Group 62.

### HEARD AT HEADQUARTERS

#### Self-certified

In the strange retort houses of the Ministry of Fuel and Power the ancient taunt, "Physician, heal thyself," becomes not a taunt but an injunction, "Physician, certify thyself." A correspondent raised with the Ministry the question of space heating in doctors' surgeries and asked about the necessary authority for such heating. He received in due course a reply from the Parliamentary Secretary stating that it was assumed that the reference was to a room in the doctor's own house which he used as a surgery. "If this is the case the use of gas or electricity, where necessary in the interests of his patients' health, can be covered by a certificate issued by himself." Then there followed the usual reminder of the need for economy. The certificate, presumably, will be something to this effect: "I, John Brown, certify that I, John Brown, am entitled to use a gas fire in my surgery." To whom is this certificate to go? Who is to "vet" it? What penalties are to be imposed if it is "untrue, misleading, or improper"? If a doctor who is himself neither a septuagenarian nor an infant (the certificate of course should be specific on that point) switches on his electric radiator, does the filling up of a certificate by himself legalize an illegal act? Where is the line to be drawn? May a doctor, on the ground that his own well-being is necessary to the health of his patients, certify himself as eligible for extra rations? This is surely another instance of the faith in form-filling which has descended on official bodies. Everything is all right if it is vouched for on the dotted line.

#### No Parking

The no-parking rule in certain streets in West and Central London has its advantages in speeding up traffic, but it can be very inconvenient to a doctor if he is required to park his car a considerable distance away from the premises to which he has been called. Fortunately the streets affected by the new order are mostly non-residential; nevertheless, doctors are called in emergencies to business premises. The Association has asked the Commissioner of Metropolitan Police whether a practitioner who is called to a sudden emergency may be allowed to park his car in the prohibited area. An ambulance is permitted to stop in a no-parking street, and the doctor on an emergency call is on no less important an errand.

#### Scotland under Dissection

The Registrar-General for Scotland described to the Royal Statistical Society the other day the projected third Statistical Account of Scotland, which is being undertaken through the generosity of the Nuffield Foundation. The first Statistical Account was completed at the beginning of the nineteenth century, and the second in 1845. It is much more than a census: it is a collection of information on the way of life of each local community, the attitude of the people to work and leisure, the changes in public and social services, and it includes local customs and traditions, local ballads and sayings, and even medicinal cures or food recipes which are peculiar to the parish under review. Four preliminary surveys are already being undertaken, each under the special supervision of one of the Scottish

universities—namely, in the counties of Ayr, East Lothian, and Fife, and the city of Aberdeen. For this purpose the goodwill of many national and local bodies in Scotland has been secured, among them the Scottish Council of Social Services, the Convention of the Royal Burghs, the Association of County Burghs, educational institutes, and the presbyteries. Clergymen of every church, teachers of every school have been asked to co-operate. It was curious that not a word was said by the Registrar-General about the help which medical practitioners and medical officers of health could give in such a survey. Very possibly such help has been enlisted, but it was not mentioned. The doctor knows the lives of people behind doors which may be closed to ministers of religion. No one has a better knowledge of the domestic background to the social scene.

## Correspondence

### Buying of Practices

SIR,—In answer to my letter published in the *Supplement* of June 7 (p. 116) Dr. J. Michael Jones states (*Supplement*, June 21, p. 153) that I repeat the glib statement that up to 100% of the price of a practice may be obtained at low rate of interest; he had heard this stated so frequently, usually by old practitioners, etc. I must refute his statement, which I am in a position to do authoritatively, having recently availed myself of one of the schemes available. The bank did not require a guarantor. All the bank required was a life assurance policy to cover the amount of the loan, which policy had no surrender value, having been recently taken out, an assurance of personal integrity, and a copy of the audited accounts of the practice over the past six years. The bank take a charge on the goodwill of the practice and an assignment of the life policy; repayment is over ten years usually, but may in a few cases be extended to fifteen.

When one considers that a building society will usually loan 90% of the cost of a house over 20 years, it will be seen that very little capital is actually necessary for the purchase of a house and practice, and not many years of assistantship would be necessary to acquire these means.

It seems possible to me that the Treasury hope to make more than the 4% p.a. on medical practices after they have "taken over."—I am, etc.,

Prestatyn, Wales.

T. H. HARGREAVES.

SIR,—With reference to Dr. J. Michael Jones's letter (*Supplement*, June 21, p. 153) concerning the buying of practices, I would point out that last year I borrowed 100% of the amount to buy my practice without security save for £300 of saving certificates. The latter I need not have given, but I preferred to do so. The loan was arranged by a firm that advertises in the *Journal*, and my bank advanced the money. The same bank allowed an overdraft of £300, to run if necessary for five years. The loan is to be repaid in 15 years, interest being 4% per annum.

I have since borrowed a further substantial sum to buy another share in a practice, and this was arranged in five minutes over the telephone. References are of course required, but the only one I gave was from my former Army A.D.M.S. The only other condition is that a life insurance equivalent to the amount borrowed has to be held by the borrower. I should perhaps add that other firms are less obliging.—I am, etc.,

Newport Pagnell, Bucks.

A. A. CLAY.

### Extension of N.H.I.

SIR,—Dr. A. Crawford Mayer (*Supplement*, June 21, p. 153) comments on the N.H.I. Service. His suggestions, and others, are to be found in "The B.M.A.'s Proposals for a General Medical Service for the Nation" (1930). I would like to know why the B.M.A.'s admirable plan has attracted so little attention.—I am, etc.,

Chichester, Sussex.

G. T. RUTHERFOORD.

## Association Notices

### PROPOSED WEST WIGTOWNSHIRE DIVISION

Notice is hereby given by the Council of the Association that it is proposed to form a separate Division composed of the members of the Association in West Wigtownshire (at present included in the Dumfries and Galloway Division and forming part of the Border Counties Branch), and to attach this new Division to the Glasgow and West of Scotland Branch, the area of the Division being defined as follows: Wigtownshire with the exception of the parishes of Glasserton, Whithorn, Sorbie, Kirkcinner, Wigtown, and Penninghame. The area of the Dumfries and Galloway Division to be consequentially amended.

Any member affected by the proposal and objecting thereto is requested to write to the Secretary by Aug. 12 stating the objection and grounds therefor.

CHARLES HILL,  
Secretary.

### Diary of Central Meetings

JULY

- 22. Tues. Council, 11 a.m.  
Annual Representative Meeting, 2 p.m.
- 23. Wed. Annual Representative Meeting, 10 a.m.  
Annual General Meeting, 12.30 p.m.
- 24. Thurs. Annual Representative Meeting, 10 a.m.

### Branch and Division Meetings to be Held

EAST YORKSHIRE BRANCH.—At Quern House, Park Street, Hull Tuesday, July 15, 8 p.m. Discussion of agenda of Annual Representative Meeting and instruction of Representatives. Saturday, July 26, 3 p.m. Visit to "The Retreat," Haslington Road, York.

ISLE OF WIGHT DIVISION.—At Royal Isle of Wight County Hospital Nurses' Home, Adelaide Place, Ryde, Monday, July 14, 8.15 p.m. Dr. L. A. Hulst (Dean of University Hospital, Utrecht) "Experiences of Medicine in the Occupied Netherlands."

WESTMINSTER AND HOLBORN DIVISION.—At City Hall, Charing Cross Road, W.C., Thursday, July 17, 8 p.m. Agenda: Consideration of Supplementary Report of Council for 1946. To formulate amendments to published motions on agenda for A.R.M.

### Meetings of Branches and Divisions

#### EDINBURGH AND SOUTH-EAST OF SCOTLAND BRANCH

Dr. P. Martin Brodie, retiring President of the Branch, and Mr. Brodie received a large gathering of members and their friends at the Hall of the Royal College of Surgeons, Edinburgh, for the Annual Summer Meeting of the Branch on June 25. In welcoming the guests Dr. Brodie expressed to the President and Council of the Royal College the sincere appreciation of the Branch for the great privilege of being allowed to hold their meeting in the honourable precincts of the College. In replying, Mr. J. M. Graham, President of the Royal College of Surgeons of Edinburgh, hoped that this might be the first of many future occasions when members of the British Medical Association would be welcome guests.

Dr. Douglas Guthrie, Honorary Librarian, gave an entertaining account of the history and traditions of the ancient College from its foundation in 1505 to modern times. The social activities culminated in a sumptuous tea with strawberries and cream. After the reception the Annual Meeting of the Branch was held, the main business being the election of office bearers, with Dr. G. W. Ireland as the new President.

#### SOUTH-WESTERN BRANCH

The 107th Annual Meeting of the South-western Branch was held at Torquay on June 12, when Dr. F. D. M. Hocking, of Truro, resigned the chair to Dr. P. A. McCallum, of Torquay. Dr. McCallum gave his inaugural address on "The Practice of Medicine in Retrospect and Prospect." He said that they stood to-day at the close, or very near the close, of an era in medical history. They saw themselves threatened with governmental control becoming the servants of the State rather than the servants of their patients.

At this critical phase in the history of medicine what could they do to be saved? First, they must at all costs retain and safeguard their individual freedom to deal with their patients as they believe to be best. There must be freedom of judgment, action, speech, and publication. Secondly, if they were to retain their freedom probably one of their greatest needs was unity. The diversity of activities and interests within the profession made that difficult. They needed more opportunities for friendly intercourse and for discussion of their general and individual problems. Thirdly, they must preserve a due sense of proportion, uninfluenced by personal idiosyncrasies, personal likes and dislikes. And fourthly, their public relations must be developed and improved.

LONDON SATURDAY JULY 19 1947

## SOME ASPECTS OF HUMAN INFERTILITY

BY

ALBERT SHARMAN, M.D., Ph.D., B.Sc., M.R.C.O.G.

Senior Assistant Surgeon, Royal Samaritan Hospital for Women, Glasgow

Although infertility is one of the oldest of human problems it is only within the present century that real progress has been made in its study. But in these comparatively few years intensive work has been done on this subject, and the accumulated literature is now enormous. It is not my intention to refer to more than the essential relevant writings or to give an exhaustive account of the complete investigation and treatment of a barren marriage. It is proposed, rather, as indicated in the title of the paper, to discuss certain selected aspects of the subject which have been under personal study and investigation during recent years—namely: (1) The tubal status—patency and non-patency—as determined by insufflation in a consecutive and unselected series of 1,478 cases of primary sterility. (2) Therapeutic aspects of insufflation, based on 271 cases of pregnancy following insufflation in primary sterility. (3) Tuberculous endometritis and primary sterility—a study of 100 cases (the largest series ever recorded). (4) The causation of tubal occlusion.

## The Tubal Status

Patency of the lumen of the Fallopian tube is an obvious essential to conception. But the tube is not a static entity: not only does its muscular coat undergo peristaltic movements but its fibres increase and decrease in length with the phases of the cycle. Guthmann (1922) was the first to record the fact that tubal peristalsis was responsible for the manometric fluctuations on insufflation, and he based his conclusions on the fact that when the tubes were closed these fluctuations were absent. Müller (1944) has shown by hysterosalpingograms that peristalsis occurs in the tubes, both in the direction of the uterus and from the uterine end towards the fimbriae. In two cases of sactosalpinx he demonstrated that iodine masses moved from place to place as the result of peristalsis and antiperistalsis. Peristalsis has been observed by Westman (1930) in the monkey and by Mikulicz-Radecki and Nahmmacher (1926) and by Siegler (1944) in the rabbit. Peristaltic movements or contractions in the human tube had never been directly visualized until August, 1946, when I observed them during the course of an operation for the removal of a diseased ovary. I had been utilizing the opportunity for studying the effects of insufflation (per vaginam) on the tubes when their fimbriated ends were clamped. As soon as the pressure forceps were released peristaltic movements in the direction of the fimbriated ends were clearly seen and demonstrated to the assistant, house-surgeon, and anaesthetist. These movements were seen in only one of nine such experiments. As Ruddick (quoted by Siegler, 1944) has failed to notice any tubal peristalsis on peritoneoscopy in over 2,000 cases,

it is probable that the non-physiological conditions imposed by experiment were responsible for inducing peristalsis in my case.

Since the functional condition of the tube to a large extent determines the chances of fertilization it is obviously *desirable to investigate this aspect of the reproductive mechanism*. Although the available methods are not physiological they have the advantage of being easy to apply and of yielding sufficiently accurate information for clinical purposes. They should be adopted as part of the routine examination of the wife, for impairment of tubal function cannot be excluded by the ordinary bimanual examination, however carefully conducted.

The methods in general use fall into two main groups—those designed to investigate the passage of a gas through the genital tract (utero-tube insufflation) and those in which the condition of the tubes is revealed by their radiographic appearances after the injection of a suitable opaque substance (hysterosalpingography). It is proposed here to discuss only insufflation, for which purpose various types of apparatus have been described since the introduction of the method by Rubin in 1919. The outstanding advance in recent years has been the inclusion of the kymograph, which makes possible the registration of tubal contractions and thus takes into consideration the actual behaviour of the tubes during the test. Four types of record are obtained, corresponding to the following conditions: normal tubal patency, tubal spasm, tubal stenosis, and non-patency.

The total number of patients in the series whose tubes were insufflated amounted to 1,478, of whom about 400 had two or more insufflations. In most instances the test was repeated simply as a confirmatory procedure; in some it was done to compare the findings with and without anaesthesia; but in 22 patients six or more tests were done to study the behaviour of patent tubes over a considerable period of time. One patient was insufflated 23 times over a period of seven months and another daily for the 18 days between the conclusion of one period and the beginning of another.

A study of the behaviour of patent tubes as revealed by repeated insufflations shows that under similar conditions—for example, the consistency of the rate of flow of the gas—there is a noteworthy constancy in the appearance of the tracings obtained. No great difference, either in the level at which patency is established or in the appearance of the tubal contraction waves, is usually seen in any given patient when insufflation is repeated even after several months. Increase in the rate of flow of gas is sometimes followed by a great increase in the patency-pressure level and by more active deeper peristaltic waves, but this is not invariable. Around ovulation time (presumptive) more active or more frequent peristalsis may occur. This also

\*Being the substance of a paper read, by invitation, at the South African Medical Congress, Durban, October, 1946.

is variable, and there is no indication of any constant close correspondence between the type of tracing obtained and the stage of the endometrial cycle. On the other hand, repeated insufflations have shed some interesting light on the criteria of non-patency. The first point is that a single finding of non-patency is not reliable. This has been proved by the subsequent occurrence of a characteristic kymographic tracing of patency (corroborated by the presence of shoulder pain or by the demonstration of pneumoperitoneum), or by hysterosalpingography, or by the occurrence of pregnancy. In a consecutive series of 57 patients in whom the tubes were not permeable to gas on insufflation under anaesthesia, repetition of the test a few days later, without anaesthesia, showed normal patency in 39 (68.4%). This would indicate that only 31.6% of these cases showing non-patency on a single test actually have occluded tubes.

Insufflation has revealed apparent non-patency in 387 (26.2%) of the 1,478 cases. In the earlier cases the diagnosis was often made on a single test. The possible fallacy of this and its extent, when a finding of non-patency is obtained, has just been referred to: the incidence of non-patency was then 38% (480 cases). Within recent times a much more strict minimal criterion has been established—namely, two negative insufflations and a negative hysterosalpingogram—the last 998 cases show an incidence of non-patency of 20.5%. This is believed to represent very closely the real figure.

A negative insufflation is generally taken to mean that gas fails to pass at 200 mm. Hg (the usual upper limit). In the course of numerous experimental tests, using 250 mm. Hg as the upper limit, I have often found that gas has passed between these limits. We have not encountered any ill effects or sequelae since adopting as a routine the pressure of 250 mm. Hg as the upper limit. Moreover, insufflation experiments using high pressures have been conducted in the course of abdominal operations for tubal sterilization or salpingostomy. In two cases of tubal blockage (tuberculous) a sustained pressure of 250 mm. Hg was observed to make no apparent impression on the tubes, and in another similar case the finding was the same with a pressure of 320 mm. Hg. (In nine other cases in which the tubes had been artificially blocked at their fimbriated ends by clamps the results were inconstant; in some cases ballooning of the tubes occurred at pressures below 100 mm. Hg.) It is suggested that greater accuracy of results (and possibly therapeutic success) would be obtained if the routine upper limit of pressure of 200 mm. Hg were raised to 250 mm. Hg.

The investigation of the tubal status of young unmarried women affords an interesting comparison. Altogether 236 consecutive unselected subjects (aged from 13 to 39 years) were insufflated at the time of operation for a gynaecological complaint and in all but four the tubes were permeable to gas at the first test. Three of the four had insufflation repeated at a later date without anaesthesia and the tubes were then found to be permeable to gas. The fourth patient could not be traced.

#### Therapeutic Aspects of Insufflation

Of the 902 patients traced—primary sterility only—271 (30%) became pregnant. The main features may be summarized as follows: (1) 164 were under 30 years of age and 107 were 30 years or older when coming first under observation. (2) The oldest was 42 years (married four years)—she miscarried at two months. (3) 136 had been married three years or more, 47 five years or more, and one 13 years (aged 35). No patient who had been married for a longer period than this became pregnant. (4) Tubal

insufflation had been performed in 262 cases; patency had been diagnosed in 231 and non-patency in 31 (all the latter cases were early ones in the series, insufflated once only)—24 under anaesthesia and seven without it. The fallacy of a single finding of non-patency is apparent from these figures. (5) Pregnancy terminated in miscarriage in 50 (18.5%) of the 271, but seven subsequently had a full-term child; one further case had pregnancy terminated (in another hospital) for hyperemesis gravidarum, and another two for toxæmia (one at four months and the other at seven months); one patient had a tubal pregnancy four years after insufflation. Thus 224 (83%) bore a child (two cases had twins); one patient had three miscarriages and five patients had two—none has since gone to term. (6) The sex incidence of the infants was 49% male and 51% female. (7) *Time elapsing between insufflation and conception* (259 cases: in three of the 262 cases insufflated the date of occurrence of pregnancy could not be accurately ascertained).—Twenty-three pregnancies occurred within one month after insufflation, 22 within two months, 24 within three months, seven within four months, 17 within five months; and 15 within six months: a total of 108. Thus, 69 (27%) of 259 pregnancies occurred within three months of insufflation and 108 (42%) within six months. During the following six months 47 became pregnant.

Rubin (1945) reported a personal series of 573 cases of primary and secondary sterility that became pregnant after insufflation. Within three months of the test 265 (46.2%) became gravid, and within six months 378 (64%). Of 250 patients who were personally delivered 81.8% had full-term children. (This corresponds closely to my figure of 83% in 224 cases, already mentioned.)

#### Tuberculous Endometritis and Sterility

The examination of endometrium in a consecutive series of 1,898 cases of primary sterility has shown unsuspected tuberculosis in 100 (5.3%). In the first instance this finding was largely an accidental discovery in endometrium removed primarily with a view to the diagnosis of anovulation. The histological characters of the lesion and the proofs of its tuberculous nature have been fully described elsewhere. Space does not permit the discussing of these or the detailing of the biopsies and findings in each of the 100 cases, but the following essential points may be dealt with in more detail: (a) the high incidence of endometrial tuberculosis in sterility; (b) the evidence that this estimated incidence is minimal; (c) the duration of the disease; (d) the effect of curettage—the rate of recurrence; (e) the results of search for tuberculous history and for other tuberculous lesions; (f) the effect of bilateral salpingectomy; (g) the hopeless fertility prognosis; (h) the relationship of endometrial tuberculosis to tubal occlusion.

(a) *The High Incidence of Endometrial Tuberculosis in Sterility.*—Sutherland (1943) has reported the finding of tuberculosis in 100 endometria in a consecutive series of 7,670 cases (including sterility cases), giving an incidence of 1.3%. It has already been pointed out that in my series of 1,898 endometria the tuberculosis incidence was 5.3%. Further analysis shows that endometrial tuberculosis is 15 times more common in sterile than in fertile women.

(b) *Evidence that this Incidence is Minimal.*—In 58 of these patients biopsy was performed more than once: when performed twice it was tubercle-positive on both occasions in 7 patients, and once positive and once negative in 12 cases; when performed either three or four times in the remaining patients, on 40 occasions it was tubercle-positive and on 24 tubercle-negative. Obviously, therefore, in many instances no evidence of the disease was found on single occasions. This occasional absence of evidence prompted further study of the endometria concerned. The paraffin blocks were re-embedded

and reorientated so that further sections might be taken from the other end of the biopsy material. This was done in 12 blocks from six patients. Numerous sections were examined, but there was no evidence of tuberculosis in any of them, although many showed histological evidence of chronic endometritis. Further light in this connexion was shown by the examination of additional sections of the definitely positive biopsies: in several of the cases sections showed no evidence of tubercle follicles, although, in some, plasma and round-cell infiltration was marked. Moreover, in several cases in which biopsy material was divided negative histological findings and positive guinea-pig inoculation results were obtained. It may be concluded, therefore, that absence of signs of tuberculous endometritis in any given biopsy is not evidence that the disease is not present, and that the incidence figure of 5.3% in my series is an absolutely minimal one. Moreover, in any case of primary sterility showing histological evidence of chronic endometritis further sections should be examined for evidence of tuberculous lesions, and if such evidence is not found additional biopsy should be performed. *Chronic endometritis in case of primary sterility should be regarded as suggestive of tuberculous infection.*

(c) *Duration of the Disease.*—Endometrial tuberculosis was found to be still in evidence after the following lengthy periods of time in seven patients: 13, 7½, 7, 7, 6, 6, and 5 years.

(d) *Effect of Curettage.*—Although it was considered most improbable that even very thorough curettage of a tuberculous endometrium would "cure" the condition, studies were carried out to observe the recurrence of the tubercle follicle and to determine its time interval. Four sterile patients were investigated. The findings may be summarized: tuberculous endometritis was found to have recurred at the following intervals of time after thorough curettage under anaesthesia: 34 days, 0 days, 3 months, and 27 days. There seems little doubt, therefore, that reinfection of the endometrium rapidly recurs after curettage. The question naturally arises as to the location of the focus from which reinfection occurs. Two lines of investigation were pursued: (1) careful inquiry was made into the previous history of the patient, and a detailed search for tuberculous lesions in other organs of the body was carried out, and (2) the effects of bilateral salpingectomy were studied.

(e) *Results of Search for Tuberculous History and for other tuberculous Lesions.*—In none of these cases was pelvic tuberculosis diagnosed or suspected when endometrial biopsy was performed. Almost all were noted as enjoying good health, and, with the exception of seven cases, there was no history suggestive of tuberculosis in childhood or adolescence: the seven exceptions were: (1) aged 28, "pleurisy and gastroenteritis" at age of 17; (2) aged 29, "tuberculous gland of neck" at 5 years; (3) aged 24, "tabes mesenterica" at 14 nine months in sanatorium; (4) tuberculous gland removed with appendix at age of 17; (5) aged 23, "tuberculous peritonitis" at 14 (2½ years in sanatorium); (6) aged 26, "in sanatorium for ten months at age of 16—menstrual trouble"; and (7) aged 26 (laparotomy two years earlier in another hospital revealed abdominal tuberculosis). Radiographs of the chest were carried out in 51 of the 100 cases; all but eight were negative. Three of the latter showed active apical tuberculosis of both lungs, and the others had calcified plaques or old healed apical lesions. A large number of abdomino-pelvic radiographs were done, until it was seen that many cases of confirmed tubal tuberculosis showed no calcified glands, whereas many control cases (not sterility ones) did.

(f) *Effect of Bilateral Salpingectomy.*—In August, 1942, a patient complaining of dyspareunia and sterility was curetted under anaesthesia and insufflated. Gas failed to pass at 90 mm. Hg; the endometrium showed unmistakable tuberculous foci. Two years previously she had had a pelvic operation in another hospital. Inquiry there elicited the information that the operation had been "bilateral salpingectomy"; histological examination confirmed the diagnosis of tuberculous salpingitis. As the finding of tuberculous endometritis after salpingectomy was diametrically opposed to that of Solomons (1935)—namely, "removal of tubercular Fallopian tubes means cure of tuberculous endometritis"—it was felt that further investigation of the matter was essential. In three patients, complaining of primary sterility only, in which there was tuber-

culous endometritis but no palpable adnexal swellings, bilateral salpingectomy was performed. The following are the details:

*Case 1.*—Mrs. R., aged 23. On Jan. 7, 1944, curettage and bilateral salpingectomy were carried out; the fundus uteri and interstitial portions of the tubes were not excised. Biopsies were subsequently performed 12 and 14 weeks later. On both occasions tuberculosis of the endometrium was present. This finding confirmed that of the previous case—that removal of the Fallopian tubes did not cure endometrial tuberculosis—but it did not exclude the possibility that reinfection of the endometrium might occur from the intact interstitial portions. It was therefore decided to do a complete bilateral salpingectomy, including the fundus uteri, when opportunity offered. The following two cases were so treated.

*Case 2.*—Mrs. F., aged 39, had a complete bilateral salpingectomy and fundectomy performed on Aug. 7, 1944. Curettage three weeks later and biopsies two, three, and four months later all showed tuberculosis of the endometrium. Biopsy was again performed on Aug. 21, 1946—that is, two years after operation—and tuberculous endometritis was present.

*Case 3.*—Mrs. L., aged 26, had a complete bilateral salpingectomy and fundectomy on Aug. 18, 1944. A biopsy performed two years later showed no evidence of tuberculous infection. This was not very surprising in view of the fact that the endometrium removed on five occasions in this patient prior to salpingectomy had shown tubercle follicles on three occasions but none on two.

These findings prove that, despite widely accepted statements to the contrary in the literature, removal of tuberculous Fallopian tubes does not cure endometrial infection.

(g) *The Hopeless Fertility Prognosis.*—A follow-up of 72 patients who had been under observation for more than one year has shown that, of 63 traced, not one sterility patient with endometrial tuberculosis became pregnant. Many have been followed up for from five to eight years and one for 13 years. Salpingostomy has had no successes. Although rare cases of pregnancy in the presence of tubal tuberculosis have been recorded, it would seem that in cases of endometrial (and tubal) tuberculosis the restoration of fertility is wellnigh hopeless.

(h) *Relationship of Endometrial Tuberculosis to Tubal Occlusion.*—I have left to the last consideration of the incidence of tubal occlusion in cases of endometrial tuberculosis: in 89 of the 100 cases tubal insufflation was performed and showed non-patency in 55 (61.8%). This high incidence of occlusion suggested the possibility of an unsuspected subclinical tuberculous salpingitis as a source of reinfection of the endometrium, and this conception in turn led me to reconsider from a new angle the possible aetiology of tubal occlusion.

### The Causation of Tubal Occlusion

There is, of course, no need to discuss tubal occlusion arising from gross tubal damage. The problem under consideration at the moment is the aetiology of blockage in tubes which seem normal on bimanual examination. In the past it has been widely accepted that in most instances the occlusion of the lumen results from gonococcal salpingitis, or from tubal infection from a near-by pelvic lesion (particularly appendicitis), or from congenital hypoplasia. My finding (Sharman, 1944)—since confirmed by other investigators—that endometrial tuberculosis is unexpectedly common (5.3%) in sterile women suggested the possibility that tubal tuberculosis of a degree not sufficient to be grossly recognizable except on laparotomy might be responsible for a much greater number of cases of tubal non-patency than is generally recognized. This led me to undertake certain investigations which I shall now discuss.

#### (a) Gonococcal Salpingitis as a Cause of Occlusion

There is very little positive proof that, apart from gross tubal damage, gonococcal salpingitis is a common cause of tubal occlusion. It is unusual to obtain a history of any pelvic illness in a series of sterile women, and, more impor-

tant still, there is little direct evidence that the infection ever reaches the tubes in more than a very small percentage of cases of gonorrhoea. There are few published data on this point, but with the co-operation of the Public Health Department of Glasgow I have been able to obtain the following figures, which, I think, are of considerable significance. The records of acute gonorrhoea in women who attended the principal clinic from 1930 to 1937 were surveyed with special reference to the incidence of pelvic involvement. There were only five cases of the latter in a total of 540 patients. A follow-up of the five cases revealed that one subsequently had three pregnancies, but that the others had not become pregnant. During the years 1938 to 1942, inclusive, the total number of new cases of acute and chronic gonorrhoea in females over 15 years of age attending the principal Glasgow municipal centre amounted to 987. Among these were 26 cases of acute pelvic involvement (2.6%). In 775 consecutive cases of acute gonorrhoea during the same period there were ten (1.3%) cases of salpingitis. Very careful observations made on this point show that since June, 1941, a total of 2,195 cases have been treated, of which only 22 (1%) have developed an acute febrile pelvic lesion.

Even if it is admitted that a number of mild pelvic infections may have occurred, the general conclusion appears to be that the gonococcus is seldom responsible for the occlusion of tubes which are not palpably thickened. This, of course, is not in accordance with the widely accepted view and usual teaching, but support for it is found in the statement by Siegler (1944) that a history of gonorrhoea occurred in only 3% of 397 cases where the tubal factor was investigated, and in Halbrecht's (1946) declaration that gonorrhoea is rare in Palestine, although tubal occlusion is one of the main causes of sterility in his cases.

#### (b) Congenital Hypoplasia as a Cause of Tubal Occlusion

The significance of this factor was first described and stressed by Clauberg in 1938; he maintained that in cases of infantile uterus the tubes often shared in the developmental deficiency and are consequently impermeable. There has been a vague general acceptance of Clauberg's theory, but I am not satisfied that it is correct. The following arguments may be raised against it: (i) Clauberg's evidence was almost entirely radiological, apart from investigations on lower animals; (ii) a large number of cases of uterine hypoplasia have shown normal tubal patency and function on kymographic insufflation; (iii) radiographs often show patency in tubes presenting the long, thin, tortuous features of the "congenital hypoplastic" type; (iv) in a small series of cases showing definite tubal blockage and treated by Clauberg's method with oestrogenic hormone none showed patency after treatment, as claimed by him; and (v) tubal blockage associated with uterine hypoplasia need not be due to tubal hypoplasia but may arise from other causes—for example, subclinical tuberculosis—as will be discussed later. It is not disputed, of course, that follicular hormone produces proliferation of the mucous membrane and general hyperaemia of the Fallopian tubes, as Clauberg has shown, but the point at issue is whether the hypoplastic or infantile tube is essentially a non-patent structure or not. I have approached this question from three angles: (1) a histological study of the pre-pubertal tube, (2) insufflation of the tubes of the foetus and infant, and (3) kymographic insufflation in an unselected consecutive series of young unmarried women.

1. *The Pre-pubertal Tube.*—Fallopian tubes were removed post mortem and sectioned from cases of the following ages: a 7-months foetus; a foetus stillborn at term; children aged 2 days, 10 weeks, 3 months, 4½ months, 7 months, 16 months, 3 years, 4 years, 8 years, and 10 years. Sections were cut

through fimbrial, ampullary, and isthmic portions. The appearance of the tubes throughout the series is that of a pale structure, and there is no evidence that canalization of the Müllerian ducts is often, if ever, incomplete.

2. *Insufflation of the Tubes of the Foetus and Infant.*—The material studied was obtained post mortem from a series of stillborn infants and neonatal deaths in the Glasgow Royal Maternity Hospital and from fatal cases in the Royal Hospital for Sick Children, Glasgow. The examination was carried out as soon as practicable after death, usually within a few hours. Twelve cases were insufflated and all showed tubal patency.

3. *Insufflation in Unmarried Women.*—This has already been referred to in considering the tubal status. It will be recalled that 236 young unmarried girls were insufflated. The test showed that in all but four cases the tubes were permeable to gas at the first test. Three of the four had insufflation repeated at a later date without anaesthesia, and the tubes were then found to be permeable to gas. The fourth patient could not be traced.

It may therefore be stated that the evidence obtained from these three separate lines of inquiry suggests that impermeability of the tubes is seldom a congenital defect.

Irrespective of the tubal factor, uterine hypoplasia *per se* has for long been blamed for infertility. There is no convincing evidence that this is so, although minor degrees of underdevelopment are often found on bimanual examination. Arguments against its importance are: (1) the common clinical observation of pregnancy ensuing in untreated hypoplastic uterus; (2) the finding that increase in uterine size after oestrogenic treatment may not be followed by pregnancy; (3) the fact that pregnancy can develop in a Fallopian tube or an ovary suggests that complete maturity of the uterus is not essential.

In order to investigate the matter further a follow-up was made in 1946 of all the unmarried patients between the ages of 16 and 36 who were in the Royal Samaritan Hospital for Women, Glasgow, during the years 1936 inclusive. These patients were divided into two groups: (a) in which the uterus was described as of normal size and (b) in which the uterus was hypoplastic. The investigation embraced all hospital units, the diagnosis having been made by one of five gynaecologists. The results were as follows: (a) Uterus normal: of 113 patients traced 63 had married and 42 (66.6%) of them had conceived. (b) Uterus hypoplastic: of 147 patients traced 78 had married and 70.5% of them had conceived.

It would appear, therefore, that minor degrees of uterine hypoplasia have but little relation to infertility and are purely an incidental finding. It is quite different with minor degrees (often associated with narrow vaginal introitus or canal), which are uncommon but which seriously affect fertility prognosis. (The relative incidence of these conditions obtained in a survey of 863 consecutive cases of primary sterility was: 437 showed a minor degree and 426 a major degree.)

#### (c) Subclinical Tuberculous Salpingitis as a Cause of Tubal Occlusion

It will be remembered that in the course of this investigation unsuspected subclinical endometrial tuberculosis was found in a relatively high proportion (5.3%) of sterile women. Now, since endometrial tuberculosis is almost invariably secondary to tuberculous infection of the tube, it is highly probable that subclinical tubal tuberculosis is present in at least 5.3% of sterile women. Further, it is well known that endometrium often escapes infection even when the tubes are the seat of gross tuberculous lesions, and therefore highly probable that in sterile women the incidence of subclinical tubal tuberculosis is much higher than 5.3%. This suggests the possibility that subclinical tubal tuberculosis of the tube may be the cause of occlusion in a case which seems normal to palpation. An endeavour was made

tain positive evidence on this point, and two separate methods of investigation were utilized. First, the incidence of tubal occlusion in cases of endometrial tuberculosis was studied, and, secondly, histological proof of tuberculous infection was looked for in tubes which had been found to be blocked.

The incidence of tubal blockage in endometrial tuberculosis was found to be 61.8%. This contrasts with an incidence of 26.2% over the total series of 1,478 sterile women, including those in whom endometrial tuberculosis was absent.

The second line of evidence was more difficult to obtain, since only a small number of women were willing that an attempt should be made to restore patency of the tube by operation. So far I have had an opportunity of studying the histology of such tubes in 14 cases, a piece being removed in the course of salpingostomy (or of salpingomy in the cases already described). The series is too small from which to dogmatize, but, nevertheless, it is interesting that 12 of the 14 specimens showed tuberculous infection. Moreover, in the two negative cases (histologically) the appearances at operation were highly suggestive of tuberculous salpingitis. One further case (bilateral blockage) showed tubercle follicles in the distal portion of the blocked tube.

It must be borne in mind that, as in the endometrium, tuberculous infection is almost invariably a focal disease, and a single routine section may fail to show its presence though further sections may be positive.

In view of these findings I feel justified in putting forward the view that tubal blockage is in a considerable number of cases due to subclinical tuberculous salpingitis.

### Conclusion

There are many problems in the investigation of sterility, but I have been able to deal with only a few, but it is hoped that attention has been drawn to certain aspects in which some progress appears to have been made. The problem, however, is large and much exploration remains to be done.

## LYMPH-GLAND BIOPSIES FOR SUSPECTED BONE AND JOINT TUBERCULOSIS

### AN ANALYSIS OF 100 CONSECUTIVE CASES

BY

G. P. ARDEN, M.B., F.R.C.S.

AND

J. C. SCOTT, M.D., M.S., F.R.C.S.

(From the Wingfield-Morris Orthopaedic Hospital, Oxford)

Valls, of Buenos Aires (1933), first published the results of lymph-gland biopsy as an aid in the diagnosis of tuberculous bone and joint disease, and Seddon (1939) was the first to do so in Great Britain. More recently other papers on the subject have been published by Agerholm-Christensen (1941), Gellman (1941), and Webster (1942), but up to the present no large series of cases has been reported.

The object of our investigation was to determine the proportion of positive findings in 100 gland biopsies undertaken to assist in the diagnosis of arthritis in various joints, to report the subsequent clinical progress in these cases, and to describe the results of examination of lymph glands removed incidentally in the course of other operations or post mortem. Valls reported 19 gland biopsies (various joints) with 15 positive results; Seddon described 18 for the knee only, with 15 positive results; and Webster obtained 10 positive results out of 15 gland biopsies (several joints). None of these authors has produced a comparable series of incidental gland biopsies.

### Lymph Drainage from Joints

Information on this subject is very conflicting. Most of the experimental work has been carried out on rabbits (Key, 1926; Kuhns, 1933), and there is no real evidence that the drainage in man follows a similar pattern. Webster (1942) in his report of 15 biopsies discusses the subject at some length and points out evident contradictions between the experimental findings, the accepted anatomical description of lymph drainage, and the results of biopsies. Trueta and Barnes (1940) showed that a considerable lymph flow was stimulated by a passive joint movement in cats, a finding which might be of assistance in determining the paths of flow from various joints.

That there may be different lines of drainage from one joint, depending on what tissues are involved, must also be borne in mind. We know very little about lymph drainage from bone: superficial tissues usually drain to the first chain of superficial glands. The fact that this form of biopsy has been more helpful in arthritis of the knee than in other joints may be due to the fact that tuberculous disease in the knee is usually confined to the synovial membrane in its early stages and is seldom a primary osseous infection. Tables I and II show the exact sites of glands removed in disease of various joints.

### Technique

Before discussing the results a brief review of the technique employed is essential. Iliac-gland biopsy was the routine for hip and upper femoral disease, inguinal-gland biopsy for infections of the knee, ankle, and foot, and axillary biopsy for all joints of the upper limb. The youngest patient was aged 2 years and the oldest 69. General anaesthesia was considered the most satisfactory method, and was used in all cases. Inguinal-gland biopsy

The British Association of Physical Medicine has issued some suggestions on the place of physical medicine in the National Health Service. In teaching hospitals there should be a director of physical medicine, with a trained staff and trainees, to conduct treatment, teaching, and research. The department would co-operate with the disablement resettlement officers of the Ministry of Labour. Similarly there should be a director and staff in charge of a special department in central hospitals. In district hospitals there should be a physical medicine department under the direction of a visiting specialist, and domiciliary physiotherapy should be based on the district hospitals. Physiotherapy should not be provided at health centres, since there will be a serious shortage of physiotherapists for a number of years. The B.A.P.M. draws attention to the fact that too many patients who are fit to return to work, yet still require treatment, waste time and money attending physiotherapy departments in the day-time: facilities for treatment in the evening should be arranged. For patients who must make long journeys from home to hospital and for whom the value of treatment is thereby diminished, transport should be arranged by voluntary organizations or at the public expense.

was performed through either an oblique or a vertical incision over the fossa ovalis. The termination of the saphenous vein was exposed and a superficial gland removed from this region; a deep gland was usually found lying between the saphenous and the deep femoral veins.

Iliac-gland biopsy was performed through an oblique incision in the iliac fossa, the peritoneum was stripped forward, and the iliac glands were sought in the region of the bifurcation of the common iliac artery. In one patient with hip disease an obturator gland was removed and this gave a positive result. In one case an iliac-gland biopsy was performed for a knee infection, and in another an inguinal-gland biopsy in a patient with hip disease; neither was positive.

Axillary biopsy was performed through a vertical incision over a palpable gland, which was dissected out and removed. Half of each gland removed was put into 10% formal saline for histological examination and the other half into saline for culture and guinea-pig inoculation.

### Results

Gland biopsy for this purpose was first performed at this hospital in 1936, and since May, 1939, it has been done in most cases of suspected tuberculosis. The cases analysed were dealt with during the period May, 1939, to December, 1946; for various reasons complete details are not available in every case. One hundred cases have been analysed; 62 patients were below the age of 21 (29 females, 33 males) and there were 38 adults (17 females, 21 males). Two patients have died, one from miliary tuberculosis (aged 29) and the other from cerebral haemorrhage (aged 67). In five cases no gland was found at operation (all iliac), but in two of these an inguinal-gland or obturator-gland biopsy was done instead. In two cases no result can be found of the gland-biopsy result. A histologically positive gland biopsy was obtained in 32 cases, and in a further case the guinea-pig inoculation was positive, although no histological evidence of tuberculosis was found in the gland. A guinea-pig inoculation was performed in only 47 cases; if this had been carried out in every case and if serial sections of the gland had been examined and culture performed, it is probable that the number of positive results would have been greater. No positive results were obtained in the few cases cultured. In five cases the gland histology and guinea-pig inoculation were both positive; in one case the histological report was positive and the animal inoculation

was negative and in the other it was not done. In three cases, the deep inguinal gland proved to be positive histologically while the superficial inguinal gland was negative; in one case the opposite occurred; and in three cases both superficial and deep glands were positive.

Of these cases 59 were regarded as tuberculous on clinical grounds; 35 were regarded as non-tuberculous; in two there was some doubt. Four cases were too recent for positive assessment. Nine cases, all in the knees, were proved to be tuberculous by examination of the synovial fluid, synovial membrane, or bone (following excision), and one was indefinite; in seven out of these nine cases the gland biopsy was negative. In five cases (see Table II) positive at gland biopsy the joint recovered over two-thirds of the normal range of movement, and in one of these recovery was complete. In none of these five cases has there been any definite confirmation of the diagnosis by other means.

TABLE II

Case	Age (yrs.)	Skiagram	Joint	Highest E.S.R.	Clinical Progress
1	12	Acetabular focus	L. hip	27 mm.	2/3 movement 3 yrs. after
2	13	Decalcification	L. hip	10 "	2/3 " 6 " "
3	10	"	L. hip	17 "	2/3 " 5 " "
4	10	Epiphyseal focus in femur	R. hip	45 "	2/3 " 2 1/2 " "
5	6	Nil	L. knee	5 "	Normal knee 4 " "

In 10 cases with a positive gland biopsy the highest erythrocyte sedimentation rate while in hospital was 10 mm. or less; of these 10 cases three would not be regarded as tuberculous on clinical grounds alone. In this series there are records of 47 Mantoux and/or patch tests: 36 were positive, and of the 11 negative three were adults. All 33 positive gland biopsies were positive to a Mantoux or patch test. In only 17 of the 33 positive gland biopsy cases did skiagrams show definite changes, that is, joint destruction or a bony focus. Of 22 biopsies done within three months of the onset of symptoms 11 were positive. Twenty-three positive results were obtained in the 62 cases under 21, and 10 positive results in the 38 adults.

TABLE III.—Control Series

Natural .. ..	14	11	1
Scarred .. ..	20	5	2
Fibrosed .. ..	11		
Fatty infiltration .. ..	6	0	0
Tuberculosis .. ..	0	0	1

Over a period of three months 71 inguinal lymph glands were removed—60 at necropsy and 11 during the course of operations for other conditions, mostly herniotomies. Table III shows the results. Only one of this control series had tuberculosis of the gland. In that series there are two points worthy of note. The first is the age distribution, the second the number reported as scarred or fibrosed. We include these figures for the control series as they are of interest; but we do not feel that any definite conclusions with regard to the value of adenopathy can be drawn from them, and we propose to continue the series, including only the younger patients, in an attempt to learn something about the cause of the scarring which is so common in the older age group. In reporting on this series the pathologists point out that although there is no definite evidence of tuberculous infection in these glands it is not possible to state definitely that the scarring is not due to old healed tuberculosis.

### Discussion

The importance of all ancillary methods of narrowing down the differential diagnosis in arthritis of every

\* No gland removed in three cases.

† No record of result in these two.

In five no iliac gland was found; 1 obturator (+) and 1 inguinal (—) gland were removed instead in two cases.

lotion negative, while in another the opposite state of affairs existed. In two cases the histology was such that, although it suggested a tuberculous infection, no definite opinion could be given; in one of these the guinea-pig inoculation

needs no emphasis. Unfortunately many of the procedures upon which the surgeon or physician must rely are not altogether reliable.

The removal of regional lymph glands as an aid to diagnosis in chronic arthritis of uncertain origin is a comparatively new procedure and the degree of accuracy is not well established. Most of the series of cases that have previously been published have been relatively small and the follow-up of short duration. Here we have been primarily concerned with three things: whether the right gland has been removed; whether the clinical course has borne out or contradicted the pathological findings; and, in an unselected series of apparently normal glands obtained from the living or at necropsy, the proportion showing tuberculous changes. So far as the first point is concerned there is not enough information available to give any reliable opinion, though it is obviously necessary to take both superficial and deep glands when the knee is involved. The one case of hip disease in which the iliac gland was negative and the obturator positive is worthy of note.

The accuracy of the procedure can be related only to the hip and the knee, as the numbers are too small in relation to the other joints. In the hip the clinical progress of the lesion in approximately one-third of the cases in which the biopsy was negative established a diagnosis of tuberculous disease, and in half of those in which biopsy was positive subsequent progress suggests that the lesion is not tuberculous. In relation to the knee-joint the findings are similar so far as the negative results are concerned, nearly one-third having been proved tuberculous; however, of the cases giving positive results one alone has progressed in such a way that a clinical diagnosis of tuberculosis is impossible.

It is likely, as has already been pointed out, that routine serial sections of glands and guinea-pig inoculations would increase the number of positive findings. As things stand at the moment it seems that no great reliance should be placed on a negative finding from the regional gland biopsy, and that if the result is positive it is likely that, in the presence of a suggestive clinical picture, this can be accepted as confirmatory evidence.

### Conclusion

Gland biopsy is a valuable accessory means in the diagnosis of tuberculous infection of bones and joints. There were 33 (56%) positive results in 59 cases of tuberculous infection—a lower rate than those given by other authors.

A positive biopsy does not necessarily mean that the joint is tuberculous.

A higher proportion of positive results appears to be obtained if the biopsy is done early in the disease—10 out of 14 cases (71%). (21 biopsies were done within three months, but only 14 of these cases could be regarded as tuberculous on clinical grounds.)

An early positive gland biopsy gives strong support to a diagnosis of tuberculous infection before any changes that can be shown by x rays are present.

As is well known, a normal erythrocyte sedimentation rate is of no value in excluding tuberculous disease of the joints, 10 cases out of 59 having shown a normal E.S.R.

Clinical findings and progress, x-ray appearances, gland biopsy, and E.S.R. must all be taken together to obtain the most accurate diagnosis in chronic bone and joint disease.

We are indebted to the surgeons at the Wingfield-Morris Hospital for their permission to review these results and for helpful suggestions. We are also grateful to Dr. A. H. T. Robb-Smith and the

pathological department at the Radcliffe Infirmary for help with the paper and for doing all the control series.

*Honorary Obstetrician and Gynaecologist, Radcliffe Infirmary,  
Oxford*

Abortion is the most common serious complication of pregnancy, with an incidence of probably 25%. It is responsible for a greater wastage of potential and actual citizens than any disease, for it carries a mortality of 100% for the foetus and is associated with grave risks to the life and health of the mother. It is estimated that 700,000 infants are lost annually by abortion in America and that 3,500 mothers die in the United States every year as a result of this complication (McCormick, 1944). It is true there is evidence to suggest that the incidence of foetal deformity is high in these cases, but none the less the loss of potentially healthy citizens is great.

The purpose of this paper is not to discuss the prevention of abortion but to consider its treatment once it has become inevitable, incomplete, or septic. For that reason the discussion is concerned only with the maternal aspect of the problem. Throughout the series analysed we have accepted the following criteria for the diagnosis of these three conditions: (1) An abortion was considered inevitable when bleeding was associated with uterine contractions and dilatation of the internal os. (2) An incomplete abortion was diagnosed when bleeding persisted following the abortion and examination revealed a bulky uterus, usually with a patulous cervical canal, or when it was known for certain by inspection of the material passed that placental tissue had been retained. The subsequent removal or passage of placental fragments confirmed the diagnosis. (3) An abortion was considered septic when it was associated with pyrexia for which no other cause was found, offensive or purulent discharge, or evidence of pelvic inflammation. It should be noted in this respect that on occasion there is pyrexia and even hyperpyrexia during the process of spontaneous evacuation of a uterus with no preceding or subsequent evidence of uterine, pelvic, or general infection. Such cases were not included as septic abortions in the series analysed.

The recognized immediate dangers to the mother are death or serious illness as a result of haemorrhage or infection, and the following are figures given by different authorities as an assessment of the extent of these dangers. McCormick (1944) states that in America 25% of maternal deaths are due to abortion and that five in every 1,000 mothers who abort die as a result. Parish (1935) states that in 1933 463 maternal deaths were registered in England and Wales as being due to abortion, and

23% of these were attributed to haemorrhage. It was estimated from the Statistical Review of the Registrar-General for 1937 (p. 149) that 21% of all maternal deaths were due to abortion and 29% of maternal deaths from sepsis were due to septic abortion.

There are two main schools of thought concerning the treatment of abortion once it has become inevitable or incomplete. Those who may fairly be called the "non-interventionists" believe that if left alone the uterus will ultimately empty itself, and if it is allowed to do so the mother is subjected to the least possible risk. F. J. Browne (1946) advocates this attitude to treatment and quotes the work of Winter, Walthard, Dietrich, and Dubrowitsch in support of his statement that the mortality is twice as high with active as with conservative treatment. It should be noted, however, that all the results referred to were obtained before the days of specific chemotherapy. Surgeons and departments subscribing to this view require a great many gynaecological beds—or else refuse to admit abortions at all—because it often takes several weeks for an abortion, even early in pregnancy, to be completed in this way. As a result of this the anomalous situation arises that many teaching units in gynaecology, and even some special hospitals for women, refuse to admit abortion cases because the beds necessary for their treatment cannot or will not be offered.

The second school may be described as the "interventionists." They believe that all inevitable and incomplete abortions which are not rapidly and spontaneously completed should be treated by surgical evacuation of the uterus. This school requires many fewer beds, for with this treatment the stay in hospital is relatively short. This fact is not of course an argument in favour of the method unless it can be shown that in principle and practice it is at least as safe as that advocated by the "non-interventionists." We believe this can be proved.

### The Case for Intervention

Now, it has for long been accepted by our surgical colleagues that a wound heals most rapidly when it is cleansed of non-viable debris. In traumatic surgery the principle of treatment is to excise dead tissue and to leave vital raw areas for healing. We suggest that in gynaecology and obstetrics there has been a tendency to ultra-conservatism in the treatment of gestational products retained *in utero*. The wound at the placental site—for wound it is—has been credited with physiological properties to which it is not entitled. It has no magical powers of rapid healing when its surface is covered with adherent necrotic debris. Necropsy rooms yield ample proof of this fact. There is even the probability of secondary infection resulting from this retained material, but this aspect of the problem is now being studied separately and will be the subject of a later publication.

Believing that the principles of wound treatment accepted in general surgery should be applied to the treatment of abortion, we instituted an interventionist attitude as the basis of treatment for all cases of inevitable and incomplete abortion admitted under our care to the Radcliffe Infirmary, Oxford. Impressed by the early results, we have continued this treatment for eight years and now present a brief analysis of the work done. Before instituting this routine one of us (J.S.) had considerable experience of the conservative attitude during resident appointments in two separate teaching units elsewhere.

### A Series of Cases Treated Surgically

The series now analysed consists of 600 consecutive cases treated surgically by us in the wards of the Radcliffe Infirmary and associated private beds, and by "flying-

squad teams" for which we were responsible. This series does not include 58 cases of threatened abortion, spontaneous complete abortion, and missed abortion. There were no deaths in this group. Five hundred patients were treated in the general wards and 100 in private beds. Forty-two patients were frankly septic on admission and two of these were suffering from a generalized *Clostridium welchii* infection. Many were admitted in a critical condition as a result of extreme blood loss. When the occasion demanded it the patient was not transferred to the ward, but resuscitative measures were adopted in the casualty admitting-room, from which the patient was later taken direct to the theatre. Avoidance of unnecessary handling at this stage can be life-saving. On 71 occasions blood transfusion was administered, and this was always started before taking the patient to the theatre and was usually continued during the operation. In this way the exsanguinated patient was better prepared for operation, the risk of early transfusion reactions being masked by anaesthesia was reduced, and in the unlikely event of further extensive blood loss in the theatre there was a minimum of delay in replacing it. Rh-immunization is now avoided by preliminary testing, or is reduced to a minimum in extremely urgent cases by the use of Rh-negative blood. When the patient was suffering from extreme blood loss or shock it was often necessary, because of venous spasm, to give the blood under pressure as previously described (Stallworthy, 1939). When sepsis was present chemotherapy was begun, 2 g. of a sulphonamide being given as an initial dose, followed by 1 g. four-hourly. If haemorrhage was severe the patient was taken to the theatre without further delay; if it was not severe operation was postponed for twelve to twenty-four hours so as to obtain a satisfactory blood concentration of sulphonamide drug.

### Method

Once the patient was considered fit for operation the method of treatment was as follows. After a preliminary shaving and washing of the vulva and catheterization the patient was taken to the theatre, with the transfusion still running. In critical cases the anaesthetic was not started until the surgeon was gowned and ready to operate. Early in the series ether was used extensively, but this was replaced by hexobarbitone and then by thiopentone, as being less disturbing to the patient. Small doses, often only 0.25 g., were used. After the vulva and vagina had been swabbed with flavine in spirit, 1 in 1,000, the surgeon gently examined the pelvis to determine the exact position of the uterus and the state of the cervix. Failure to make this preliminary examination can result in the soft wall of a pregnant, retroverted uterus being perforated by sound dilators, or forceps. If the canal was patulous and placental tissue was in reach it was gently removed with the gloved finger. If not, then the cervix was exposed and an oxytocic drug was injected under vision into the cleaned cervix. Early in the series 0.5 ml. of "pituitrin" was used, but this was later abandoned in favour of 0.5 mg. of ergometrine. The change was made because of the generalized pallor and occasional sweating associated with the use of pituitrin and the rare but unnecessary fatalities when used in obstetrics. The length of the uterine cavity was gently measured with a sound. Unless it was already patulous, as was often the case, the cervical canal was carefully dilated to the size of a No. 14-16 Hegar dilator. Sponge forceps were then carefully introduced, opened, rotated through 90 degrees, closed and withdrawn. This was repeated until no further pieces of placental tissue were removed in this way. The cavity was then gently and thoroughly explored with a blunt flushing eurette through which passed a slow stream of detto (2 dr. to 1 pint—7 ml. to 568 ml.) at a temperature of 110° F.

(43.3° C.). This removed small fragments of tissue missed by the forceps and also stimulated uterine contractions, as shown by the rapid decrease in the length of the uterine cavity and the cessation of any bleeding. The cavity was then packed with a sterile 2-in. (5-cm.) gauze roll, which was removed six hours later. In septic cases the pack was impregnated with 10 g. of sulphathiazole powder. This pack serves a dual function. By promoting uterine contractions and by direct pressure on the placental site it safeguards against further bleeding during the stage of recovery from the anaesthetic, and with its removal it clears any small fragments or clot which if left could promote discharge, further haemorrhage, and possibly infection. Following the removal of the pack there was rarely more than a slight stained discharge, which usually ceased within forty-eight to seventy-two hours of the operation. The patient was allowed up thirty-six to forty-eight hours later, and if the home conditions were satisfactory was discharged on the third or fourth day. An attempt was made to discover the cause of the abortion, and advice was given on the necessary care during the early weeks of a subsequent pregnancy. Iron was given to combat anaemia secondary to the blood loss, and the patient was requested to report for a follow-up examination in a month.

### Results

There was one death in the series, the patient being one of the two whose abortion was complicated by a generalized *Cl. welchii* infection. This patient was considered to be moribund on admission. Abortion had occurred one month previously, and following this there had been daily haemorrhage until at the time of admission the haemoglobin level was 22%. Because of the state of collapse and the general appearance of the patient a provisional diagnosis of gas-gangrene infection was made, and treatment was instituted with serum in addition to transfusion and chemotherapy pending the report of the bacteriologist on the high vaginal swab. Death occurred within twenty-four hours of admission, and necropsy confirmed the presence of *Cl. welchii* septicaemia.

As already stated, it was common for patients with suitable home facilities to be discharged on the third or fourth day. The average length of stay in hospital was 7.5 days for the 500 non-private patients.

### Summary and Conclusions

Six hundred consecutive incomplete, inevitable, and septic abortions treated by surgical evacuation of the uterus followed by the insertion of a pack for six hours are analysed.

Forty-two patients were infected on admission—two with *Cl. welchii*. In all infected cases specific chemotherapy was started before evacuating the uterus.

Seventy-one transfusions were given; the average stay in hospital was 7.5 days; and there was one death in the series—mortality of 0.17%.

Surgical evacuation of the uterus in inevitable, incomplete, and septic abortion, if carefully performed, provides a safe and efficient method of treating the condition.

The method advocated reduces the length of stay in hospital—an important factor in these days of acute shortage of beds.

The low mortality (1 in 600) may be attributed to the method of treatment and to the fact that a team skilled in handling these cases was responsible for them. Routine treatment is easy to prescribe, but on the nice decision of when to administer may hang the balance between life and death.

## WORK OF A TUBERCULOSIS CONTACT CLINIC FOR YOUNG CHILDREN, 1941-5

BY

F. J. W. MILLER, M.D., M.R.C.P.

(From the City Health Department, and the Department of Child Health, Royal Victoria Infirmary, Newcastle-upon-Tyne)

In Newcastle-upon-Tyne, where the mortality from tuberculosis has always been above the average for the country, 150 children under the age of 5 years died from that disease between 1931 and 1940. In 1941, therefore, as part of a policy of investigating the causes of death in infancy and early childhood, a clinic was established for the observation and care of children under the age of 5 years who were known to have been in contact with tuberculosis. The object was to obtain information concerning the mortality and morbidity of tuberculosis in children of families containing a notified case of the disease and to ascertain the relation which this bears to the total mortality and morbidity for the same age group within the city. With this information it was hoped that it would be possible to estimate the accommodation required in Newcastle-upon-Tyne for the care of such young children.

This clinic resembles closely the diagnostic clinic for childhood tuberculosis suggested in the British Paediatric Association Report in 1943, and it seems appropriate to give a preliminary survey of the first 4½ years' work in order to show the usefulness of the investigation and the part which a clinic of this nature can play in a city tuberculosis service. This report covers the period June, 1941, to December, 1945, and the children were under 5 years of age when first examined.

### Organization of the Clinic

The work is carried out by arrangement with the tuberculosis medical officer in a special clinic established in the children's department of the Newcastle-upon-Tyne General Hospital. X-ray facilities are available and parents are more willing to bring young children to such a clinic than they are to take them to a tuberculosis dispensary. Full information concerning children in infected families is sent each week to the clinic from the tuberculosis medical officer, and this is the starting-point for the observation.

For the first six months, until January, 1942, the homes of the children were visited by a health visitor of the City Child Welfare Department chosen for this work; the health visitor explained the purpose of the visit and did a tuberculin patch test. If the test was positive the parents were asked to bring the child to the clinic for clinical and radiological examination. At the beginning of 1942 this arrangement was changed. All the children are now visited and their parents are asked to bring them for examination (tram or bus fares are paid when this seems necessary). The patch test was abandoned and the intradermal Mantoux test (0.1 ml. of 1 in 1,000 old tuberculin) is used as a routine; every child is radiographed.

During the war years demands upon the time of mothers of young children became heavy, and especially so with illness in the house. From the outset, therefore, the work was organized to avoid waste of time in hospital or unnecessary return journeys to the clinic. The tuberculin test done at the first visit is read either by the health visitor calling at the house on the third day or by the doctor at the welfare centre nearest the child's home. When the result is known the clinical, radiological, and social findings

are correlated and a decision made concerning any action required; the parents are notified by letter of the results of the examination, and are told if we wish to discuss the matter further and when we wish to see the child again. For return visits a further letter is sent about seven days before the visit is due. At the same time a complete report is sent to the tuberculosis medical officer and the family doctor. The interval that elapses between visits is not fixed but is related to the risk under which the child is living.

So far the response of the parents has been very good and appreciative. Only 10% have failed to attend. A few have not been interested; one or two wished to have a "private opinion"; but the most common cause of failure seems to be fear of tuberculosis and unwillingness to face the possible consequences of examination. An explanation of the examination and of the skin test is made at the visit and everything is done to ensure that the parents understand its significance.

Failure to react to 1 in 1,000 dilution of old tuberculin by intradermal injection has been accepted as negative, and stronger solutions have not been used. Every care is taken in the technique of injection and the management of the individual child, but my experience has not coincided with that of Gaisford (1946), who states that this test can be used without disturbing the children. Indeed, I am sure that a tuberculin test which avoids the use of an injection is most desirable and is particularly important when repeated tests are required; the modified jelly test as described by Deane (1946) might be the best method of meeting this difficulty, and the intradermal test would be used only when the result of the percutaneous test was not conclusive.

Notification is always a difficulty, and in our work only cases admitted to hospital or sanatorium have been notified as suffering from tuberculosis. This difficulty has been discussed previously by Moncrieff (1945) and in the British Paediatric Association Report (1943). The blood sedimentation rate has not been used.

### Results

From June, 1941, to December, 1945, we received information concerning 569 children and we examined 520 at least once. Table I shows the frequency of exposure to

TABLE I.—Number of Children in Various Age Groups and the Types of Tuberculosis to which they had been Exposed

Age Group	Total in Group	Type of Tuberculosis in Index Case								
		Pulmonary	Lymphatic All Types	Serous Pleural Effusion	Bone	Abdominal	Renal	Miliary	Meningeal	Skin
0-1	109	88	5	8	3	3	—	1	—	1
1-2	96	72	12	5	4	1	—	—	—	—
2-3	101	55	11	19	13	2	—	—	—	1
3-4	115	88	8	10	5	3	1	—	—	—

	520	369	49	52	28	13	2	3	2	2

various forms of tuberculosis. Table II gives the results of the first tuberculin reaction in children in contact with pulmonary tuberculosis and shows that half those in contact with "open" pulmonary tuberculosis and one-fifth of those in contact with "closed" pulmonary cases were positive when first examined. At subsequent examinations 35 of these children were observed to become tuberculin-positive, but the difficulties and staff shortages of 1943 and 1944 made it impossible to obtain the complete tuberculin conversion numbers for the whole group. Of 142 positive reactors at the first examination 110 came from known sputum-positive cases and 32 from "negative cases"; of

227 negative reactors 103 were contacts of sputum-positive cases and 124 of sputum-negative cases. The fact that half the children examined after contact with open pulmonary

TABLE II.—The Results of First Tuberculin Test in Children in Contact with Pulmonary Tuberculosis

Age of Child	Index Case: Positive Sputum	Tuberculin Test		Index Case: Negative or No Sputum	Tuberculin Test		Total Tuberculin Positive
		Pos.	Neg.		Pos.	Neg.	
0-1	42	15	27	46	3	43	18 (20.5%)

	3	49	6	43	1	27	1	12	1	8

12 out of 151 were positive at the first examination and only six were subsequently known to become positive.

### Hospital Admissions and Mortality

Thompson (1944) has stated, and I agree, that there is little or nothing which can be done in hospital for children with symptomless primary tuberculosis which cannot be done in a good home, and the only reasons for admission to hospital are unfavourable home conditions or the absence of any other method of separation from infection. Under the circumstances which existed during the year 1941-5 we could not admit children to hospital or other institutions to prevent initial infection or further exposure and our criteria for admission have been clinical symptom such as cough, wheezing, and loss of weight, progressive extension of radiological shadows, bone tuberculosis, or extremely adverse social conditions during the early phase of tuberculous infection, when the condition is most likely to become generalized.

Of the group of 369 children who had been in contact with pulmonary tuberculosis 57 were admitted to hospital for one of the reasons given above and a further eight were admitted with acute disseminated tuberculosis or tuberculous meningitis. These 65 children represented at least 30% of all children under the age of 5 years admitted to city hospitals for tuberculosis within the same time.

The mortality of the same group of 369 children exposed to pulmonary tuberculosis has been 5% (19) to the end of 1945 (Table IV)—significant enough to make the use of the word "benign" in connexion with childhood tuberculosis a very dangerous procedure. Of the group in contact with pulmonary tuberculosis 17 died in hospital from proved tuberculosis, two died at home with illnesses which were probably tuberculous, and at a recent follow-up of the families concerned it was found that four other children who had not been examined because they were born after the original notification had died of proved tuberculosis.

neningitis. Thus in 320 families containing an adult with pulmonary tuberculosis there was a minimum of 21 deaths of young children in 4½ years.

TABLE IV.—*Age Distribution of Deaths from Tuberculosis Occurring in 369 Children Contacts of Pulmonary Tuberculosis Exposed Between June, 1941, and December, 1945 (Positive and Negative Sputum)*

Age at First Exposure	No. of Children Exposed	Deaths to December, 1945
0-1	88	8 (9.0%)
1-2	72	4 (5.5%)
2-3	55	2 (3.6%)
3-4	88	4 (4.5%)
4-5	66	1 (1.5%)
	369	19 (5.0%)

The distribution of the deaths in relation to the age of the child at first exposure is shown in Table IV, confirming the well-recognized fact that the risk of exposure is greatest in the first year and decreases as age advances, with a marked fall after the age of 2 years.

During the time under consideration there were 66 deaths from tuberculosis in the 18,000 children under 5 years in the city; 19 of these (30% of the total) were known to come from the small group of 369 at special risk following contact with pulmonary tuberculosis. Examination of the records of the 19 children who died showed that nine had been tuberculin-negative at the first examination, and eight of these were under two years of age.

### Discussion

The work here described was undertaken as an exercise in preventive paediatrics in an industrial community of 270,000 inhabitants in which infantile and child mortality has always been high. The problem was to find methods of reducing the deaths from tuberculosis in children of a particular age group, the majority of which were undoubtedly caused by the presence in the community or the household of adults with open pulmonary tuberculosis. Ultimately the child's only effective protection is by the separation of the infector from the community for as long as may be necessary to render him non-infective. This implies the maintenance of his family while he is away and the provision of suitable employment after his return. But his aim seems so far from realization in most areas that it is appropriate to consider if anything can be done to reduce the morbidity and mortality in the group at special risk—the children in home contact with pulmonary tuberculosis.

A large literature dealing with the effects of home contact on young children already exists; all the essential data concerning the risks are known. Where the logical conclusions of this knowledge have been applied, as in Sweden, the results obtained have proved beyond all doubt that the deaths of small children from tuberculosis can largely be prevented. It is difficult to know why these conclusions have not been applied in England or why the Swedish work has not received more attention, but the fact remains that little has been done by the public health services to provide care and treatment for this particular age group.

It has been shown repeatedly—in England by Cox (1929), in America by Brailey (1940), and by many other authors, quoted by Kayne (1935)—that children in households containing an adult suffering from pulmonary tuberculosis are subject to a much higher mortality from tuberculosis than that experienced by other children of their age group. Furthermore, all observers have agreed that the primary infection is most dangerous if acquired in the first year, that there is a considerable risk in the second year, and thereafter the risk falls to the age of 5 years. The least

dangerous period to acquire the primary infection appears to be between 5 and 15 years. Many figures have been compiled to show this, but it is sufficient here to quote only those of Bracuning and Neumann (1929), Table V. If, therefore, it is true that all individuals sooner or later acquire a tuberculous infection, it is equally true that they should not be allowed to do so in the first five years of life.

The problem of the young child in a tuberculous household is to devise methods of separating him from continued contact if he is free from infection when first examined or to consider what can be done to separate him from further infection if he has an active primary focus; it seems quite illogical to be compelled to wait until the child does become infected before arrangements for his care are possible. Sometimes separation can be accomplished by allowing the child to go to a relative; but the number of cases in which this is possible is not large, and this method of separation is often incomplete. Two other methods are available: admission to a home for infants or to another family group, the parents of which would act as foster parents

TABLE V.—*Mortality at Various ages: Exposure to Open Pulmonary Tuberculosis (Brauning and Neumann, 1929)*

Age when Contact Began (Positive-Sputum Contact)	No. of Cases	Tuberculosis Mortality	
		Within One Year	At end of Five Years
0-1 year	246	6.1%	8.1%
1-5 years	569	1.4%	1.4%
5-10 "	618	0.49%	1.4%
11-15 "	647	Nil	1.0%

until the danger of infection has disappeared. In Sweden both methods have been used, and out of his great experience Wallgren (1939) advises the infants' home rather than the foster parent. He considers the dangers of infection in a well-managed nursery are not greater than in a private house, and he finds parents are more willing to allow their children to enter institutions than to join other families. Another advantage of the institution is that if B.C.G. vaccine is used to produce an artificial temporary immunity the children can stay there for the requisite period of three months while the vaccine is given and hypersensitivity is developed.

In Newcastle-upon-Tyne during the period under consideration 227 children in contact with pulmonary tuberculosis were negative when first examined; even if the admissions to a home for infants had been restricted to those known to be in contact with open pulmonary tuberculosis it would have been necessary to offer approximately 103 places in 4½ years. To estimate the average length of stay is difficult, but the need could probably have been met by the provision of an infants' institution of 40 beds, the cost of which, apart from establishment and capital charges, would be approximately £4,000 a year. The foster parent scheme should, theoretically at least, be more satisfactory than the institution. It would cost approximately £3,000 a year, but it would be difficult to obtain enough suitable foster parents.

In Sweden B.C.G. vaccine has been widely used for the past 20 years and the Swedish workers consider that children who become tuberculin-positive after the administration of the vaccine acquire an immunity which enables them to resist infection under natural conditions for about two years. Recently the National Association for the Prevention of Tuberculosis and the Joint Tuberculosis Council have presented a memorandum to the Ministry of Health (Tytler, 1946), in which they urge trials of B.C.G. vaccine in England.

Our indications for the hospital treatment of infected children have already been given. The essential object of

special treatment is to give the child with a primary infection the best opportunity of resisting and then healing the lesion. In 4½ years 57 children were admitted to hospital from the contact group for clinical and social conditions. If more beds had been available at least 80 children would have been admitted, and I estimate that in Newcastle-upon-Tyne at the present time a tuberculosis contact clinic of this type requires the use of 10 hospital beds for children under the age of 3 years. This number does not include accommodation for children with acute disseminated tuberculosis and children over 3 years of age who can be sent to a children's sanatorium.

These estimates give some indication of the provision which I consider would be required to meet the problem of primary tuberculosis in young children of tuberculous families in Newcastle-upon-Tyne. The assumption I have made is that the present difficulty of removing the adult infector will not be changed materially in the immediate future; as, however, more beds become available in sanatoria and the economic provision for families is extended the need for special protection for children will be reduced proportionately. Until then the work of diagnostic clinics will, I believe, be a valuable part of the tuberculosis service if the case-finding mechanism is supported by the provision of hospital beds and methods of separating children from danger of infection. If there is no such backing then one can agree with Thompson (1944) that the examination of children as contacts is not of much value apart from clinical and epidemiological interest.

### Summary

The organization and work of a clinic for the examination of tuberculosis contacts has been described.

From June, 1941, to December, 1945, 520 children under the age of 5 years were examined: 369 contacts of pulmonary and 151 of other types of tuberculosis.

At the first examination 142 of 369 contacts of pulmonary tuberculosis were tuberculin-positive; of 151 contacts of other types of tuberculosis 12 were positive.

The mortality from tuberculosis in the 369 children in contact with pulmonary tuberculosis has been 5% to December, 1945.

In children under the age of 5 years 30% of the morbidity and 30% of the total mortality from tuberculosis occurred in a small group at special risk.

An attempt has been made to estimate the provision required to meet the needs of this group: (a) to separate the uninfected from further exposure; (b) to change the environment of the infected when this is necessary for either social or medical reasons.

I wish to thank Prof. J. C. Spence for criticism, Dr. G. Hurrell and Dr. E. G. Brewis of the City Tuberculosis Service for their co-operation, Dr. S. M. Livingston for continuing the work during the most difficult period of the war, and the health visitors, Misses F. M. Hatfield and E. Hann, for their constant enthusiasm and patience.

## RHABDOMYOSARCOMA CAUSING ACUTE RETENTION IN INFANTS

BY

ELLISON MINCHIN, F.R.C.S.

Assistant Out-patients' Surgeon, Royal Perth Hospital, Western Australia; Late Resident Surgical Officer, Royal Victoria and West Hants Hospital, Bournemouth

Rhabdomyosarcoma is rare, but two cases in which this growth caused acute retention in infants were admitted to the Royal Victoria and West Hants Hospital, Bournemouth, during 1944-5.

Nine cases of rhabdomyosarcoma of the urinary bladder have previously been reported, Case I below being the tenth. Seven of these occurred in infants aged from 3 days to 2 years. The remaining three were in adults of 23, 4 and 69 years. Rhabdomyosarcoma of the prostatic and prostatic region has been reported in 19 cases, and Case below is the twentieth. Although the origin of this growth is usually assumed to be in the prostate, Hirsch and Gasser (1944) suspect that it may belong to the class of similar growths which occur along the vas deferens.

The literature on both types of growth has been extensively reviewed by Khoury and Speer (1944), who also discuss the pathogenesis, pathology, and histology of these tumours.

### Case I

A 17-months-old male child was admitted to hospital on July 15, 1944, with a history of difficulty in micturition for more than four months. Apart from an inguinal hernia, which had been "cured" 12 months before by wearing a truss, he had not suffered from any ailments since birth until the onset of the urinary trouble. During the four months before coming to hospital his dysuria had been treated by circumcision and urinary sedatives, without relief.

On examination the bladder fundus was level with the umbilicus, forming a tense globular swelling. Rectally the bladder was found to be partly filling the pelvis. A straight skiagram revealed no opaque calculi in the urinary system. The blood urea was 51 mg. per 100 ml. Slow decompression of the bladder was instituted, but it was soon found that despite the height of the fundus 2 oz. (56 ml.) of urine could not be obtained at hourly intervals. A cystogram showed a mottled picture suggesting a large cauliflower mass arising inferiorly posteriorly in the bladder.

At operation on July 24 the bladder, which was the size of a cricket ball and had hypertrophied walls, was found to be filled with numerous rounded myxoma-like pieces of tissue varying in size from a pea to 3.5 by 2.5 by 2 cm. Some pieces appeared to be detached and floating free, others were attached by filamentous pedicles, but the most recent growth arose from a broad pedicle about the size of a postage stamp situated antero-laterally to the internal urethral meatus. Some 8 oz. (225 g.) of growth was removed and the pedicle was diathermized.

Histological examination showed that the pieces of tumour consisted of connective tissue interspersed with spindle and cylindrical cells which in many places were distinctly eosinophilic and had faint cross-striations. Some of the spindle celled areas showed a moderate number of mitotic figures. A layer of partly denuded stratified epithelium clothed the surfaces of the growth.

After operation the patient's convalescence was slow and the suprapubic wound did not heal completely. A month later he complained of pain on defaecation and micturition, and at the end of two months a polyp of growth was extruded from the suprapubic wound. On Nov. 6 the bladder was reopened and a further 8 oz. (225 g.) of growth removed. This was of the same myxomatous, avascular appearance. The pedicle had not enlarged since the previous operation and the ureters and urethra were free from invasion. The pedicle was again

diathermized. X-ray therapy was given after the operation and again in January, 1945. However, the patient's condition deteriorated, and a fistula between the bowel and the bladder formed before he died of exhaustion on Feb. 24, 1945.

At necropsy the bladder was found to be full of the proliferating growth, which had completely invaded the vesical mucosa. A fistula had formed between the ileum, bladder, and suprapubic wound. The right kidney and ureter were normal, but the left ureter was much dilated and there was an early left hydronephrosis. No secondary growths were found.

### Case II

A male child aged 9 months was admitted to hospital on Nov. 23, 1945, with a history of slight diarrhoea for one week. Two days before admission he had passed blood per rectum and since then had not micturated. He had a slight cough.

On examination he looked pale and toxic. His temperature was 100.4° F. (38° C.), pulse 142, and respirations 36. The abdomen was distended, and a cystic swelling, dull to percussion, arose out of the pelvis. Priapism was present. The external urethral meatus was slightly inflamed. On rectal examination a hard spherical tumour the size of a golf ball was found in the region of the prostate, occupying the greater part of the pelvis, with a distended bladder antero-superiorly. A provisional diagnosis of sarcoma of the prostate was made. The examining finger was blood-stained on withdrawal. Urinary examination showed a faint trace of albumin but no other abnormality. The bladder was slowly decompressed, and the following day a cystogram revealed a large bladder of good shape except for a "flattening" in the region of the trigone. On Nov. 27 intravenous pyelography did not disclose any renal or ureteral abnormality, and a skiagram of the chest was normal. The blood urea was 66 mg. per 100 ml.

The child's condition was poor from the time of admission. During the first week his temperature gradually rose to 104.8° F. (40.45° C.), his pulse to 160, and his respirations to 30. Operation was not considered feasible. On Nov. 30 his blood count was: red cells, 4,800,000 per c.mm.; haemoglobin, 47%; white cells, 21,800 (lymphocytes, 37%; monocytes, 9%; polymorphs, 4%). After decompression of the bladder he began to pass urine normally, but on Dec. 3 feeding difficulties began, and despite various changes in diet and intragastric drips the child died on Dec. 15.

Pathological findings at necropsy were limited to the urinary system. There was no evidence of metastases. The bladder was hypertrophied but small and empty. Its mucosa was congested but intact, and the ureteral and urethral lumina were freely patent. The whole organ was pushed up into the abdomen by a growth the size of a golf ball in the right lobe of the prostate. The growth appeared encapsulated and had not invaded the bladder or rectum, with which it was in contact. Hydronephrosis and hydro-ureter were absent.

Histological examination showed that the mass of growth in the prostatic region attained a diameter of 5 cm. and consisted of uniformly solid white tissue. Microscopical examination revealed cellular sarcoma consisting of large, irregular, elongated cells, the more mature of which were eosinophilic and showed distinct cross-striations in places.

### Discussion

All reported cases of rhabdomyosarcoma of the bladder and prostate have been fatal within 13 months, the average being 6½ months after the onset of symptoms. It is interesting to note that in neither of the above cases were metastases found at necropsy, despite the fact that Case I survived 11 months after the onset of symptoms. Previously reported cases also witness that metastases are uncommon, and that the usual cause of death is ascending urinary infection.

The treatment of choice would seem to be total cystectomy and prostatectomy provided that infection is controlled. Khoury and Speer (1944) carried this out; but, unfortunately, ascending urinary infection after the uretero-sigmoidostomy of the second ureter resulted in their

patient's death 2½ months after the operation. The priapism in Case II was presumably due to irritation of the nervi erigentes, as there was no oedema or cyanosis to suggest obstruction in the prostatic venous plexus caused by the expanding growth.

### Summary

One case each of rhabdomyosarcoma of the urinary bladder and of rhabdomyosarcoma of prostate are reported.

There were no metastases.

Eight ounces of growth from Case I and the internal urinary organs from Case II have been presented to the Royal College of Surgeons.

I wish to thank Mr. E. C. Bowden and Mr. J. G. Reid for permission to publish these cases, and Prof. R. A. Willis, of the Royal College of Surgeons, for the histological reports.

## Medical Memoranda

### Pure Anti-E Agglutinin in the Serum of an Rh-negative Woman

The following case is worthy of record on account of its extreme rarity. The occurrence of the agglutinin anti-E in Rh-negative women has always been complicated by coincident anti-D, in either its complete or its incomplete form, owing to the stronger affinity of the D antigen. A pure anti-E serum has been obtained in an Rh-positive woman CDe/cde—husband cDE/cde (Race, 1946). The following is believed to be the first reported instance of pure anti-E in an Rh-negative woman.

### CASE NOTES

Mrs. A., aged 26, blood group O, Rh group rr cde/cde. Husband's blood group O, Rhesus group R<sup>r</sup> cDE/cde. She had had no previous pregnancies, miscarriages, blood transfusion, or injections of serum or blood at any time. Last menstrual period, March 29, 1946; expected date of delivery, Jan. 5, 1947. She was admitted to hospital on Jan. 17 because of post-maturity.

Surgical induction (Drew-Smythe, catheter) was performed on Jan. 20, after medical induction by stilboestrol had failed. The foetal heart was last heard on Jan. 20. On the 22nd a stillborn male child weighing 9 lb. 4 oz. (4.2 kg.) was delivered after labour lasting 35 hours 15 minutes. The liquor was recorded as thick but not yellow. The skin, however, appeared slightly yellow and the umbilical cord tissue was definitely jaundiced. The placenta was large, greasy, and granular, in keeping with the post-maturity. A specimen of cord blood showed blood group O, Rh group R<sup>r</sup>: the cells also gave a strong reaction with the mother's serum. The maternal serum reacted against R<sub>2</sub> cells and R<sup>r</sup> cells, but gave negative results with R<sub>1</sub> and R<sub>3</sub> cells. The titre of the anti-E agglutinin was 1 in 8 with R<sub>1</sub> and R<sub>2</sub>R<sub>3</sub> cells.

At necropsy (Dr. Cant) the only pathological findings were the changes due to asphyxia caused by intrauterine inhalation of mucus.

### COMMENT

In addition to the production of anti-E agglutinin the actual process of iso-immunization to such a definite extent is unusual for a first pregnancy, particularly with the antigen E. Levine (1945) has shown that erythroblastosis in a first child is usually due to previous immunization by blood transfusion. Although erythroblastosis has not been implicated as a contributory cause of death, it is strongly felt that, had a living child been born, it would probably have shown the signs of erythroblastosis.

I am indebted to Dr. V. M. Cross for permission to record this case. I should like to thank Dr. Sewart for providing the case notes, and Dr. A. E. Mourant and Dr. R. R. Race for confirming the serological findings.

## Reviews

### ELECTROCARDIOGRAPHY

*Klinische Elektrokardiographie.* (Ein Lehrbuch für Ärzte und Studierende). By Max Holzmänn. (Pp. 624, with 280 illustrations and 2 coloured plates. 55 francs.) Zurich: Fretz and Wasmuth Verlag.

This important book, which was written during the later war years and published in 1945, deserves high praise. Though many textbooks of electrocardiography are available, their contents are too often merely a catalogue of electrocardiographic appearances, and seldom is any attempt made to correlate these with the facts of cardiac anatomy and pathology. This book is a welcome change.

After a brief historical survey and a short description of the apparatus available the author discusses the physiological and anatomical principles underlying the production of the normal electrocardiogram. He clearly correlates the limb-lead electrocardiogram with the vectorcardiogram and then describes fully but in simple terms the rationale of the chest and oesophageal leads. Dr. Holzmänn prefers to use the Wilson common electrode for the chest leads rather than the right arm (commonly used in Great Britain) or the left leg (U.S.A.). His account of vectorcardiography and the resolution of the potential vector (within Einthoven's triangle) is particularly well presented, as would be expected from one who has himself done fundamental work on this aspect of the subject. This method forms the only reasonable basis for an intelligent understanding of electrocardiographic appearances, both normal and abnormal. After considering variations of the normal according to body build, age, disposition of the heart within the thorax, and so on, he discusses abnormalities of conduction, heart block, and bundle-branch block. Unfortunately he is apparently unfamiliar with A. M. Master's *The Electrocardiogram and X-ray Configuration of the Heart*, for this reference does not appear among those quoted at the end of the appropriate section, though indeed this is perhaps the only reference of any importance which is not mentioned there. He continues his account of vectorcardiographic analysis in the sections on bundle-branch block and pathological ventricular hypertrophy; it is especially helpful to the consideration of cardiac infarction. In the later parts of the book he describes disorders of rhythm, including extrasystoles, auricular flutter and fibrillation, and A.-V. block. The text is clearly written throughout and the order of the sections is logical and consequential.

The book is well produced, but, as is so often the case with Continental publications, too lightly bound for use as a textbook or for reference. The references at the end of each section are not too numerous for the inquiring student and are, with few important omissions, in all cases to "key" papers on the subject under discussion. They reflect the depth of Dr. Holzmänn's learning and reading in German, English, and French. The index is adequate. The 280 illustrations portray clearly the conditions under consideration. We highly commend the book to all who wish to study electrocardiography. We hope that an English translation will be made soon.

DOUGLAS ROBERTSON.

### PNEUMOCOCCUS TYPES

*Serological Studies on the Pneumococci.* By Erna Mörch. Translated from the Danish by Hans Andersen, M.D. (Pp. 193. 10s.) Copenhagen: Einar Munksgaard. London: Geoffrey Cumberlege (Oxford University Press). 1943.

The success of the sulphonamides in the treatment of pneumonia has led, among clinicians and clinical pathologists, to a loss of interest in the type determination of pneumococci and in the use of specific anti-pneumococcal therapeutic sera. The antigenic structure of these organisms still continues to be of academic interest, however, and it is probable that this knowledge will be required for epidemiological studies of pneumonia in children and other special groups of the population.

We therefore welcome this monograph on the pneumococci, whose scope corresponds in general with that of Kauffmann's monograph on the *Salmonella* group. Though the volume con-

tains much useful information on the properties of and methods of studying pneumococci, on the formation and occurrence of pneumococcal antibodies, and on the frequency distribution of the different types of pneumococci in pathological material, bacteriologists will appreciate particularly the author's having drawn up an antigenic schema in which the types of pneumococci are grouped, numbered, and sub-lettered. Cooper and her colleagues in the United States of America were responsible for defining 32 types, Kauffmann, Mörch, and Schmith in Denmark 20 types, and now Mörch had added a further 18 types. Two of Cooper's types were found to be identical with other members of her series, so that the total known types now amount to sixty-eight. These are numbered from 1 to 42, the rest being lettered. Thus there are two types numbered 6 (6A and 6B), four numbered 7 (7, 7A, 7B, and 7C), four numbered 9 (9A, 9L, 9N, and 9V), and so on. Each type is given an antigenic formula. The number of antigens in each type varies from one to six. For example, the antigenic formulae of some of the types are as follows: Type 1: 1a; Type 6A: 6a, 6b; Type 6B: 6a, 6c; Type 7C: 7a, 7d, 7f, 7g, 7h; Type 42: 42a, 20b, 29c, 33g, 35c, 35d. From these formulae it can be seen whether crossing is likely to occur between different types when tested by agglutination. Finally the author describes each type and gives evidence to prove its right to specific recognition. More types of pneumococci may be recognized in future; if so, it should not be difficult to fit them into the present framework.

G. S. WILSON.

### TEXTBOOK OF EMBRYOLOGY

*Human Embryology.* By Bradley M. Patten. Professor of Anatomy in the University of Michigan Medical School. (Pp. 776; 1,366 illustrations, 53 in colour. 45s.) London: J. and A. Churchill Ltd. 1946.

Descriptive embryology still occupies the greater part of most textbooks of human embryology, with certain notable exceptions, of which this book is not one. The wide fields of embryological research opened up in the last few decades—especially that of developmental mechanics—usually receive little attention, presumably because such work, though it affords a wider view of the nature of human developmental processes, has been done mainly on non-human forms. Inclusion of the principal results of this work would have greatly added to the value of the book. Moreover, we should like to find the post-natal developmental processes discussed within a single volume as a continuation of the antenatal phases.

This textbook for medical students, though bulky, is of restricted scope; it is noteworthy for the clearness of its illustrations, most of them either new or redrawn. Prof. Patten surveys the sexual cycle and earliest developmental stages with reference to recent work both in man and in related forms, and he draws attention to a few of the measurements which have been made on growth changes; but the accounts and figures of chromosomes and mitosis are out of date and inaccurate. He tries to provide elementary answers to some of the questions so often asked on such subjects as the "safe period," superfetation, and the origin of "congenital" abnormalities. We should have liked to see fuller statements on these matters and some reference to related topics such as freemartins and intersex conditions. He almost completely ignores the problems of developmental mechanics and the results obtained from experimental embryology; we find no mention of metaplasia—the progressive modification of cell potentialities—of dependent differentiation, of mosaic patterns, or of induction. He does not discuss the manner in which the pattern of peripheral nerve distribution is established, and he leads us to believe that the simple intrasegmental reflex is the basic vertebrate pattern, without mentioning its progressive differentiation from the generalized reflex described by Coghill. It is surprising to find a descriptive account of the cranial nerves that refers almost solely to the adult and seems out of place in a textbook of embryology. The accounts are in any case inaccurate—e.g., the sino-carotid component of the ninth nerve is ignored, while he claims that a cutaneous component is present. The account of bone development is elaborate but leaves obscure the part played by "fibrous" ("wavy") bone. He mentions the use of alizarin dyes for the study of bone growth, but does not show how it elucidates the remodelling of bones. Again, it is

incorrect to describe cartilage as avascular until ossification is impending; there is no mention of the vascular "cartilage canals."

It is to be regretted that he gives no guidance to certain much discussed questions—for instance, the relation of heredity to environment, the so-called "recapitulation," and human hybridization. Current views on such problems are intimately connected with our knowledge of developmental mechanisms, and they should be expounded in a student's textbook. The author treats his subject unevenly, some parts being so full as to be suited only to the teacher while others are presented in so popular a fashion as to be less suited to medical students than to the laity. The long bibliography containing some thousand references omits some of the newer contributions (e.g., by Needham) in favour of older ones. There is no guidance for the student on how to read selectively nor is he shown how the text is related to the references.

If we have stressed the omissions in this book it is because they will disappoint the senior student, while the junior will not find the guidance that he requires. In contrast, however, the descriptions of organogeny, which have constituted so much of the conventional field of embryology in the past, are well set out and made clear with the aid of excellent pictures. As a work of reference this book will be useful on the shelves of every anatomical library.

ARTHUR B. APPLETON.

### TORULOSIS

*Human Torulosis (A Clinical, Pathological and Microbiological Study, with a report of thirteen cases).* By Leonard B. Cox, M.D., M.R.C.P., F.R.A.C.P., and Jean C. Tolhurst, M.Sc. (Pp. 149; 67 figures. 25s.) Melbourne: Melbourne University Press. 1946. London: Geoffrey Cumberlege (Oxford University Press).

Torulosis, although widely distributed, is believed to be uncommon in all countries, but its rarity is difficult to estimate because accounts of many diagnosed cases have not been published, and, presumably, many more cases not correctly diagnosed are included in the returns of tuberculosis and similar diseases. The greatest number of cases have been reported in the U.S.A., but the highest incidence of the disease in proportion to population appears in Australia.

This admirable work is the latest and most comprehensive monograph on torulosis. The authors present, among other features, a valuable historical record of the disease, followed by a detailed clinical and pathological study of thirteen hitherto unpublished records of Australian cases, and a clinical analysis of the disease in relation to particular systems and organs, with differential diagnosis. They clearly describe the pathology and morbid histology in man and in experimentally infected animals, and include 67 excellent photographs. Although any tissue or organ may be involved, torulosis affects chiefly the central nervous system and its meninges and the lung; it may simulate intracranial tuberculosis, neoplasm, or abscess; and a particular form may be almost indistinguishable from Hodgkin's disease. The diagnosis, therefore, necessarily depends on the mycological examination, a subject to which the authors have given particular attention. They describe the characters and identification of the causative fungus, *Torula histolytica* Stoddard Cutler 1916 (*Cryptococcus neoformans* (Sanfelice 1895) Vuillemin 1901), and, in an illuminating discussion on the mode of infection in torulosis, conclude that *T. histolytica* probably gains entry through the lung and is dispersed by way of the blood stream. Treatment of the intracranial infection is disappointing and the disease is almost inevitably fatal. A bibliography of 134 titles and an adequate index complete this work, which will prove valuable to mycologists and to all practitioners of medicine, especially those who have not yet learned to appreciate the importance of the grave systemic mycoses.

J. T. DUNCAN.

A third edition of *Dental Materia Medica, Pharmacology and Therapeutics*, by Prof. WALTER J. DILLING and Mr. SAMUEL HALLAM, has been published by Cassell and Co., at 13s. 6d. The arrangement of this manual is as before, but new accounts are given of a number of drugs, and the text has been revised to keep pace with recent advances, both scientific and clinical. The names of the drugs are those officially adopted by the British Pharmacopoeia Commission, but well-known proprietary names are quoted as synonyms.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Mongolism and Cretinism.* By Clemens E. Benda, M.D. (Pp. 310. 25s.) London: William Heinemann. 1947.

A study of mongolism as a pituitary dysfunction and an account of cretinism.

*Psychology of Women, Vol. II, Motherhood.* By Helene Deutsch, M.D. (Pp. 439. 25s.) London: Research Books. 1947.

A psycho-analytical interpretation of motherhood.

*Essentials of Syphilology.* By Rudolph H. Kampmeier, A.B., M.D. 2nd ed. (Pp. 465. 25s.) Oxford: Blackwell Scientific Publications. 1946.

A textbook on syphilis for the medical practitioner, with many illustrations.

*Diagnostik der Kinderkrankheiten.* By Prof. Dr. E. Feer. 5th ed. (Pp. 428. 32s.) Vienna: Springer-Verlag. London: H. K. Lewis. 1947.

The differential diagnosis of children's diseases for students and practitioners; many illustrations.

*The Psycho-Analytical Approach to Juvenile Delinquency.* By Kate Friedlander, M.D., D.P.M. (Pp. 296. 18s.) London: Kegan Paul, Trench, Trubner and Co. 1947.

Discusses juvenile delinquency, its background and treatment, the training of field workers, and prevention.

*Applications of Germicidal Erythral and Infrared Energy.* By Matthew Luckiesh, D.Sc., D.E. (Pp. 463. 30s.) New York: D. Van Nostrand Company. 1946.

Discusses the use of radiant energy for disinfection, its artificial production, and its effect on the human body, textiles, and plants.

*A Textbook of Gynaecology.* By James Young, D.S.O., M.D., F.R.C.S.Ed., F.R.C.O.G. 7th ed. revised. (Pp. 471. 30s.) London: Adam and Charles Black. 1947.

Incorporates recent advances in endocrinology and new material on ovarian tumours; 17 new illustrations.

*Handbook of Preventive Medicine.* By the Air Ministry. (Pp. 213. 7s. 6d.) London: His Majesty's Stationery Office. 1947.

Information on hygiene, sanitation, communicable diseases, nutrition, etc., for the R.A.F.

*The Road to Maturity.* Ed. by Edward F. Griffith, M.R.C.S., L.R.C.P. (Pp. 232. 7s. 6d.) London: Methuen. 1947.

Essays on sex education by various authors.

*Tubercules Inapparentes.* By Prof. Ch. Dejean. (Pp. 191. 250 francs.) Paris: Librairie Maloine. 1946.

An account of atypical or latent tuberculous conditions, their pathology, diagnosis, and treatment.

*Eléments de Physiologie Humaine.* By Prof. L. Launoy. 2nd ed. (Pp. 760. Papcr, 150 francs; bound, 350 francs.) Paris: Librairie Maloine. 1947.

A textbook of human physiology for students.

*Chemical Anatomy, Physiology and Pathology of Extracellular Fluid.* By James L. Gamble. 5th ed. (7s. 6d.) Harvard University Press. (London: Geoffrey Cumberlege.) 1947.

A summarized lecture syllabus for teaching purposes; with diagrams and references.

*The Sanitary Inspector's Handbook.* By Henry H. Clay, F.R.San.I., F.I.S.E. 6th ed. (Pp. 545. 22s.) London: H. K. Lewis. 1947.

The methods and apparatus of hygiene and sanitation, with reference to the relevant laws.

*Insect Pests.* By W. Clunie Harvey, M.D., D.P.H., M.R.San.I., and Harry Hill, F.R.San.I., F.S.I.A., A.M.I.S.E. 2nd ed. (Pp. 347. 14s.) London: H. K. Lewis. 1947.

Two new chapters have been added on mosquitoes and moths and on D.D.T.

*Molecules Against Microbes.* By E. S. Duthie, M.B., Ph.D. (Pp. 150. 6s.) London: Sigma Books. 1946.

An account of chemotherapeutics and antibiotics for the layman.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 19 1947

## NEXT WEEK'S A.R.M.

The Representative Body will hold its annual meeting at B.M.A. House on Tuesday next week and succeeding days. Next year the usual peacetime Annual Meeting of the Association will take place in Cambridge. It was at Cambridge that the first normal peacetime meeting was held after the war of 1914-18. The London meeting next week is the last A.R.M. to be held before the appointed day of the National Health Service Act—July 5, 1948. Special Representative Meetings will of course be held before that day. The *Supplements* to the *Journal* of July 12 and 19 contained the resolutions submitted by Divisions and Branches, which have drawn these up in the light of the Annual Report of Council which appeared in the *Supplement* of April 26. Some of these resolutions bear upon the National Health Service Act and many of them upon the usual professional issues that arise out of the year's work of the various committees of the Council.

The present moment might be described as a period of remission in the medico-political fever to which the corporate body of medicine has been subjected during the past two years. That the present quiet phase may disturb many medical men is natural. It is, however, inevitable, because the discussions of the Negotiating Committee and its numerous subcommittees with the Ministry of Health have quite properly taken place in the seclusion of the conference room. No one can have been impressed by the results of the open diplomacy practised on the public platforms of international politics. The dangers are no less in the smaller sphere of medicine. A blaze of publicity sometimes has an unfortunate effect on debaters and encourages them to gain cheap verbal victories instead of talking to the point. The medical profession should therefore, we suggest, have the patience to trust those whom it has appointed to negotiate on its behalf and to wait until the results of its discussions with the Ministry and its final discussion with the Minister have been made public. Democracy, as someone has said, is discussion, and it has often been held that the cardinal political virtue of this country is the ability to arrive at compromise as a result of such discussion. Whether or not the Minister of Health will practise this political virtue when he comes to arbitrate on matters which the profession holds to be fundamental remains to be seen. If we are to achieve what both the medical profession and the Minister desire—namely, the best comprehensive medical service for the people of this country—there must be give and take on both sides. But if there is a clash on fundamental principles the medical profession will not hesitate to stand firm. And the one principle that underlies all others is the right of the

individual to preserve his freedom of thought and action in a democracy based upon the Rule of Law and the Sovereignty of Parliament.

Newcastle-upon-Tyne is next week moving that the Negotiating Committee be asked to make an early report of the progress and discussions with the Minister. Without prejudicing the discussion this would seem to us to be a motion which attempts to push wider the already wide-open door. It can be in the interests of no one to withhold a report. Marylebone dots the i's and crosses the t's of the Council's statement on the results of the plebiscite; Bath considers that when a further plebiscite is taken the B.M.A. Council should "give a strong lead to the profession in the light of the findings of the Special Representative Meeting"; Buckinghamshire considers that before any future plebiscite there should be a clear exposition of the Association's policy but that the actual voting paper should be sent under separate cover and unaccompanied by any expression of opinion; Buckinghamshire also moves that the result of a future plebiscite should be binding on the Council. To arrive at decisions by the method of plebiscite is notoriously difficult, especially when the questionnaire is addressed to matters of opinion. It is difficult enough even when a questionnaire is restricted to matters of fact, as is well exemplified by the familiar problem facing the man asked to say Yes or No to the question "Have you stopped beating your wife?" Even a questionnaire worded in the most careful manner possible presents a thorny problem to those who have to base action on the result. The guidance of a statistician is necessary to make it clear whether an apparent majority is a real majority. And if there is a real majority, at what point does it become large enough to convince the minority that they should accept the verdict of their fellow voters? Whatever the results of another plebiscite may be, the Council of the B.M.A. may find itself pressed on by those whose feelings will prompt them to interpret the figures in a way favourable to their own point of view. Whatever the Council may decide, it will court unpopularity with those who wish to decide otherwise. In any event, the Council will have a hard task, and its success in grappling with it will be measured by the degree of objectivity it brings to bear on its examination. Credited with the objective approach it has tried to make to all professional problems, and which it will undoubtedly make to those facing the profession in the immediate future, the Council should be able to count upon the trust and loyalty of the members of the Association. Given a sufficient majority—the size possibly stated before the plebiscite—the Council should also be able to count on the loyal support of the minority in the action the majority wish to take.

If we keep our heads cool and our feet warm we shall be able to preserve those essential qualities which distinguish a profession from a trade and also from an applied science. The best minds in medicine are fully conscious of the continuity of medical history and of the fact that each succeeding generation of doctors inherits the best traditions of the past. So long as this continuity is uninterrupted by revolutionary methods forcibly introduced detail of service and administration will fit into place.

## CHROMATOGRAPHY APPLIED TO MEDICINE

Chromatography is a relatively new technique of qualitative, and to some extent quantitative, chemical analysis. Having already established itself, somewhat belatedly as it appears, in biochemical research, it is now beginning to invade hospital practice. In the words<sup>1</sup> of the President of the Royal Society, it foreshadows "a leap forward in our knowledge of the proteins."

Like many other innovations in technique chromatography began slowly. It was as long ago as 1905 that the Russian botanist Tswett published his first paper<sup>2</sup> on the separation of organic substances by the use of an adsorption technique which was his own invention. Whereas others had been content to shake their adsorbent material with the fluid from which adsorption was to be effected, the procedure followed by Tswett was to allow his solution to flow slowly downwards through a glass tube containing the adsorbent material. Working with the yellow and green pigments of plants, he found that a succession of coloured bands was formed in the adsorbing column, which could be brought out and "developed" by the further passage through the column of the pure solvent. In this way he was able to effect mechanical separation of the pigments under investigation. Unfortunately, however, the bulk of his work was published only in Russian; and partly for this reason, and partly also, no doubt, because the separation and identification of small amounts of naturally occurring substances attracted less attention then than now, little interest was aroused at the time. In fact, twenty-five years were to pass before Kuhn, Winterstein, and Lederer<sup>3, 4</sup> effectively revived his method in Germany for the study of carotenoid substances.

Subsequent extensions to Tswett's original technique include its adaptation to colourless substances through such devices as the use of ultra-violet radiation to show up stratification bands on the adsorbent column; "liquid chromatography," in which successive bands are washed or "eluted" through the column by the use of further quantities either of the original solvent or of others; and, finally, two more radically new developments, both of which are due to a research team at the Wool Industries Research Association laboratories at Leeds. It may be mentioned in passing, however, that it was by the use, substantially, of Tswett's adsorption method that Binkley, MacCorquodale, Thayer, and Doisy<sup>5</sup> were able in 1939 to extract pure vitamin K from crude alfalfa, containing less than one part in two thousand of the vitamin, no other method of separation but successive chromatographic adsorptions being employed.

The first of the Leeds innovations consisted in the replacement of the original adsorption column by a column filled with silica powder which had been allowed to absorb water but not to a sufficient extent to become wet in the ordinary sense. As before, a succession of bands is formed in the column as the material under examination passes through it; but the effect is due not to adsorption but

to the partition of the various substances between two liquid phases—the original solution, and the silica gel of the particles which make up the column. For this reason the method is known as "partition chromatography."<sup>6</sup> It was developed by Martin and Synge at Leeds for the study of the amino-acids of wool, but among many later uses has had a share in the isolation of pure synthetic penicillins by Du Vigneau and others.<sup>7</sup> This technique has been in turn transformed, for use on a micro-scale, by the substitution of so simple a material as a strip or sheet of filter paper for the silica column. It was of this latter method, which is due to Consden, Gordon, and Martin,<sup>8</sup> that Robinson in the reference already quoted stated: "I gather the chief requirements are a lead tray, an earthenware drainpipe, and a piece of paper." It has proved itself equally well adapted to the requirements of research and of routine measurement and has already been used<sup>9</sup> for such varied purposes as the elucidation of the structure of gramicidin-S by the Leeds team, the routine analysis of penicillin mixtures,<sup>10</sup> and by Dent for the examination of amino-acids in urine.<sup>11, 12</sup> Still more lately a first attempt has been made by La Cour and Drew to apply the method in cytology.<sup>13</sup> Its power is shown by the fact that in its original use 0.002 grammes of wool sufficed for the demonstration of all the amino-acids whose presence could be shown by other methods.

In the simple strip method partition is between water and any suitable organic solvent, and the material under examination is separated in a series of bands running transversely across the strip. In the case of the amino-acids ninhydrin has been employed as the colour reagent. Should separation in any case be incomplete, all that is necessary is to repeat the analysis with the use of a sheet instead of a strip of filter paper; and, with a different solvent, to carry through a second separation in a direction at right angles to the first. The various amino-acids then appear like so many rough two-dimensional plots on a sheet of graph paper, and can be physically separated by a pair of scissors.

It is a remarkable fact that, even if no other evidence had been forthcoming, the application of this filter-paper technique would alone have sufficed to demonstrate not only that gramicidin-S is a cyclopeptide—that is, a ring structure composed of successive amino-acids—but also to specify the order in which the different amino-acids concerned appeared in the ring. This was achieved by examination of the partial hydrolysis products, consisting of either two or three amino-acids in combination, and the subsequent breakdown of these di- and tri-peptides into their constituent amino-acids. Filter-paper technique was used at all stages, and each of the five linkages of the cyclic structure directly demonstrated.

Clinically, the method has been used to show abnormalities in the amino-acid content of the urine in cases of subacute hepatic necrosis, Fanconi syndrome, and in late pregnancy. From this it would be a natural next step to study the elimination of amino-acids administered by the

mouth in known amounts, and to compare the patterns obtained from normal patients with those in pathological cases. In principle, therefore, the method would appear to offer the possibility of a diagnostic test of unusual subtlety. Since, in addition, it can be applied to the separation of any substances which have a suitable partition coefficient between water and any organic solvent, the possibilities for clinical research must be considerable.

Although each of the chromatographic methods which have been mentioned is intrinsically capable of medical application, it may be expected that the filter-paper technique will make the widest appeal. Three books covering the whole or part of the subject are available.<sup>14-16</sup> Of these, Bacharach and Robinson's is a translation of the original German classic and contains full references up to 1938, and Williams's with select references up to 1944 is both the most recent and the best fitted to serve as a general introduction.

### DFP IN GLAUCOMA

Although war gases are regarded by most people with more abhorrence than guns or bombs they are in fact more readily converted to the uses of peace. Several of the new gases discovered during the war are already proving to be useful tools in the advance of medical knowledge, and a few of them may even become valuable agents of healing. Diisopropyl fluorophosphonate, or DFP, is an excellent example of this modern version of swords beaten into ploughshares: the recent work of Leopold and Comroe<sup>17</sup> at Philadelphia suggests that this highly toxic substance may prove to be of great value in the treatment of glaucoma.

The powerful physiological effects of fluorophosphonic esters were first observed by Lange and Kreuger,<sup>18</sup> who prepared the dimethyl and diethyl esters in 1932; indeed, it was the observation by these authors of marked effects upon respiration and the eyes after brief inhalation of the vapour of these esters which led a group of Cambridge workers to re-examine the alkyl fluorophosphonates in the early years of the war. The most conspicuous effect of inhalation of fluorophosphonic esters is a long-lasting miosis, accompanied by spasm of accommodation, and, Adrian, Feldberg, and Kilby<sup>19</sup> discovered in 1941 that these eserine-like effects were due to an intense inhibition of cholinesterase. This inhibition was found by Dixon and his colleagues<sup>20</sup> to be, unlike that produced by eserine, progressive and irreversible, an observation which explains the prolonged character of the physiological effects. In 1941 McCombie and Saunders<sup>21</sup> prepared a series of homologous esters, of which the diisopropyl ester was found by Adrian and his colleagues to be the most potent.

Aqueous solutions of DFP are not stable, but Leopold and Comroe report that 0.1% solutions in peanut oil retain their potency for several months. In the normal eye instillation of such solutions produces prolonged and intense miosis, spasm of the ciliary muscle, false myopia, and decreased intraocular tension; these effects are equal to or greater than those reported for 1% eserine or 5% "prostigmin." Moreover, 0.2% DFP will overcome the effects of 1% atropine.

In the glaucomatous eye 0.05–0.1% DFP in peanut oil successfully lowers intraocular tension in a higher proportion of patients and with decidedly fewer instillations than either pilocarpine or eserine. Leopold and Comroe found it effective in controlling intraocular tension in 43 of 48 eyes with chronic simple glaucoma, when pilocarpine or eserine was effective in only 21 eyes. Similarly DFP was much more effective than pilocarpine or eserine in eyes in which glaucoma developed after cataract extraction.

Repeated doses of DFP produce a slight decrease in plasma cholinesterase but no systemic symptoms. The drug does, however, have some untoward and undesirable effects—namely, visual blurring, brow and eye ache, spasm of accommodation, and periorbital injection. These effects are not troublesome in all patients and, in particular, are not prominent in patients with glaucomatous aphakic eyes. In spite of these defects the authors regard DFP as a promising alternative to eserine; it is certainly very effective, and it requires much less frequent application. They were unable to recommend any particular dosage regime; the frequency of application must be determined by repeated checks of the intraocular tension. In their experience administration may be required only once daily, or even once weekly.

The results of Leopold and Comroe have been largely confirmed by McDonald<sup>22</sup> in a series of careful clinical studies and by Lebensohn<sup>23</sup> in a smaller number of patients.

### OPERATION FOR CONGENITAL PULMONARY STENOSIS

Surgery has been successfully applied to most of the viscera, but surgery of the heart has been relatively slow to develop. The surgery of congenital heart disease, until recently a sterile field, now offers hope of relief to many sufferers owing to the brilliant work of several surgeons. Maude Abbott, in her classical *Atlas of Congenital Cardiac Disease*, suggests a clinical classification of three groups of cases. In Group 1 she places those cases with no abnormal communication (acyanotic group); a representative of this group is co-arcuation of the aorta, which can now be relieved by the brilliant operation of Crafoord's.<sup>24</sup> Group 2 includes cases of arterial-venous shunt with terminal reversal of flow (cyanose tardive); patent ductus arteriosus is representative and its relief by ligation is now almost a standard procedure. Group 3 comprises cases of permanent venous-arterial shunt and retardation of flow (cyanotic group), and surgery can now give relief to patients in this last group.

In 1945 Blalock and Taussig<sup>25</sup> described attempts to relieve certain cases of congenital heart disease in which pulmonary stenosis or pulmonary atresia exists by performing an anastomosis between a systemic artery and the right or left pulmonary artery. The argument behind this operation was that one cause for the cyanosis is the delivery of an inadequate quantity of blood to the lungs. The systemic artery used has been either the innominate or the subclavian or even the carotid. Within two years of the first paper recording 3 cases Prof. Blalock<sup>26</sup> has been able, in the first Edward Churehill lecture, to record his results in operations upon 243 patients; the overall mortality was 21%, though in the second hundred it was only 15%. Blalock considers that in patients between the ages of 2 and 12 years in whom a typical tetralogy of Fallot is present with a small heart the operative risk should be less than

<sup>26</sup> *Ann. Surg.*, 1947, 125, 129.

12%. When atypical conditions exist such as a large heart, situs inversus, large aorta, the danger of the operation increases. The age of his patients has ranged from 4 months to 26 years, but the best period is from 3-10 years. The mortality is higher in infants under 2 years, and operation is not advised under 18 months unless the chances of survival to an older age are less than 50%. In older patients it is more difficult to bridge the gap to the pulmonary artery with the systemic artery, and the structures are less elastic and pliable. It is significant of the gravity of the condition that 20 patients have died while awaiting admission to hospital.

In 147 patients in whom the subclavian artery was used the mortality was 9%; in 57 in whom the carotid or innominate was used the mortality was 33%. Blalock now feels that the extra size of the innominate artery is probably rarely necessary to secure the highest rise in oxygen saturation, as it is probably more than balanced by the extra strain on the heart. The much higher mortality would certainly appear to be pertinent. Blalock's intermediate papers<sup>22</sup> should also be consulted for valuable information. The results of the operation have been, in general, very gratifying. Cyanosis is relieved almost at once; the arterial oxygen saturation may improve from 30% to 80%; children who could walk only a few feet before operation are enabled to walk a mile or more and some can engage in fairly strenuous exercise.

The Blalock-Taussig operation is ingeniously conceived and has given great relief to many patients, but it is still too early to assess the results fully, for the operation, by creating an artificial ductus arteriosus, exposes the patient to the later risks of cardiac failure or infective endocarditis. As the authors themselves say, however, it is better to run these risks in later years than to suffer and die from anoxaemia and cyanosis in the present. Recently Potts, Smith, and Gibbons<sup>23</sup> have described a method of direct anastomosis of the aorta to the pulmonary artery as an alternative to Blalock's operation.

The surgical treatment of congenital pulmonary stenosis is to be discussed at the International Congress of Surgery in London in September and the opener will be Prof. Blalock.

### HIGH-VOLTAGE X RAYS

In a recent leading article<sup>24</sup> on the generation and properties of high-voltage x rays, we suggested as the next step that equipment similar to the 30 million-volt synchrotron, now approaching completion at the Telecommunications Research Establishment of the Ministry of Supply, should be given therapeutic trial at a limited number of centres. This view has now been endorsed by the decision of the Medical Research Council to order two further such synchrotrons for medical use. They have been allocated to Cambridge and the Royal Cancer Hospital, where Prof. J. S. Mitchell and Prof. W. V. Mayneord respectively can be relied upon to secure the fullest information from them. Apart from the obvious, and indeed dramatic, interest of an approximately tenfold increase in x-ray voltages, a thorough examination of both physical and therapeutic effects is needed for future policy. No changes in methods of generation can render such data obsolete, for the physical properties of x rays are determined by voltage alone; and, even with existing methods, it is probable that appreciably higher voltages could be produced. It may therefore be necessary to decide how far up in voltage it is

worth while to go. The immediate prospect is for a depth dosage at five centimetres equal to about four times that at the surface.

### ACQUIRED RESISTANCE TO PENICILLIN

One of the chief reasons why penicillin treatment should be aided so far as possible by laboratory control is that susceptibility to penicillin varies not only among bacterial species but sometimes among strains of the same species. When abnormal resistance is exhibited by an individual strain, it may be either natural or acquired by habituation. The capacity of different strains to develop resistance by habituation varies. Very fortunately, resistant strains of Group A *Str. pyogenes* are never encountered, nor can this organism be induced by the usual proceedings to develop anything more than a slight increase of resistance *in vitro*. *Staph. aureus* goes to the other extreme: resistant strains are being encountered with apparently increasing frequency, and *in vitro* resistance can be artificially increased by as much as 5,000-fold. The peculiar interest of the behaviour of staphylococci is that resistance developed *in vivo* and *in vitro* differs in nature; the former is unaccompanied by any change in cultural characters, is permanent, and is due to the production of penicillinase: while the latter is accompanied by a change in colony type, is rapidly lost on transfer to normal media, and is not due to penicillinase formation. Why two evidently different mechanisms should operate under different conditions to produce a similar effect is still unexplained. It is also by no means certain whether the underlying process is one of selection or adaptation. K. R. Eriksen<sup>1</sup> takes the former view, basing it on the proportion of abnormal colonies found on plating broth cultures undergoing habituation or subsequent to the release from the influence of penicillin. He also observed actual stimulation by penicillin of the growth of a resistant strain, which recalls J. Ungar and P. Muggleton's<sup>2</sup> finding that penicillin in concentrations of 1 or 5 units per ml. stimulates the growth of tubercle bacilli. E. P. Abraham, D. Callow, and K. Gilliver,<sup>3</sup> on the other hand, take the view that modification and not selection is the basis of acquired resistance to antibiotics in general: they employed three, none of which was actually penicillin, and found that after habituation to one of them *Staph. aureus* adapted itself in the same way to another, which is not to be expected if the former process eliminated all but the descendants of a few originally resistant cells. F. H. Stewart,<sup>4</sup> working with sulphonamides and *Shig. flexneri*, also concludes that adaptation accounts for acquired resistance to these drugs.

Of much more practical importance is the mode of origin of resistant strains found in patients. E. A. North and R. Christie<sup>5</sup> have studied this question intensively in the ward of a plastic surgery unit where many resistant strains of *Staph. aureus* were encountered. Regular specimens were taken, and all coagulase-positive strains subjected to biochemical and serological examination as well as tests for susceptibility to penicillin. An interesting fact is that resistant strains appeared mainly in wounds of such a nature that treatment with penicillin was unlikely to be fully effective. These authors give reasons for rejecting the very plausible hypothesis that the appearance of resistant strains was due to cross-infection, nor do they believe that selection accounted for it. Reasons for the latter view are that resistant strains were never encountered before treatment, and that a mixture of sensitive and resistant colonies was never obtained. They incline, there-

fore, to the adaptation hypothesis, suggesting that "the stimulation by penicillin to change potential penicillinase-producing staphylococci into actual penicillinase-producing variants offers the most satisfactory explanation."

The organism which has been most anxiously watched from this point of view is the gonococcus, and so far no unequivocal evidence that it can become seriously penicillin-resistant has yet been forthcoming. It is therefore somewhat alarming to read that C. Huriez and M. Desurmont,<sup>6</sup> of Lille, believe they have observed the "beginnings of penicillin-resistance" in gonorrhoea. Since the "liberalization" of penicillin (to what degree of freedom of use this refers is not clear) the number of cases coming to their clinic has diminished, and there have been patients requiring very large doses—as much as 4,400,000 units in all—together with sulphonamide treatment and artificial fever, before cure was effected. This is certainly a tendency which, if verified and maintained, will call for rigorous measures of control.

### BLINDNESS IN SCOTLAND

A statistical survey of 3,219 blind persons in Glasgow and south-west Scotland was undertaken in 1942 by Marshall and Seiler.<sup>7</sup> Dickson<sup>8</sup> has now studied 4,078 certified cases in other parts of Scotland. The sexes were equally represented in the records studied by Dickson, and the group aged 65 or over contributed the largest number of cases—1,612; the age group 50–64 came next with 1,307. In the 40–49 group there were 443 cases, and there were progressively fewer in the younger groups. Thus there were only 33 cases in the age group 1–4, and none under 1 year. The causes of blindness were: cataract in 17.3% of the patients, myopia (13.8%), venereal disease (12.8%), chronic septicaemia (10.9%), glaucoma (7.6%), and injury (4.0%).

The individual causes of blindness varied in the different age groups. Where the onset of blindness was in the pre-school period (0–4 years) Dickson found that congenital anomalies and ophthalmia neonatorum were together responsible for 62.8% of the total of 366 cases; congenital syphilis was the cause in only 8.4% of these cases. With onset in the school period (5–15 years), however, the commonest cause of blindness was congenital syphilis, accounting for 22.6%; congenital anomalies and abiotrophies came next and were responsible for 19%. The causes of blindness with onset in the adolescent period (16–29 years) were: congenital anomalies (20%), congenital syphilis (13.2%), chronic septicaemia (12.2%), trauma (11.7%), and myopia (11%). Onset during the working period (30–49 years) followed myopia in 16.7% of cases. Other causes were chronic septicaemia (15.1%), abiotrophies (9.2%), acquired (8.1%) and congenital (7.4%) syphilis, and trauma (7.1%), including sympathetic ophthalmia. Over the age of 50 cataract (29.1%) was the most usual cause, and then myopia (16.3%), glaucoma (12%), chronic septicaemia (10.5%), and vascular diseases (6.6%).

On the basis of actual duration of blindness in "patient years" the more important causes were a miscellaneous group. Chronic septicaemia came first with 12.3% of all the "patient years" of blindness; congenital syphilis, congenital anomalies, and ophthalmia neonatorum were almost as significant. Next in importance were injury and myopia, and then cataract, local infections, and abiotrophy. Glaucoma, acquired syphilis, and phlyctenular disease were each the cause of about 3% of the total of "patient years" of blindness. In about 13% of the cases some improvement by treatment seemed likely. But the regional survey indi-

cated that, for example, in the Inverness and Zetland regions the importance of cataract as a cause of blindness was at least partly due to lack of facilities for operative treatment in the sparsely populated country areas. In Dundee myopia was particularly common, while in Aberdeen retinitis pigmentosa was relatively prevalent.

Dickson's report agrees closely with that of Marshall and Seiler, and he gives consolidated tables for the two investigations. The causes of blindness in Scotland are not dissimilar from the causes observed in England and Wales as recorded by Sorsby,<sup>9</sup> except that the Scottish figures show a distinctly greater incidence of infections. These differences may be adventitious, owing to individual and local variations in registration, but Dickson's plea for more precise statistics is sound. There is much to be said for his advocacy of annual publication of authoritative statistics of blindness.

### HUMAN NUTRITION LABORATORY AT OXFORD

The Trustees of the Will of the late Sir Henry Wellcome have offered Oxford University up to £25,000 to buy suitable premises for a Wellcome Laboratory of Human Nutrition. This handsome gift of money will also be used to alter and equip the premises adequately as a centre for fundamental research on human nutrition. The Wellcome Trustees have made this gift on condition that the University will provide an annual sum of £5,000 for the maintenance of the laboratory for a period of at least five years from the date that it becomes available for occupation. Another proviso is that if the laboratory ceases to be used for its initial purpose the house and its equipment, or its realized value, will be applied by the University for research "within the wide range of the sciences contributory to medicine and to the physical well-being of men and animals." The University has gratefully accepted the gift and has decreed that such a laboratory shall be instituted for the conduct of fundamental research into the problem of human nutrition which have their origin in physiology, biochemistry, pathology, anthropology, or clinical science. Field research may be undertaken either in this country or abroad. The management of the laboratory will be in the hands of a standing committee of two members appointed by the Board of the Faculty of Medicine, two appointed by the Board of the Faculty of Biological Sciences, and the Reader in Human Nutrition, who will act as secretary of the committee. The committee may decide to transfer to the laboratory some of the apparatus and equipment formerly belonging to the Oxford Nutrition Survey. This handsome gift of the Wellcome Trustees will enable Oxford to follow the example already set by Cambridge.

### THE HALF-YEARLY INDEXES

The half-yearly indexes to Vol. II of the *Journal* and the *Supplement* for 1946 have been printed. They will, however, not be issued with all copies of the *Journal* but only to those readers who ask for them. Any member or subscriber who wishes to have one or both of the indexes post free, should send a postcard to the Accountant B.M.A. House, Tavistock Square, London, W.C.1. Those wishing to receive the indexes regularly should intimate this.

On July 10 Sir Alfred Webb-Johnson, Bt., was re-elected President of the Royal College of Surgeons of England for the seventh successive year. This is a record. Lord Moynihan held the office for six years from 1926 to 1931, and Sir William MacCormac for five years from 1896 to 1900.

<sup>6</sup> *Presse méd.*, 1947, 2, 13.  
<sup>7</sup> *Brit. J. Ophthalmol.*, 1942, 25, 337.  
<sup>8</sup> *Ibid.*, 1946, 26, 281.

## TUBERCULOSIS AND THE HEALTH ACT

MR. ANEURIN BEVAN AT ANTI-TUBERCULOSIS  
CONFERENCE

A Commonwealth and Empire Health and Tuberculosis Conference, arranged by the National Association for the Prevention of Tuberculosis, was held in London from July 8 to 10. It was attended by delegates from over thirty Dominions and Colonies and nearly twenty foreign countries. Government departments, local authorities, voluntary organizations, and industrial and commercial concerns were represented, the last-named not only by their medical and welfare officers, but by their executives, personnel managers, and trade union officials. Sir Robert Young was chairman of the Conference, and the Duchess of Kent, president of the National Association, welcomed the members.

Mr. Aneurin Bevan, Minister of Health, attended a session at which the discussion was on the National Health Service Act and its effect on tuberculosis work. He said that after a setback during the earlier part of the war the tuberculosis mortality rate was again declining, and although notifications were increasing in number this was due only to the greater accuracy in diagnosis and to earlier discovery. Mr. Bevan went on to say that he had inherited "a very considerable apparatus" in the shape of sanatoriums and specialist staff. "I do not propose so much to change what exists as to continue, amplify, and improve it."

## Not a "Soulless Affair"

There were sceptics who talked as if the health service of the future was going to be a centralized, State-run, soulless affair in which human personality would not be able to find expression. That was the very opposite of what was proposed. He wanted each sanatorium to maintain its identity and continue to be run under its separate name. Although the sanatoriums and dispensaries would be made an integrated part of the health service as a whole, the institutions would be maintained on as independent and voluntary a basis as possible.

"In this health service we are making a big experiment which, if it succeeds, is going to be very important indeed, not only in this field but in many others. We are placing upon the Government the obligation of providing a health service, which at first gives rise to the impression of centralization; but although the Minister will be responsible, the service will be worked through Regional Boards and Management Committees of hospitals, which will be voluntary and as far as possible independent bodies."

Some of the Regional Boards had already held their first meetings, and it was gratifying to find so large a body of experienced and zealous people ready to take on this great work at this moment. Mr. Bevan was fully alive to the fact that once the administration started there would arise a chorus of criticism, a cataract of complaints, and people would say, "There you are! It is all going wrong." Actually the complaints had always been felt, but only now would they become vocal. The administration of the Act gave the complainers a means of articulation. The Minister would have to face a barrage of questions in the House of Commons. "That is excellent. That is how a democratic constitution works. And if the Minister is kicked hard enough he passes the kicks on, and the whole service is energized."

The Minister would be sharing with voluntary bodies (Mr. Bevan continued) the responsibility for day-to-day administration. In this experiment of centralized responsibility and decentralized administration a new chapter was opened in the constitution of Britain. Some seemed to think that it would make a dichotomy in the service, whereby the Ministry would be responsible for diagnosis and institutional treatment and the local authority for after-care. "I do not see that that schism actually threatens, because we hope that tuberculosis officers will hold joint appointments with the local health authority. We shall make the link where it is important to make it—at the executive point where the actual work is done."

Next year, on July 5, there would come into operation the National Insurance Act, the Health Act, and—if Parliament passed it (and there was no reason why it should not)—an Act to complete the break-up of the Poor Law system. In three

big steps the social services of this country would have been revolutionized. The Health Act was not merely a contract which the Government made with the citizen; it was a living and developing service, improving with the expansion of knowledge and resources. With the operation of the Health Act, the development of social services generally, the provision of roomy and well-planned houses, and attention to child nutrition, he looked forward to the conquest of tuberculosis.

## "A Fatal Cleavage"

Dr. Norman Tattersall, the principal medical officer of the Welsh National Memorial Association, said that the tuberculosis service in Great Britain was operated by 200 scheme-making authorities, with the result that the standard of achievement varied enormously. Under the new Act institutional provision and the control of the tuberculosis medical staff operated at regional level, but prevention and after-care were left in the hands of the local health authorities. Surely the obvious result would be that those features which came under the control of the Regional Board would reach a certain level of achievement throughout the whole region, but the vital preventive and after-care services would vary according to the vision, energy, wealth, and knowledge of the local authorities.

In most of the small schemes which would now be fused into the regional pattern there was no serious divorce between the preventive and the treatment aspects; it would appear, therefore, that regionalization would ultimately improve their diagnostic and treatment set-up. But would it not also bring about a fatal cleavage—(Mr. Bevan shook his head)—between prevention and treatment? The Minister had just told them that the problem was to be met in some measure by "loaning" the tuberculosis officer to the local authority, so that he would be the servant of two masters—the local authority and the Regional Board—and there was biblical authority for predicting the failure of such an arrangement.

Another defect which Dr. Tattersall pointed out was that while the tuberculosis officer would be in charge of chest clinics attached to the hospitals of the new service he would have no responsibility for cases of non-pulmonary tuberculosis, which would be dealt with by the appropriate departments of the hospital. Surely this meant that the unity of tuberculosis as a disease would be obscured. Admittedly the treatment of particular phases of the infection must be the province of special departments, but in whatever part of the body the main lesion was situated tuberculosis was still an infectious disease combined with a social problem. Of course, the orthopaedic surgeon must advise and direct the treatment of his cases, but if they ceased to be the interest also of the tuberculosis officer it would mean a reversal of the principle which had guided the development of the service ever since Sir Robert Philip opened his first dispensary in 1887.

Dr. Tattersall also asked whether each Regional Board would be left free to develop the service in its area on widely different lines from its neighbours; or would there be such central direction as would ensure a fairly uniform pattern?

"The success or failure of the revolutionary changes which lie ahead will depend in no small measure on the Regulations with which the Minister will clothe the bare bones of the Act. Let him remember St. Paul's advice: 'Prove all things; hold fast that which is good.'"

The discussion was continued by Dr. Brice Richard Clarke, director of the Northern Ireland Tuberculosis Authority, who said that he believed the Act would mean a great advance in diagnosis and treatment, but while they could not expect an Act of Parliament to be as alluring as a company prospectus they would have welcomed indications of a more definite national campaign against tuberculosis. If there was a feeling that enough was being done at present, such complacency was not shared by other countries—Holland, for example. Councillor G. P. Achurch, chairman of the Birmingham Tuberculosis Committee, said that in his city they believed that sanatorium treatment detached from rehabilitation and re-employment was largely ineffectual or at any rate wasteful of effort.

Mr. Bevan could not remain for the whole of the discussion, but before leaving he said that a good deal of misunderstanding

which he had detected in particular in Dr. Tattersall's speech and in the speech of a Glasgow delegate was due to the fact that the Act was merely a sketch. For anything the speakers knew, their criticisms had already been anticipated.

### Tuberculosis in the Commonwealth

Two sessions of the Conference were devoted to reports from the Dominion and Colonial representatives. The secretary of the Canadian Tuberculosis Association, Dr. G. J. Wherrett, described the sanatorium and tuberculosis hospital provision in Canada (one bed per 1,000 population) and said that treatment was free for all in five of the nine provinces and in others not more than 10% of the patients had to pay. B.C.G. vaccine was first used in Canada in 1928, in the vaccination of newborn babies from tuberculous households in Montreal. The results of B.C.G. were shown in a significant reduction in the morbidity and mortality in the vaccinated as compared with the unvaccinated groups. Dr. F. J. Wiles (Union of South Africa) said that the medical authorities on the Rand gold mines were the first in the world to start mass radiography. He referred to the low incidence of the disease in the native reserves. One rural community of 2,000 Bantu was kept under observation for eight years and during that period only three people died from tuberculosis. Investigators had found over 65% of the population in rural areas tuberculin-positive, and in a recent survey 73% of children under 15 were positive. There must be ample opportunity for infection in the reserves, but despite this the mortality was relatively low. Mr. W. H. Kitson, agent-general for Western Australia, said that the government of his province had undertaken a programme of mass radiography of the civil population.

Other speakers were from New Zealand and India, and, at a subsequent session, from Cyprus, the Gold Coast, Ceylon, Fiji, Singapore, and the West Indies.

Mr. A. Creech Jones, Colonial Secretary, in addressing the Conference on the colonial aspects of the anti-tuberculosis campaign, acknowledged the debt which the Colonial Empire owed to the National Association for the Prevention of Tuberculosis. Through the agency of that body, he said, detailed surveys of tuberculosis in the West Indies and in Cyprus had been carried out, and others were envisaged.

### B.C.G.

An important session was devoted to specific measures in the prevention and treatment of tuberculosis, including B.C.G. and streptomycin. The chair was taken by Prof. S. Lyle Cummins. Prof. W. H. Tytler, of the Welsh National School of Medicine, said that for specific immunization there was only one well-established method—namely, inoculation with the bacillus of Calmette and Guérin (B.C.G.). Its only prospective rival was the vole bacillus, or murine tubercle bacillus of Wells. Specific treatment to-day meant streptomycin; here again there were some potential competitors in the background. Before he died in 1933 Calmette claimed that among a million vaccinated not a single case had been proved due to B.C.G. culture, and that claim remained unrefuted to-day for double the total. The effectiveness of the method was more difficult to assess. The earlier French statistics were open to criticism, but the impression remained that the reduction in deaths was real. In countries where child tuberculosis had decreased under improved control the interest in B.C.G. as applied to infants had waned; its main interest to-day arose out of its new use in the immunization of those who had reached adult life uninfected and therefore non-immune. Immunization of young adults was applied mostly to those in contact with infection, such as nurses and medical students, but it was steadily being extended to the whole population in a number of countries. As the infection rate in childhood fell, more and more people would reach adult life uninfected and, so long as infection was widely present in the community, would require artificial immunization.

Touching on streptomycin, Prof. Tytler left the question of its value to later speakers, but he said a word on what it could not do. It could not cure advanced tuberculosis in the dramatic way in which penicillin acted on acute infections. He himself thought they were more likely to have prevented advanced tuberculosis before they were able to cure the disease rapidly.

Streptomycin had produced some striking results in certain limited forms of tuberculosis and it had had a generally favourable effect in early pulmonary disease. For these effects alone it was probably worth while going on with its expensive production, but it was difficult to hold a proper balance between, on the one hand, crying down a drug which did not produce dramatic results and, on the other, expressing a too favourable opinion which would raise public hopes.

Dr. K. Neville Irvine, medical superintendent, South Oxfordshire Isolation Hospital, said that he understood that B.C.G. vaccine was shortly to be introduced into this country in a manner in which it could be fitted into existing tuberculosis services. Ideally, B.C.G. vaccination should be carried out first by segregating all the tuberculous members of the community, Mantoux-testing the remainder to see if they had ever had a tuberculous infection, putting aside the Mantoux positives as having already their acquired immunity, and inoculating the Mantoux negatives with B.C.G. vaccine, allowing six weeks for their immunity to develop. A scheme formulated on these principles, though feasible in Great Britain, would be impracticable in remote native villages, and he suggested for such territories a greatly simplified scheme, using the existing service for the vaccination of the natives against smallpox. Empire laboratories should be suitably placed for the production of B.C.G. vaccine, which should be issued direct to the vaccination service. A subsequent speaker, Dr. K. S. Sanjivi, of Madras, as representing a country with communities heavily infected with tuberculosis, thought that Dr. Irvine's plan was dangerous over-simplification.

### The Vole Bacillus

Dr. Arthur Quinton Wells, of the Sir William Dunn School of Pathology, Oxford, compared B.C.G. with the vole bacillus, the murine strain of tubercle bacillus widespread among small rodents. He agreed that the safety of B.C.G. was beyond dispute, and that it would be wrong to make so categorical a claim for the vole bacillus, but from the limited experience he had had and the few published reports the vole bacillus was innocuous to man. He had vaccinated 121 persons by various methods, nearly half of them three years or more ago, and the remainder about a year ago, and no cases other than of a purely localized disease had been seen. The local reaction caused by the vole bacillus in man was dependent on the depth of the injection into or beneath the skin. A subcutaneous injection frequently gave rise to a severe reaction, manifested by an indolent ulcer which might take many months to heal. He had abandoned that route of injection. The least troublesome reaction followed injection of the vaccine by multiple puncture, involving a number of simultaneous pricks into the skin. He admitted that there was no actual evidence that the vole bacillus reduced the incidence or severity of tuberculosis in man; there was, unfortunately, no known method of measuring human resistance, but if it was agreed that tuberculin-positive persons were less likely to contract tuberculosis it was interesting to note that reports from this country and overseas agreed that sensitivity to tuberculin following vaccination with the vole bacillus was greater and occurred earlier than that following vaccination with B.C.G.

### American Work on Streptomycin

Dr. H. S. Willis, superintendent of the W. H. Maybury Sanatorium, Michigan, and Dr. H. C. Hinshaw, of the Mayo Clinic, then told the story of streptomycin. Dr. Willis said that in the United States to-day six or more excellent laboratories were making explorations into streptomycin the chief feature of their research work. In the clinical field about 1,000 patients had completed their experience with streptomycin—an average course of from 90 to 120 days—and 600 more were now under study. Plans were also proposed for the regular clinical application of the drug to several hundred others, these apart from many more who were treated privately and without regard to study regimes. As a result of the work to date the use of streptomycin was regarded as "mandatory" in miliary tuberculosis and tuberculous meningitis, also in acute pulmonary tuberculosis, and in certain extra-pulmonary lesions. Here the application of streptomycin was "as essential as the use of anaesthesia in operations."

The research work on streptomycin was a co-operative venture in which the National Tuberculosis Association (Medical Section), the Veterans Administration, and the U.S. Public Health Service were concerned. A committee on streptomycin, of which Dr. Hinshaw was chairman, obtained 54 kg. as a donation from the manufacturers. The drug was parcelled out among eight investigators, whose work was co-ordinated by the committee. It was now well known that the average strain of tubercle bacillus sensitive to streptomycin at the beginning of therapy for some reason became drug-fast after the patient had had several weeks of treatment. The nature of this resistance was being explored, because it was an important factor in bringing about discontinuance of streptomycin treatment. Other laboratory studies consisted of investigations of dosage and the toxicity of the drug as it related to blood levels and its use in patients with damaged kidneys. The clinical work with patients was divided into two parts, one of them pioneer and testing, and the other mass application. Pilot studies had been made in connexion with several types of tuberculosis in which variables in dose and dose schedules were used. At present the acceptable cases fell into the following categories:

- (1) Cases of bad prognosis in which some improvement seemed likely;
- (2) Cases of bilateral acute disease not amenable to collapse therapy;
- (3) Cases in which the lesion was known to be recent and progressive;
- (4) Cases in which the patient had collateral symptoms out of proportion to the degree of pulmonary involvement.

The reason for co-ordinated effort was obvious in the study of a drug in so important a disease as tuberculosis. In ordinary circumstances someone evolved a drug or biological product with certain bactericidal or bacteriostatic properties and published a report. Another investigator read the report and decided to try the drug on animals. Then experimental pathologists took it up and confirmed or refuted the claims. Meanwhile clinicians decided to apply the product to patients, and in due course the results of these observations became common knowledge. But it often happens that enthusiastic workers were found to have claimed too much, the public were misled, and the general establishment of the treatment delayed. Co-ordinated effort justified itself when entered into by investigators for a given section of work and for the accomplishment of a certain job, recognizing that research needed and must have independence of thought and action. It was felt in the U.S.A. that very real progress was being made against the disease by the use of this drug; but only a relatively small proportion of all cases of tuberculosis were amenable to the drug as used at present, and streptomycin in no way replaced conventional methods of therapy.

Dr. Hinshaw added that the clinical work started less than three years ago, and the total number of cases reviewed to date was nearly 1,000. Streptomycin was being produced on a large scale commercially, probably about 500 kg. per month. He agreed that over-enthusiastic evaluation was a tragedy, and it was unfortunate that the discovery of streptomycin did not precede that of a drug like penicillin, of which it was not the equivalent. Unless all other forms of therapy were unavailing streptomycin should not be regarded as a satisfactory substitute for existing methods of treating pulmonary tuberculosis, but in tuberculous meningitis it might be found that its use would halve the death rate.

Dr. Selman Waksman, the discoverer of streptomycin, who was given a hearty reception by the Conference, said that he hoped to deal fully with the question at the International Congress of Pure and Applied Chemistry which is being held in London at the end of July. Streptomycin might not be the final word, but it pointed the way.

#### Spanish Work

Prof. F. Bustinza mentioned the work of two Spanish colleagues—Dr. Urgoiti, of Coruna, and Dr. Gaston de Iriarte, of Madrid. Dr. Urgoiti had been working for 15 years on anti-tuberculosis prophylaxis with B.C.G. and during the last 12 years had used the vaccine not only for the protection of the newborn but also for non-infected children and adults who were negative to tuberculin tests. He believed it to be a

weapon of great efficacy. Dr. de Iriarte had devoted himself for 17 years to experimental study of anti-tuberculous vaccine therapy. The vaccine he used was prepared with *Mycobacterium tuberculosis* isolated from the patient and grown on a fluid medium, and he had used the filtrate in treatment with ultra-violet rays. Dr. Bustinza suggested that possibly the substance responsible for the antigen preparation might be some kind of polysaccharide present in the metabolic liquid in which the tubercle bacillus had been cultivated. If sufficient human tests confirmed the excellent results already obtained with this vaccine in animal experiments its use in combination with streptomycin might be found to give better results than either used alone, the streptomycin checking the growth of the tubercle bacillus and the other preparation bringing about the development of a specific immunity necessary for a complete success.

Dr. Esmond Long, director of the Henry Phipps Institute, University of Pennsylvania, said that he was wholly in accord with Prof. Tytler's views as to the possibilities and limitations of B.C.G. immunization. In the U.S.A. they had been cautious in the use of B.C.G. vaccine, first because they realized the need of rigid insistence upon statistical analysis of results, and, secondly, because the campaign against tuberculosis, as in Great Britain, was proceeding successfully. As Dr. Tytler had said, there were many reports for and against B.C.G. vaccination, perhaps the minority on the negative side; but the results obtained by men of impartial outlook and accustomed to statistical inquiry could not be ignored. Everybody would agree that B.C.G. was harmless for man, but there were reports of variations in strength, and some strains produced more significant skin reactions than others.

#### M.R.C. Experiments

Dr. P. M. D'Arcy Hart, member of the Scientific Staff of the Medical Research Council, who wound up the discussion, said that at the end of 1946 the Medical Research Council was provided with about 50 kg. of streptomycin imported in bulk from the U.S.A. The amount was sufficient for the treatment of 150 to 200 cases. A special "T.B. Trials" Committee was formed, Dr. Geoffrey Marshall presiding, and a "Non-T.B. Trials" Committee, with Sir Alexander Fleming in the chair. A small number of centres were opened, two in London, one in Glasgow, and one in Liverpool, and these had been increased until there were now eight meningitis centres in the country. The centres were all in hospitals with specialist staff available, and so far 60 patients had been placed in the centres. A small number of cases of acute miliary tuberculosis had been accommodated at three centres, and there were also some 40 or 50 cases of pulmonary tuberculosis under treatment, thanks to the co-operation of local authorities. It was much too early to assess the results with these last. It was evident that streptomycin benefited at least a small proportion of sufferers from meningitis and miliary tuberculosis, though the long-term results were in doubt. The results were sufficiently promising, however, to justify considering the wider use of the drug in these two diseases. Although British production was going forward, they were dependent on importation and on American allocation. Even when supplies became easier a proportion would be required for a long time for research in tuberculous meningitis, not to mention other forms of tuberculosis, especially pulmonary, where the results were much less definite. But the discovery of streptomycin represented the first real break in the struggle for specific treatment of certain forms of tuberculosis, and it was likely to be followed in the course of years by a stream of natural or synthetic drugs.

Striking claims for the value of B.C.G. in tuberculin-negative children and young adults exposed to more than average infection and in mass immunization of negative members of whole population groups had been made in a number of countries, particularly Scandinavia. A cautious approach was still evident in the U.S.A., and the same might be said to be true of Great Britain. As a balanced view it might be said that B.C.G. appeared to be of some value in grossly exposed persons, though degree of response and duration were still uncertain. The value in mass immunization seemed less clear. The danger of indiscriminate use in whole population groups was

the slackening of responsibility in other preventive fields. The Ministry of Health had authorized him to say that, having had under consideration for some time the necessary preliminary arrangements for the production of B.C.G. vaccine, it was now in a position to allow the production to go ahead. What use to make of the vaccine when produced should be the subject of careful discussion. It might be that it should be made available for further research by tuberculosis authorities in respect of tuberculin-negative infants in tuberculous families. More research was needed on the degree and duration of protection, and for this purpose controlled trials might be valuable. It seemed improbable that any well-tried methods of attack on tuberculosis would be abandoned, and they would all agree that the most important factor in lowering the incidence of tuberculosis in any community was a steady rise in the standard of living.

## THE ROTUNDA BICENTENARY INTERNATIONAL CONGRESS

The International Congress of Obstetricians and Gynaecologists held in Dublin from July 7 to 11 attracted nearly 600 doctors from all over the world. Nowhere could they have been more hospitably received or entertained.

The Congress was opened by the President of Eire, who welcomed the delegates first in Irish and then in English. Sir Eardley Holland presided over the first brief session on the history of midwifery, and then the real business of the Congress began with six papers and a long and lively discussion on puerperal sepsis. In the evening An Taoiseach, Mr. de Valera, attended the reception in the Royal College of Physicians of Ireland given by Dr. and Mrs. Bethel Solomons. He was also present at the Tuesday evening reception given by the President of Ireland and Mrs. O'Kelly at Arus an Uachtairain. This was a reception in the grand manner with a thousand guests converging on Phoenix Park. Ministers of State, diplomats, and dignitaries of the Church strolled amicably on the great lawns, where green-kilted pipers were performing evolutions as complimented as the day's discussion on eclampsia had been.

On Wednesday there was a garden party in the grounds of the Rotunda Hospital. Dr. Ninian McL. Falkiner and Mrs. Falkiner received the guests, most of whom seized the opportunity to admire the chapel and to look in on a pathological display in the out-patient department. There was also an excellent film, and a conducted tour round the hospital. Many of the foreign visitors seemed to be most impressed with the clutch of premature babies incubating happily in air-conditioned splendour. Later the delegates were the guests of the Medical Association of Eire at a reception in University College, where they were received by Dr. A. Ryan, the President of the Association, and Mrs. Ryan. The Congress Dinner was on the Thursday, and on Friday a sherry party arranged by the Editors of the *Irish Journal of Medical Science* was followed by a special performance at the Abbey Theatre.

### Exhibitions

There were two exhibitions. Dr. James Ryan, the Minister of Health and Social Welfare, opened the one at the Mansion House, where 44 firms contrived to display their wares in a manner that would barely have been adequate for half that number. White panelling, chromium plating, and skilful lighting attracted the curious. They were then exhorted by bright young spellbinders who, despite their accents, might well have been born within shouting distance of Blarney Castle. Less obtrusive and nearly as popular was the exhibition of books and manuscripts which Dr. J. D. H. Widdess had arranged in the library of the Royal College of Surgeons in Ireland. Noteworthy exhibits were McBride's case-book and his notes on Smellie's lectures; the book of sedan chair licences issued by the Governors of the Rotunda; early minute books of the hospital; and the Master's Book for 1793 and some more recent years. Also displayed was a copy of the *Speculum Matricis*, or the *Expert Midwives' Handmaid* of 1671. It is the rarest of all midwifery books. The only known specimen of a Rotunda Hospital Governor's Pass was also displayed. It was from this Metal Pass that the design was made for the Bicentenary Congress badge.

Though this was a Rotunda Bicentenary, both the Coombe and the National Maternity Hospital had their share of visitors and took as active a part in entertaining them. Thanks to the Sweepstakes funds large sums have been spent in recent years in extending the Rotunda. The National Hospital has been newly built and finely equipped and the Coombe is next in line for a new building.

### Six Sessions

Justice will be done to the six sessions of the Congress only when the *Transactions* are finally published. Ireland fortunately seems to have no shortage of paper. On each subject there were one or two outstanding contributions, and it was noteworthy that they came as a rule from the pathologists and bacteriologists, from the laboratory rather than the labour ward. The least satisfactory morning was that devoted to eclampsia. Dr. Gibbon FitzGibbon, a former Master of the Rotunda, paid a tribute to Tweedy. Dr. Falkiner, the present Master, said that he had never been able to subscribe to the theory and method of treatment propounded by Tweedy and promoted by his successors. Other speakers were just as divided on questions of aetiology and of treatment. Prof. H. J. Stander, of New York, presented a classification of old and new theories of causation and seemed to sum up the general feeling with his considered conclusion: "There are more than enough theories. What is needed is more data!"

One of the most satisfactory sessions was that on shock in obstetrics. One speaker after another urged the abandonment of Crédé's manoeuvre for expression of the placenta and stressed the need for blood or plasma given early and often. In this as in other discussions all the speakers seemed concerned about the problem of improving the standard of obstetric practice of the general practitioner. The point was well put by Prof. J. P. Greenhill, of Chicago. In the final session on foetal and neonatal mortality he quoted Yerushalmy's estimate that 1,225 conceptions were necessary to produce 1,000 infants surviving their first year of life. Foetal lives could be saved by proper antenatal care and by the prevention and treatment of proper maturity, birth injuries, and the toxæmias of pregnancy. Ideal antenatal care should start with a thorough examination "before she plans to become pregnant." Then he went on to say that obstetricians were aware of the methods of preventing many foetal and neonatal deaths, but they conducted only a very small proportion of deliveries. Any future reduction in maternal, foetal, and neonatal mortalities could be achieved only by the proper training and instruction of students and practitioners. The same point was brought out in the session on puerperal sepsis and, with a different emphasis, in that on sterility.

This was a successful Congress and it was clear to everyone attending it that those responsible for its organization must have been planning carefully for two years and working hard for at least six months. Yet every day showed again the dilemma peculiar to Congresses of this kind. Many of the opening speakers were reading thoughtful papers which were intended for publication. They may well make good reading but they are not easy to listen to, and Prof. Subodh Mitra, of Calcutta, had the courage to say in one general discussion that he had been disappointed. He had, he said, not travelled all the way from India to listen to a series of postgraduate lectures. What he wanted was the to-and-fro of discussion, and the length and number of the opening papers left too little time for this. In an attempt to meet this difficulty later sessions were conducted on exact time-limits with the offenders being ruthlessly "gonged." This helped in some instances, but was unfortunately in that at least one distinguished visitor was cut short in the middle of a carefully prepared thesis.

All the sessions were recorded, and, for those who wanted to listen again, could be played back. It may be that the Editors of the *Transactions* have a verbatim account in mind. This was a notable Congress, a cordial demonstration of Irish hospitality, and a fitting celebration of the Bicentenary of the Rotunda.

On the appointed day for the National Health Service all hospitals vested in a local authority will be transferred to the Ministry of Health. The Minister has therefore asked local authorities to inform him of interest in land and premises held by them on March 31 of this year for hospital purposes.

## Reports of Societies

### BRONCHIECTASIS IN CHILDREN

A meeting of the Faculty of Radiologists was held in Birmingham on June 26 and 27, when discussions were arranged on bronchiectasis in children and on primary bronchogenic carcinoma, and various other papers were read.

Prof. J. M. SNEELLIE, of the Children's Hospital, Birmingham, defined bronchiectasis as a permanent dilatation of one or more bronchi, in association with chronic inflammatory and degenerative changes, a progressive disease, localized or diffuse, affecting any part of the lung but uncommon in the upper lobes. He discussed the aetiology, symptomatology, and physical signs. A few cases arose without any antecedent history of respiratory infection, but in the large majority one or more attacks of pneumonia was the common story. In a series of 34 cases recently investigated at his hospital three-fourths gave a history of antecedent pneumonia, half of them associated with whooping-cough. The significance of early symptoms could not be overestimated. Cough, usually dry in the early stages, was an almost constant symptom. A common story was repeated attacks of bronchitis. Pain in the chest was rarely complained of, and haemoptysis was infrequent. Anaemia, night sweats, dyspnoea, and clubbing of fingers were evidences of advanced and widespread disease.

Physical signs varied widely. In general the signs were those of bronchitis. At their best, physical signs could never be more than suggestive and might be misleading. For decisive diagnosis radiological examination of the chest following the introduction of lipiodol was essential. To wait until the radiological picture was unequivocal in a straight postero-anterior or lateral film was to wait too long. Until recent years treatment had been largely medical, but brilliant advances in thoracic surgery and in chemotherapy had already revolutionized prognosis in the established case and focused attention on the importance of diagnosis at an early stage. The keynote to prophylactic therapy was promptness in the treatment of all children suffering from pneumonia whose resolution was delayed. Elimination of sinus infection, combined with penicillin sprays and aerosols, was a major measure. At a later stage, when some dilatation of the bronchi was demonstrable, medical measures might still suffice, but treatment must be energetic, sustained, and continuous. Upper respiratory tract infection must be treated, postural drainage instituted, inhalations of penicillin employed. The practice adopted at his hospital in cases of early bronchiectasis was inhalations of 20,000 units of penicillin dissolved in 1 ml. of isotonic sodium chloride in a nebulizer, each inhalation being continued for 8 to 12 minutes and repeated three-hourly seven times in 24 hours. In cases of frank bronchiectasis lobectomy was now recognized to be the best treatment. Here again, however, a full course of medical treatment should be given before operation.

Dr. JOHN C. BISHOP supplemented this contribution with a paper dealing more particularly with radiographic technique. The radiological diagnosis of bronchiectasis, he said, depended on two separate procedures, the examination of the routine radiograph and of the radiograph made after the introduction of radio-opaque oil into the bronchial tree. The routine film of the congenital form would vary according to whether the cysts had or had not become infected. That of the acquired form was far less typical, and the appearance might range from that of normality to gross radiological disease. It was on the bronchogram that the diagnosis of acquired bronchiectasis must be based. He indicated the findings which demanded a bronchogram.

Dr. Bishop then summarized the four methods used for introducing the oil into the bronchial tree—namely, the supra-glottic, the endotracheal, and the intranasal routes, and crico-thyroid puncture. For children the choice lay between the last two, and every case must be considered on its merits. In any case postural drainage was an essential immediate preliminary to ensure that the bronchi were as empty as possible. At the Children's Hospital, Edgbaston, for the past few years

the intranasal method—the oil being injected directly into the nasal cavity, with the tongue pulled firmly forwards—had been used, with a general anaesthetic. To his constant amazement the oil trickled down through the larynx—incidentally a pretty demonstration of what might be the fate of the discharge from an infected sinus when the cough reflex was dulled by sleep.

### Primary Bronchogenic Carcinoma

In the second principal discussion Dr. THOMAS LODGE, of Sheffield, reviewed 130 cases of primary bronchogenic carcinoma, of which 55 had been confirmed by biopsy, bronchoscopy, or necropsy. The predominant symptoms in order of frequency corresponded roughly with other published series. In 32% of the cases the pain was entirely on the side of the tumour. The pain was higher in the chest with upper lobe lesions and in most cases was not at first associated with pleural effusion. In distribution the disease seemed to have a predilection for the right lung. As for radiological types, the largest group showed collapse, which supervened rapidly rather than slowly. Bronchiectatic collapse in a patient of cancer age, with cough, pain, loss of weight, and dyspnoea, should be regarded as due to cancer until proved otherwise. The hilar type accounted for the next largest group. This type of appearance, without collapse, usually meant that the peribronchial or tracheo-bronchial lymph nodes were involved and that surgery was not likely to be successful, though some cases of the so-called hilar type, as seen in postero-anterior projection, were really segmental in distribution, and offered the surgeon a better chance of removal. The peripheral carcinoma was a commonly occurring form.

Bronchography showed an early intra-lumen lesion more convincingly than tomography, especially when the bronchus was not greatly narrowed, as in some inflammatory conditions. But tomography had many important uses, especially in the peripheral growth. It brought out the typical ragged thick-walled cavity of the breaking-down growth, not visible in the straight radiograph, or the peripheral tumour beginning to reach out along the lymphatic pathways towards the hilum.

Dr. A. BRIAN TAYLOR said that there was no doubt that carcinoma of the bronchus was occurring more frequently than formerly; this increase was absolute and not due merely to improved diagnosis. From 1936 to 1943 at the Birmingham United Hospital there were 604 cases. The preponderance in males, 5 to 1, was striking, and the average age, 54, compared closely with other series of figures. The disease was rapidly fatal, and though a few cases survived for periods up to 39 months, the average duration of life after diagnosis was 4 months. A suitable case for pneumonectomy was one diagnosed early enough for a radical resection of the lung which could remove the whole growth before extension to neighbouring structures or glands had occurred and while the patient's general condition made the operation itself feasible. But it was early diagnosis that was difficult. Radiology offered great help in many cases, but in the earliest stages a small lesion in the region of the hilum might show little or no significant shadow. Bronchoscopy was the final and most valuable method of diagnosis.

Mr. A. L. D'ABREU said that although many successful pneumonectomies were performed, a large number of cases were quite inoperable when first seen by the surgeon. After mentioning the criteria of inoperability and describing the operable case, he said that he had the conviction that in the treatment of lung carcinoma there was not sufficient co-operation between radiotherapists and surgeons. When a surgeon referred a case for irradiation he should state whether the treatment expected was palliative or radical. The exact bronchoscopic findings giving the precise position of the growth should be clearly stated so that the therapy could be directed to the lesion itself and not, for instance, to the resultant atelectasis.

Among other speakers Dr. PETER KERLEY gave a statistical review of carcinoma of the lung based on the mass radiography figures of the Registrar-General and the Ministry of Health, but as both these departments had requested him not to publish the figures he had to tell the meeting that for the time being they were confidential.

### Medicine in the United States

SIR,—Being a very young doctor, it is with some diffidence that I criticize our old-established customs and institutions, but the letter of Dr. S. L. Simpson (June 28, p. 949) shows up in sharp contrast to many of the criticisms I have heard from my friends and seniors about medicine in the U.S.A.

I spent 2½ years at medical school in Boston, with a three-month break to visit Johns Hopkins, and feel justified in making a few comments on the contrast between these schools and our own London and university teaching systems. Without doubt the most inspiring teaching that I have ever had was at Harvard Medical School; and yet, taken as individual teachers, some of those from whom I have been privileged to learn in this country are without equal anywhere. It was not the system of teaching at Harvard that impressed me, with its frequent examinations throughout the course, which came first as a rude shock and then as a rather unpleasant stimulant to one used to the more haphazard and individualistic Cambridge ideas, but the atmosphere. It was the continual thirst after new knowledge of our teachers and the way in which they accepted all criticism and questioning, whether from students or colleagues, as genuine attempts at furthering knowledge rather than sly traps by rivals. Everyone was kept very much alive, and a spirit of friendship and co-operation pervaded.

Dr. Simpson mentions the "collaborative sessions" at the Peter Bent Brigham Hospital. One of these was a weekly event called the "Clinico-Pathological Conference" and locally known as the C.P.C. (The Massachusetts General Hospital also had one weekly.) These were so good and so helpful to us as students that I feel justified in describing them in the hopes that a similar session may be introduced into some of our hospitals. They were organized by the pathology department, which would collect the notes from an old case that had been treated in the hospital and extract them on to a mimeographed sheet containing: (1) the patient's complaint as described by himself; (2) the past history of the patient up to admission; (3) the clinical findings as recorded on entry and the relevant laboratory findings; (4) a very brief outline of the patient's course in hospital, finishing with either "an operation was performed" or "the patient died." These sheets were distributed to all those attending, and a guest speaker, usually from another hospital but certainly a doctor who had no previous knowledge of the case, was invited to discuss the diagnosis and therapy. X-ray films were provided, and he could, if he wished, ask for and expect advice on any points outside his own specialty. The case was always chosen taking into consideration the speaker's special subjects, so that we could listen to an expert analysing a case in his own field. The speaker would go through the case point by point giving his differential diagnoses and stating how he thought the recorded course of the patient fitted these or ruled them out. At the end, if the case was surgical, the surgeon who operated would tell of his findings, or, if medical, the pathologist would give the necropsy findings, illustrated with photographs and sections on the screen. The speaker was often wrong in his diagnosis, because the cases were difficult and had often caught out the staff of the hospital, but no one was offended and everyone felt that they had gained by the experience.

Latterly the Brigham went further, and final-year students, usually about eight at a time, were occasionally briefed a week beforehand for the discussion, being given the case history to think about. This gave them a chance to look up the relevant literature. (I believe that most of the speakers were given some warning.) On the appointed day the students took the front seats and one was drawn by lot to speak. This victim then had to discuss the case before his teachers. These conferences were voluntary but were very well attended, being one of the most popular features at the medical school.

There is just one other point that I should like to make emphasizing a statement in Dr. Simpson's letter, because I hear so much about the American laboratory diagnostician. I had more teaching in psychosomatic medicine at Harvard than I have seen or heard of in England. Also my instructor in medicine once said to me, "If the laboratory data do not agree with your clinical findings, have the tests repeated. If they still do not agree, neglect them." The laboratory work at Harvard is not a short cut to diagnosis but an adjunct to research and sometimes a gauge of the patient's progress under treatment. My criticism of medicine in Boston is that it aims too much at research, if that is possible.—I am, etc.,

Dr. Camh.

N. K. CONNOLLY.

### World Medical Association

SIR,—In the Supplementary Report of Council (Supplement, June 21) I was very glad to see that the Council had prepared a statement to be submitted to the General Assembly of the World Medical Association in September, 1947. As I have been appointed by the Medical Women's International Association in my capacity as their honorary treasurer to act as an observer at the meeting of the Assembly, I should like to take the opportunity of saying how strongly I agree with the Council's view that the medical profession as a whole have a grave responsibility towards their fellow men, not only as doctors but as leaders of public opinion in the field of moral and ethical values.

During the terrible years of occupation by a brutal enemy the large majority of doctors of most of the occupied countries maintained their moral integrity, their unswerving loyalty to their patients, and their spiritual and professional freedom, even at the risk of torture and death. They thereby set a great example and vindicated the honour of their profession.

Now that the war is over we are faced with a curious and dangerous shift of values. On the one hand men and women in so many countries are refusing to submit in any particular to the power of individual employers, while on the other hand they appear willing and even eager to denude themselves of every vestige of personal and political freedom and to surrender all their liberties to the State. This must lead insidiously but surely, as it did in Germany, to a growing disregard for the value of the life and human rights of the individual. As the Council so truly says in its statement, "The doctors who took part in these deeds (i.e., medical war crimes) did not become criminals in a moment. Their amoral methods were the result of training and conditioning to regard science as an instrument in the hands of the State to be applied in any way desired by its rulers." The Council might have added that the doctors were trained and conditioned to regard human beings, including their patients, as mere robots or sub-human statistics entirely unimportant in themselves, and therefore subordinate to the will and interests of the State and its rulers.

This horrible distortion of values is one which doctors have an especial duty and, if we will only use it, a considerable measure of power to resist and overthrow wherever we find it developing in our midst. The principles which are included in Appendix 2 to form a part of a Charter of Medicine are fundamental, but I would suggest that they should be extended to include a statement that the medical profession affirm their belief in the sanctity of the rights of the individual as a human being, and pledge themselves to safeguard these rights in all their dealings both with their patients and in relation to any function which they may be called upon to exercise in their capacity as medical men and women. Let us never forget that "the price of freedom is eternal vigilance."—I am, etc.,

London, W.1.

DORIS M. ODLUM.

### Symmetrical Gangrene in the African

SIR,—The condition described by Dr. Michael Gelfand (June 14, p. 847) appears to be of sufficient rarity to justify my quoting an almost identical case which fulfils his six diagnostic criteria. The patient was seen in the province of Sidamo, Ethiopia, in 1945.

#### CASE REPORT

An adult male Sidamo aged between 30 and 35 was brought by his friends from a village some long distance away. He gave history of being in good health and symptomless until some 3 months previously, when quite suddenly he had an attack of "rheumatism" in his legs and feet, which became swollen and painful. A little later the toes and soles of his feet appeared "as though dead." There was no history of recent attacks of malaria, typhus, or other disease. He had had syphilis at least ten years before, for which he had not received any treatment. His general nutritional state was good, and his diet appeared satisfactory.

On examination a condition rather similar to that shown in Gelfand's first photograph was seen, though more advanced. Both feet were blackened, dry, and wizened, particularly on the under side, and flies were crawling in and out of the various cavities in the mummified gangrenous area. The line of demarcation was not as pronounced as is shown in Gelfand's second photograph, but ran from about 1½ in. (3.81 cm.) proximal to the base of the toes just below the level of the malleoli. No pulsation could be felt in the dorsalis pedis or in the femoral artery of either side. There was

apparent slight hyperaesthesia proximal to the line of demarcation, which might be explained by the band of hyperaemia as described by Gelfand. Knee-jerks were indeterminate. Wassermann examination and blood counts could not be performed. The urine was free of sugar and albumin.

The patient refused operation and would not enter hospital, so his further progress is not known.

Williams (1939), discussing the results of 894 post-mortem examinations in Uganda, found 86 cases showing syphilitic arterial disease and considers that this is common in East Africa. Coombs (1932) points out that lesions most commonly follow one, two, or more decades after infection. This would fit in with the age groups of both Gelfand's and my cases, particularly when it is remembered that the African often acquires his syphilis relatively early in life.

Prior to Gelfand's paper I had considered my case to be definitely one of syphilitic origin. Now the question requires reconsideration. It may be that the part played by syphilis is merely an initial damage to the artery (Gordon *et al.*, 1942), on which further processes later bring about an ischaemia sufficiently suddenly to cause gangrene. On the other hand in cases where gangrene has followed syphilis the onset has usually been much less sudden than in these seven cases. Choussat (1938), for instance, describes a case of bilateral dry gangrene of the feet, of slow onset, in a child of 10. Bilateral gangrenous areas on the arms of a white woman of 61, in which the lesion on the left preceded that on the right, is cited by Goodman (1939). Similar cases will be found in papers by Fusco and Kell (1943) and Leone Bloise (1936), though I have personally not yet been able to trace them.

When the high rate of syphilis in certain native populations is taken into account, figures ranging from 23% (Kark and Le Riche, 1944) to 40% (Rauch and Saayman, 1938) being substantiated by various authors, the fact that three out of these seven cases of bilateral gangrene of the feet had syphilis may not be of significance but merely a coincidental finding.—I am, etc.,

#### Peptic Ulcers and Radiology

SIR.—It was with considerable interest that I read Dr. A. Landau's contribution under "Medical Memoranda" (June 28, p. 928) in which he describes a case of peptic ulcer responding rapidly to a line of treatment advocated by himself. Without wishing to comment on the efficacy of the treatment described by Dr. Landau I would like to point out that it is not an uncommon experience among radiologists to find an apparently large gastric ulcer become almost undemonstrable radiologically after a few weeks' medical treatment on the usual accepted lines. This is due mainly to the fact that the apparent depth and size of the ulcer, as demonstrated on the x-ray film, is much greater than the actual depth. Most of the apparent depth is made up of the swollen oedematous edges of the ulcer projecting into the lumen of the stomach, while the actual ulcer crater is often quite shallow, as has been demonstrated at operation.

On conservative medical treatment the first thing to subside is the oedema, thus producing apparently rapid healing radiologically, but the actual shallow ulcer crater can often be demonstrated for some time after the initial rapid reduction in size. The first x-ray photograph illustrating Dr. Landau's case (allowing for loss of detail in reproduction) would appear to show one of these typical apparently large craters with some narrowing of the neck and projection inwards of the oedematous edges. If the normal line of the lesser curve is followed, it will

be found to include only a small proportion of the ulcer base, which is probably the true depth. In view of the above points I am of the opinion that to describe this ulcer as "the size of a cherry" is misleading in the assessment of its ultimate progress with regard to the treatment described.—I am, etc.,

Orpington, Kent.

RONALD L. MANSI.

#### The Thalamic Syndrome

SIR.—Any new approach to the treatment of psychoses is welcome in view of the limited value of present methods. I do not think, however, that the dogmatic statements with which Dr. G. Tayleur Stockings (June 28, p. 918) prefaces his account of work on a drug resembling Indian hemp are very helpful. He blames the thalamus for the symptoms associated with reactive depression, the list of which reads like a proprietary medicine advertisement. The logic of this claim is, however, not apparent. To pick out two of the symptoms at random, it is not clear on what evidence tremors and obsessional thoughts are attributed to dysfunction of the thalamus. True, Stockings goes so far as to admit that the hypothalamus may also be involved in "the thalamic syndrome," but why seek to exclude any part of the brain from involvement in this pantechnicon syndrome? At one point the thalamus is referred to as a "higher centre." It would appear to have been promoted recently. In fact the majority of the symptoms which he describes as being produced by the drug under investigation, which Stockings refers to as having a specific effect on the thalamus, appear to be at least equally attributable to cortical changes. Thus photopsias, simple coloured patterns, visual illusions, increase in the power of phantasy, and vividness of visual imagery are surely not characteristic of thalamic activity.

In the past there has been a tendency to neglect the thalamus as a factor in the production of neuroses and psychoses. This fault will not be remedied, however, by swinging violently to the other extreme. What is needed now is an effort to see the brain as a functioning unit with the different centres balanced harmoniously, one against the other. This dialectical concept would avoid the clumsy attempt to divide off "neurotic depression" artificially from psychotic depression, and to divorce it on the other hand from environmental factors, and to pin it for the sake of formal neatness on to one particular region of the brain.

Incidentally, Stockings states that the "true addiction syndrome" is peculiar to morphine and cocaine. I had always been under the impression that alcohol sometimes caused addiction, but possibly this drug is now in such short supply that it can be neglected.—I am, etc.,

St. Mary Cray, Kent

BRIAN H. KIRMAN.

#### Vaccination against Variola

SIR.—The outbreaks of variola in this country in recent years represent a danger which should not be regarded as negligible in a population whose standard of vaccination is constantly declining. The number of contacts who develop the disease although vaccinated—or to the greater part revaccinated—at a time when successful vaccination, due to its shorter incubation period, should protect against the outbreak of variola is not very small. What is the reason?

I think that it will often be very difficult even for an experienced vaccinator to decide whether a small local reaction can be regarded as evidence of successful revaccination. How much more so in the case of many practitioners who had little opportunity to acquire the necessary experience with revaccination. It is, therefore, very likely that those contacts who developed variola under the above-mentioned conditions have been revaccinated unsuccessfully.

I should like to mention a point in my own personal experience. During my own medical career I have been in contact with variola patients on a number of occasions, and I have been revaccinated about ten times. Only once, many years ago, a very slight papular reaction made it rather likely that vaccination was successful. On all the other occasions the evidence was at least very doubtful. The last time this happened was in the third year of the last war. About two years later I inoculated myself from pure curiosity with the contents of a vesicle of a primarily vaccinated child, and I developed a large and very typical vesicle which would have given an excellent

textbook illustration for the effect of primary vaccination. Also the clinical course was only slightly shorter than that of primary vaccination.

This proves again the well-known fact that, especially in the case of revaccination, much better results can be expected from the use of human lymph as compared with calf lymph. The use of human lymph has practically been abandoned because of the danger of transferring syphilis, erysipelas, and other infections. But nowadays syphilis can be easily excluded by serological examination, and penicillin and the sulphonamides have greatly diminished the danger of septic infections.

Under these circumstances might it not be quite reasonable to use human lymph, if available, instead of calf lymph in such persons who as contacts are in immediate danger of developing variola and becoming themselves again a focus of further spread?—I am, etc.,

London, N.W.1.

G. FRIEDLAENDER.

### Physical Therapy of Mental Disorder

SIR,—The numerous letters you have published recently and in 1946 on physical therapy in mental disease indicate the interest the profession takes in the subject, and many of the general public show considerable interest also. In my letter in the *Journal* of March 23, 1946 (p. 447), I suggested proof of the efficacy of this treatment should be the percentage of recoveries on admissions in the report of the Board of Control. The report for 1945 was issued some time ago, and the recovery rate for that year was 33.2%—males 28.1% and females 36.7%—of the direct admissions, or slightly less than in 1939. The recovery rate for many years has been practically stationary.

The percentage of cases discharged as relieved has, however, risen considerably, the combined number of recovered and relieved being 63%, compared with 48% before the Mental Treatment Act of 1930. In their comments the Board state, "It is difficult to say whether the increased discharge rate is due to improved treatment or to the large number of voluntary admissions." It will be noted it is an increased discharge, not recovery, rate that reference is made to, and at least one popular paper seems to have confused the two. In 1945 the voluntary, temporary, and certified admissions were 50.7, 4.1, and 45.2% respectively. In 1934 the voluntary admissions were 29%. In 1945 the number of voluntary patients discharged as relieved was 5,872, as compared with 2,672 certified, the recoveries being 4,900 and 4,544 respectively. Possibly shortage of staff and beds may have contributed to the relieved discharges.

The stationary recovery discharge rate does not necessarily imply that E.C.T., leptazol, etc., are not of some use. Owing to the advanced average age of the community more senile admissions may have taken place; also there are fewer admissions of recent alcoholic psychoses, the latter a favourable type as regards prognosis. A good many Service patients may have been treated with or without convulsion therapy, and recovered, in places outside the jurisdiction of the Board of Control, and possibly the same applies to a number of civilians. Nevertheless the stationary rate in the mental hospitals does tend to show that the treatment may not be so efficacious as many consider.

In your issue of April 6, 1946 (p. 548), you published a letter from Dr. Ian Skottowe in which he stated that in 1945 the "useful discharge" rate for the Bucks Mental Hospital was 63.4%, or, excluding those over 60, 57.8%, and that E.C.T. was used in not more than half a dozen cases. He did not state the separate percentages of recovered and relieved, but his results seem to compare favourably with those obtained in hospitals where E.C.T. is extensively used, and may be regarded as a useful control experiment. In any form of therapy in mental disease it may be said—it is more or less a platitude—that the better the original make-up of the patient the better the results. The best results with E.C.T. are with the affective psychoses, especially involution melancholia—i.e., where there is no dementia, and where the nerve cells, unlike those in dementia praecox, are durable. If those involution cases associated with arteriosclerosis, etc., are excluded a certain amount of depression at the involution age might be regarded as normal, and some cases of melancholia are merely exaggerations of this. Further, a person having no mental attack until that age must have had a better brain than one breaking down at 20, except perhaps in some cases that have had no severe environmental stress.

Half a century ago Bevan Lewis and Clouston in their textbook gave a 50 to 60% recovery rate in climacteric insanity. We know, however, that a number of involution cases go on to severe agitation,

with distressing delusions, and if in fact E.C.T. prevents this it is indeed a boon. One would like, however, to see statistical proof.

In 1937 two medical commissioners of the Board of Control were instructed to visit Vienna, Budapest, and Frankfurt, also some English hospitals, to study treatment by leptazol and insulin, and their interesting report was published in 1938. I suggest that the time has now come when the Board of Control, the R.M.P.A., or the B.M.A. should appoint a body to make an exhaustive investigation into modern methods of treatment of the insane. So much E.C.T., etc., has been given in British hospitals that there would be no need to visit the Continent, where no doubt the ravages of war have seriously hampered treatment, but a visit to America might be of much use. Even if a satisfactory explanation of the mechanisms of these treatments cannot yet be given—and I understand anoxaemia is held by many to be the explanation in convulsive therapy—a comprehensive report would be of great value.—I am, etc.,

Hastings.

HARVEY BAIRD.

### Sulphone Treatment of Leprosy

SIR,—A considerable amount of attention is being given to the question of the treatment of leprosy by means of the derivatives of diaminodiphenyl sulphone, and once again there is a tendency for treatment to receive precedence over prevention. In view of the fact that I started leprosy work some twenty-three years ago at a time when the enthusiasm for the hydnoecarpus (chaulmoogra) derivatives was reaching its height and when responsible authorities stated that leprosy should be eliminated from the Empire within thirty years, I think it might be well if I sounded a warning note. It would be a tragedy if errors of the past were repeated and a belief encouraged that the leprosy problem could be solved by curative measures alone.

Leprosy has its roots in the dim ages and has a disconcerting habit of confounding those who would be over-optimistic. The past twenty-five years are strewn with the results of alleged cures. It therefore would be wise for us to remember this and not publicize too widely a new hope. If we do, administrative authorities may once again find themselves thwarted when they had high expectations that the problem had become easy of solution. Further, we tend to forget the psychological effect on the patients, for those who have severe lepromatous leprosy clutch at a new remedy as a drowning man would grasp at a straw.

We have been using these new preparations in India for the past year or eighteen months, and the following is a brief summary of our preliminary findings:

"Promin."—This substance is too toxic for ordinary use, and patients, in India at any rate, tend to show intolerance after some months.

"Diasone."—In the dosage recommended it is very liable to set up lepra reactions, frequently extremely severe. Fourteen out of twenty-two cases showed such reactions, and five of these fourteen asked that diasone should be discontinued. The reactions could not be attributed to the usual course of the disease, for regular records of the number of reactions and the interval between the reactions before the administration of diasone had been kept. We found, however, that adequate blood levels (5 mg. %) were impossible to maintain.

"Sulphetrone."—This remedy is not likely to be on the market for a considerable time. It is the least toxic of the sulphone preparations and has up to now caused no serious reactions. Further the levels of the drug in the blood were satisfactory. Sulphetrone in our opinion, has not been used over a long enough period for definite conclusions to be drawn. All that can be said at present is that workers are encouraged by the clinical improvement in lepromatous leprosy.

In conclusion I should like to emphasize the following points:

(1) The present methods of administration are not practicable of application on an extensive scale, except in institutions where patients are well regimented or sufficiently keen to be prepared to swallow these drugs in varying amounts, from three capsules of diasone to twelve tablets of sulphetrone per day, for long periods (2-4 years).

(2) These drugs should not be used without adequate blood level estimations. Regular blood counts and haemoglobin

estimations are not sufficient. A tendency to take lightly possible toxic effects may end in disaster.

(3) Failure, disappointment, or completely unreliable conclusions are likely to be drawn if used on cases other than the straightforward lepromatous type. It is to be remembered that the minority of the cases of leprosy in most countries are lepromatous.

(4) Even though the diaminodiphenyl sulphone derivatives proved to be effective in lepromatous leprosy, which is everyone's sincere hope, the leprosy problem would not be solved. It is essential to a better understanding of the disease that pathological studies, especially in connexion with cellular reactions in the skin, and epidemiological surveys should be continued. A proper appreciation of preventive measures, both with regard to infection as well as to the correction and prevention of deformities, is equally important. To reduce the problem of leprosy merely to one of therapeutics is to invite disaster and disillusionment.—I am, etc.,

London, N.I.

ROBERT G. COCHRANE.

### Gastrectomy and Gall-bladder Disease

SIR,—Drs. C. L. H. Majoor and Th. J. J. Suren (July 5, p. 8) postulate a possible relationship between subtotal gastrectomy and gall-bladder disease appearing subsequent to the operation. A relationship is known to exist between hiatus hernia and gall-bladder disease, and Bockus states that of all the complications of hiatus hernia gall-bladder disease and peptic ulceration occur most commonly.

Might I suggest that similar factors act in the production of cholecystitis (and, later, cholelithiasis) with both these entities? Points of similarity that spring to my mind are: (1) In both hiatus hernia and the post-gastrectomy stomach one has a reduced stomach volume, if one uses the herniated portion in the former for purposes of comparison. (2) Both conditions subject the oesophagus, stomach, duodenum, and jejunum to abnormal degrees of tension and reduce external mobility, and this may in turn lead to distortion of the biliary system. (3) Ecchymosis and mucosal disruption are common to both conditions—in subtotal gastrectomy at the time of operation and in hiatus hernia where strangulation exists or is imminent.

Other comparisons can be made with regard to blood supply, innervation, and emptying times in each. Whatever the causal or contributory relationship each has to the onset of cholecystitis and cholelithiasis, the immediate moral would appear to me to be that surgeons, after removing our stomachs, should leave us with a combination of viscera less closely simulating that seen in hiatus hernia.—I am, etc.,

Beckenham, Kent.

BRYAN WILLIAMS.

Bockus, H. L., *Gastro-enterology*, Philadelphia, Saunders, 1944, Vol. I, p. 158.

### Bornholm Disease

SIR,—Sir Humphry Rolleston<sup>1</sup> describes in the *British Encyclopaedia of Medical Practice* the condition variously known as Bornholm disease, epidemic myalgia, or acute epidemic myositis. It is a disease of the later summer months, more common in patients under the age of puberty, and is apparently transmissible (by a virus not yet isolated) by direct contact, with an incubation period of 2–4 days. It is characterized by pain—specially associated with respiration—whose onset may be very sudden, commonly in the upper abdomen, also experienced in the pectoral muscles and in the back. Slight fever is constant, vomiting is rare. Headache and hiccough are also said to be features. It was previously described on the Danish island of Bornholm, but has also been reported (*inter alia*) in Holland, N. America, and this country by Pickles<sup>2</sup> in 1933. It runs its course in a week and the prognosis is good. Treatment is symptomatic.

The two cases described here appear to fit in in spite of the fact that headache and hiccough were not prominent features. They were seen in a north-east country practice. Pickles<sup>2</sup> discusses the diagnosis of this condition and states that three useful points are (1) the almost invariable absence of vomiting, (2) increased respiratory rate, (3) rarity or absence of cough. He also mentions intervals of well-being between attacks of the muscle pain. Weterings,<sup>4</sup> describing Dutch cases, stated

that symptoms tended to pass off in 24 hours, often returning on the third day. These features are found in my two cases, which at first presented a diagnostic puzzle in which acute abdomen, lobar pneumonia, and pleurisy had at some stage to be excluded, but the absence of cough or vomiting, and the fact that there was probably a common cause of the two sisters' condition, led to the conclusion that they were cases of Bornholm disease. I have not seen any other cases to my knowledge.

#### CASE HISTORIES

*Case 1.*—An otherwise healthy girl from a good home, aged 9 years. Previous history, nil of significance. Chicken-pox and whooping-cough in infancy, and tonsils and adenoids removed three years ago. She was first seen early on the morning of May 31, 1947, having been awake most of the night with epigastric pain and pain in the right shoulder. Bowels had been regularly opened till May 30. There had been no vomit or cough and no sore throat or coryzal symptoms. The previous day she had been walking a lot on stilts and her parents thought the unaccustomed exercise had strained her muscles.

On examination temperature was 99° F. (37.2° C.), pulse 96, and respirations 24. Tongue furred white. No abnormality was detected in nasopharynx, chest, or abdomen. No rash seen. By the evening her temperature had risen to 100° F. (37.8° C.), pulse was 120, and respirations 32 per minute. She complained that the pain was catching her breath, and the movement of the right base was diminished, but apart from fainter breath sounds at this location no abnormal physical signs could be detected in the chest or abdomen. There was still no cough or sickness.

Next day, June 1, the temperature, pulse, and respirations were normal, and the pains had diminished. On June 2 temperature was normal, pulse 96, respirations 36. Respirations were laboured and she complained of pain in the back catching her breath. No abnormal physical signs could be elicited. She was treated with an acetosalicylic mixture and made a good recovery. When seen four days later she had no complaints and has remained well since.

*Case 2.*—The older sister of Case 1, aged 12 years, had come in from tennis on May 31 complaining of pains across the front of her chest, which were thought little of owing to her apparent good health and the exercise she had just undergone. The weather was warm at this time, it should be said. Two days later, however, she complained of pains in the chest and left shoulder and upper abdomen and felt feverish. Her temperature was 99° F. and never seemed to exceed this during the ensuing days. She had no cough or sore throat, no sickness, and the bowels were regular. No urinary symptoms were complained of, but there was some malaise.

No abnormality could be detected in the chest or abdomen, and the throat was clear. (Previous history very similar to her sister's and not significant.)

She was also treated symptomatically, and with an acetosalicylic acid mixture. Her pains disappeared, and in four days' time she appeared to have recovered completely and has continued well since.

The two girls had been away with their parents for the week-end before they fell ill. Their movements were: May 22, Corbridge (Northumberland) to Bolton (night stop); May 23, 24, and 25, at Colwyn Bay; May 26, night at Bolton again; and from May 27 on they were back at home in Corbridge. Although the incubation period mentioned by Rolleston is 2–4 days, and the week-end at Colwyn Bay and the night at Bolton would therefore seem to be exempted as the dates of infection, it would be interesting to know if other cases have been seen in those districts lately, as otherwise the source(s) of infection remain a complete mystery.—I am, etc.,

Corbridge, Northumberland.

A. MCE. TURNBULL.

### Training a Psychiatrist

SIR,—From the recent vitriolic correspondence which the article of Dr. D. W. Winnicott (May 17, p. 688) provoked a point emerges of more general significance than the merits or demerits of physical treatment in mental disorder, and that is the almost fanatical bias of the writers. This is a time of transition for medicine and especially for psychological medicine, and nothing retards progress more than failure to examine a problem with

a perfectly open mind. The dispute is analogous to that which raged and still rages round the Freudian school.

Closely related to such breadth of outlook is the question of the training and experience of would-be specialists in psychological medicine. Such experience should include residence in a mental hospital for at least two years, two years' experience as a certifying officer in mental deficiency, and a minimum of five years in a busy general practice (with obstetric experience). After such training one finds that on entering consulting practice as a psychiatrist one's experience dovetails to give a very different conception of the patient and his problem than would otherwise have been the case.—I am, etc.,

London, W.1.

R. M. AYTON-ORMSTON.

### Occupational Disease in Review

SIR,—The attention of the Departmental Committee on Industrial Diseases has been drawn to the leading article in the *Journal* of May 17 (p. 685) entitled "Occupational Disease in Review." The Committee welcomes the attention which the *B.M.J.* is giving to this subject but is concerned that the article should have failed to reproduce accurately its terms of reference, especially in regard to the phrase "to advise on the selection of diseases." It is feared that this may mislead some of your readers who may be in a position to give very valuable assistance to us in our work. The phrase might imply that the Committee has to recommend individual diseases for insurance. In actual fact it has to advise on "the principles which should govern the selection of diseases for insurance"—a task which involves careful reconsideration of the Samuel Committee's tests, but does not necessitate consideration of individual diseases except in so far as they represent questions of principle. The Committee's full terms of reference are:

"To review, in the light of modern industrial conditions, the policy adopted in scheduling diseases as industrial diseases under the Workmen's Compensation Acts, and to advise as to the principles which should govern the selection of diseases for insurance under the National Insurance (Industrial Injuries) Act, having regard to the extended system of insurance to be set up by the National Insurance Act and any other relevant considerations."

The Committee would appreciate evidence or suggestions from any persons or bodies interested in its task, who are asked to communicate with me. I shall be glad to supply an explanatory memorandum which has been prepared by the Committee, on request.—I am, etc.,

London, W.1.

F. K. FORRESTER,  
Secretary, Departmental Committee  
on Industrial Diseases.

### Remuneration in the N.H.S.

SIR,—The patient who waits until he is ill, possibly at 3 a.m., before presenting his medical card for inclusion in one's list annoys, as also does his reply to one's subsequent query: "Oh, I didn't bother about it, as I wasn't ill." No amount of knowledge of payments from a central pool serves to eradicate the feeling that the man's capitation fee for the last, say, three years could have been one's own. As Dr. W. W. Newton anticipates (p. 21, p. 902), the annoyance is likely to be greater and more materially felt after the appointed day. I do not agree with Dr. Newton's suggestion of introducing penalties to operate against those who fail to register with us. For one thing we as a profession do not wish to be party to penalizing our patients. The problem of the patient who is not on a doctor's list, or is on the list of the wrong doctor—i.e., after change of residence—is likely to be a serious one when the whole population is involved.

I would suggest that strong reminders be sent out to all who have not chosen a doctor within three months of the inception of the N.H.S., coupled with a warning that unless a doctor is chosen by the end of six months the patient will be allotted to a doctor, who may not necessarily be the one of his or her choice. (A rotation method fair to all doctors in an area could be easily devised.) As only a proportion of patients would be involved, doctors could probably stand a time-lag of six months without suffering financial hardship.

To avoid the central pool system and to ensure (a) that the doctor receives the capitation fees to which he is entitled and of which he has hitherto (on the N.H.S.) been deprived owing to defection on the part of the patient, and (b) that the doctor does not receive capitation fees relating to patients that have removed out of his

district, I suggest that, at whatever time a medical card is presented to the doctor, his entitlement to capitation fee is reckoned from (1) the commencement of operation of the N.H.S., (2) the commencement of entitlement to treatment, or (3) the date of taking up residence in that doctor's area, whichever is appropriate, the date being taken to the subsequent quarter day.

Thus, in the case of a patient who moves from A to B and then delays a year before presenting his medical card to the doctor at B this doctor would receive one year's capitation fee, which sum would be deducted from the doctor at A, with whom the patient was formerly registered, but who for the last year was not in a position to render treatment.

I agree with Dr. Newton that everything should be done to publicize the necessity for the patients' timely action, but it is of no use to expect perfection or anything like it. One has only to ask one's patients to-day if they have read the instructions on their medical cards. The answer gives little promise, even though the card is headed "Please read carefully."—I am, etc.,

Beer, Devon.

S. J. HADFIELD.

### Filling in the Health Act

SIR,—Section 28 of the *National Health Act* has not received the attention it deserves. It should be called the National Health Charter. It enables the local authorities to launch schemes for prevention, care, and after-care of disease. A little reflection will show that the scope of this section is infinite in its possibilities. Local authorities must submit schemes to the Minister by Nov. 30, 1947. Here is a chance for all health enthusiasts to push forward any progressive ideas they may have. It is quite certain that the Minister will approve any reasonable scheme.

Unfortunately there is no sign as yet that much attention is being paid to this invaluable section. People are so steeped in the past that they cannot make a leap into the future. A certain important body has sent me some suggestions. Among them the following seven points appeal to me:

(1) Establishment and supervision for special industrial premises for categories of persons who could do certain types of work under proper supervised conditions (mentioned by the Minister in Committee C when replying to a question on mental patients). (2) Night sanatoria (referred to by the Minister in Committee C). (3) Local rehabilitation committees, acting with representatives of the Ministry of Labour, voluntary organizations, etc. (4) Homes for unmarried mothers. (5) Care of elderly persons, including recreational centres. (6) Periodic health examinations. (7) Bureau for health advice.

These are just a few of the possibilities that open out. In conclusion it is hoped that the schemes suggested will not be final, that an opening will be left in the scheme for additions in the light of experience.—I am, etc.,

Southampton.

E. SAKOSCHANSKY.

### International System of Weights and Measures

SIR,—I agree with much of what Mr. H. V. Stopes-Roe says in a rather recondite way in his letter (June 28, p. 950), and I have dealt with some of his relevant points, explicitly or implicitly, and rather more simply, in my article on the International System of Weights and Measures (April 5, p. 460). The litre is an arbitrary and independent unit, or, as Mr. Stopes-Roe puts it, "a unit in its own right," and if he likes to consider it as a mere stage towards a fundamental unit, he must nevertheless accept the fact that the litre has no derivative or cognate relationship with the cubic centimetre: each is completely independent of the other. Of course a volume relationship between the litre and the cubic centimetre can be established, but this relationship is purely empirical and can be ascertained only by an empirical method—the method of determination by experiment. I explained this in my article, and I gave the factors which enable this empirical relationship to be expressed in terms of one or other of the units.

I should like to have been able to go more fully into general meteorological considerations which interest Mr. Stopes-Roe (and me also), but my task was a narrow one; it was to set forth as concisely as possible the essential features of one system of weights and measures—the international system—and it was this only that I endeavoured to do.—I am, etc.,

London, W.14.

J. M. HAMILL.

# HAY FEVER

*can be readily relieved  
by the application of...*

## 'ENDRINE' BRAND REGD NASAL COMPOUND

The application of a few drops of 'Endrine' into each nostril will soothe inflamed mucous membrane and effectively relieve the discomfort of hay-fever and the rhinitis of summer colds.

'Endrine' Ordinary formula: Ephedrine 0.75% w/w, Menthol 0.5%, Camphor 0.5%, Eucalyptol 0.5%, Oleum Ricini 0.35%, Light Liquid Paraffin ad. qs. 100%.

Available in 2 Varieties  
'ENDRINE' (BUFF LABEL)  
'ENDRINE' MILD (GREEN LABEL)

JOHN WATSON & SONS LTD. LONDON

## SUPPORT WITH COMFORT

Abdominal Ptosis in all its forms can be reliably treated by the Curtis Abdominal Support No. 1. It gives direct anterior-posterior pressure but has no undue constricting effect on the lower abdomen and assures complete freedom of hip movement; in other words, it gives gentle pressure and firm support *only* where it is needed. Lasting comfort in wear is assured at all times by the high standard of workmanship and finish. This is one of the many types of Curtis Products, whose use is recommended by the Medical Profession.

**CURTIS** MODEL No. 1  
ABDOMINAL SUPPORT  
K.T.M.

H. E. CURTIS & SON, LTD.

## 24-HOUR CONTROL

The characteristics of 'Wellcome' Globin Insulin (with Zinc) are adapted to the physiological needs of the patient—maximal effect during the day, diminishing effect during the night. This improved type of modified insulin (developed in The Wellcome Research Laboratories, Tuckahoe, New York) is available in strengths of 40 and 80 units per c.c., each in 5 c.c. phials.

Literature available on request

## 'WELLCOME' BRAND GLOBIN INSULIN (with Zinc)

BURROUGHS WELLCOME & CO.  
(THE WELLCOME FOUNDATION LTD.)  
LONDON

## THE MALE CLIMACTERIC ♂

Climacteric symptoms occur in men as in women, the result of decreased function of the sex glands.

The symptoms are as effectively relieved by Androgenic as are those of women by Oestrogenic therapy.

Carcinoma of the prostate is the chief contra-indication.

The use of sex hormones to increase sexual potency is often disappointing and should be avoided.

Testosterone Organon (Neo-Hombreol) is available in base form in 15 mg. suppositories; as a propionate in 5, 10 and 25 mg. ampoules and by mouth as Methyl Testosterone (Neo-Hombreol (M)) in 5 mg. mucosets. References and abstracts on request.

## TESTOSTERONE

### For dual spasmolysis

TRADE **PLACADOL** MARK

A new antispasmodic for both oral and parenteral administration.

Each tablet combines the musculotropic activity of papaverine hydrochloride (60mgm.) with the neurotropic properties of homatropine methyl-bromide (1.5 mgm.). For the relief of all spastic conditions of smooth muscle. Also available in 2 c.c. ampoules.

### And Introducing PLACADOL SED

Each tablet combines the dual spasmolytic activity of PLACADOL with the valuable sedative properties of codeine phosphate (10 mgm.). For the treatment of the more painful spastic conditions of smooth muscle, particularly in post-operative cases accompanied by coughing.

Information on these and other "WB" products sent on request.

## POINTS FROM LETTERS

## Shortage of Nurses

SURGEON LIEUTENANT, R.N.V.R., writes: I wish to dissociate myself most strongly from the views expressed in the letter of "Ex-Q.A.R.N.N.S.R." (June 21, p. 903). Her sweeping and totally unjustified attack will be resented by a great number of patients, doctors, and Naval nursing sisters. The V.A.D. has done and is continuing to do a very good job of work. Having recently been in charge of a ward staffed by V.A.D.s I should like to bear witness to their not inconsiderable nursing skill and devotion to what is often a thankless job. The standard of nursing in any ward depends to a large extent upon the example and training given by those in charge, and for any lowering of that standard the sister must be held partly to blame. The educational and cultural level of the average V.A.D. compares very favourably with that of the first-year nurses whom I examined for the General Nursing Council. V.A.D.s often enrolled with the idea of making nursing a permanent career, but many have since been disillusioned, and such hasty and ill-conceived criticism and evaluation of their work may deter many others.

Miss Doris C. HUGHES (Leamington Spa) writes: With reference to the letter of "Ex-Q.A.R.N.N.S.R." (June 21, p. 903), as a V.A.D. with 64 years' service in the Navy I should like to point out: (1) I have received no encouragement whatsoever to take my training, and moreover when I applied to train at a well-known midland hospital in 1941 I was told, at an interview with the matron, that I was more use as a V.A.D. (2) At a sick quarters on the East Coast, where the staff was small and casualties frequently being admitted, V.A.D.s did all the dressings and assisted M.O.s with the cleaning up of wounds and burns in the dressing-room. There was a separate zymotic block in which we "specialised" cerebrospinal meningitis cases, nasal diphtheria with scalded throats—in fact, any fever case placed on the D.C.L. (3) Temperatures and medicines were always entrusted to a responsible V.A.D., and several sisters for whom I worked said that a capable V.A.D. was quite as competent as many S.R.N.s. I could cite several examples of "fingers instead of forceps" used by sisters. Many of my colleagues were so disheartened by their treatment with some sisters that any desire to train was crushed. If closer co-operation and less professional "jealousy" existed between S.R.N.s and V.A.D.s there would be many more nurses available now.

## Land of Excuses

Dr. G. C. PETHER (Colchester) writes: Dr. Bruce Williamson (June 28, p. 950) suggests that as a profession we failed to persuade the public to improve conditions of feeding, sanitation, and health. He then suggests that the public, sensing our neglect, has chosen to saddle us with a State service. I feel that this approach is unfair. Doctors know quite well that health comes largely from good houses built at reasonable cost, good food produced at a fair price and sold under hygienic conditions. Why should we, as a profession, be blamed for bricklayers who only lay 300 bricks a day and plumbers who are so incompetent that their pipes burst in winter? Why should we be blamed for the insane expenditure on films, greyhounds, drink, and tobacco? Why should we, who with the housewives work an eighty-hour week, be blamed by those whose contribution to the country's recovery is to work half this time? I resent very keenly the suggestion that these things are our fault. The country gets the politicians it deserves, and few of them have the courage to stress what I write here. Doctors have very little to do with health and our opinions on the matters described have been well known for years. If people will not listen it is not our fault. In conclusion many of us honestly believe that increasing interference by the State, which has neither soul to be damned nor body to be kicked, will aggravate many of our troubles. Let the plumbers and bricklayers get on with the job of promoting better health, and let their value in this matter be properly explained to them. Many houses built by the State are rotten.

## Euphoriant for Depression

Dr. MARGARET A. QUINE (Torquay) writes: I wish to congratulate Dr. G. Tayleur Stockings on his able and illuminating work (June 28, p. 918) on the relief of depression through the medium of the euphorizing drug synhexyl. In this work, however, there seems to me something much more far-reaching than the empiric dose—this is the link he furnishes between mood and metabolism. Other illnesses that have a definite "affect" tone in addition to a demonstrable lesion in the brain are disseminated sclerosis, with its early facility; Kinnier Wilson's hepato-lenticular degeneration; subacute combined, with its depression; and in G.P.I. the grandiose euphoria or depression. Three at least of these are known to have frank disease or dysfunction of the liver. Is it not possible that before long we shall prove that the ancients were right in believing the liver to be the seat of the soul?

## Obituary

JOHN THOMSON MACCURDY, M.A., M.D., Sc.D.

Dr. J. T. MacCurdy died on July 1 after a brief illness. For some years he had occupied the position of Lecturer in Psychopathology at Cambridge, but his standing in psychiatry rests more upon his writings and his work in the war than on his lecturing, which did not absorb much of his time. His early experience in psychiatry was obtained in Canada and the United States. In Canada he took his B.A. in biology at Toronto University in 1908, and after attending the famous courses at the Johns Hopkins University, where he proceeded M.D. in 1911, he continued his studies in Germany. He then returned to a fellowship at Johns Hopkins and later lectured at Cornell University. In the war of 1914-18 he passed from the Psychiatric Institute of New York to the American Army, in which he held the rank of captain in the Medical Corps.

He came to England in 1922 after his election to the Presidency of the American Psychopathological Association. From then Cambridge became his home, and in 1926 he became a Fellow of Corpus Christi College, where he spent most of the rest of his life. He was always an esteemed member of this College, both for his high intellectual qualities and for his social attributes, which played a large part in his interesting personality. His contributions to psychology, although not widely known, display a discriminating mind and a fine philosophical attitude towards a subject which can so easily become a happy hunting ground for the dilettante and the indiscriminating. His book *The Psychology of Emotion* broke new ground as well as sounding a firm critical note of then existing theories; although time has proved his criticisms and views were not always tenable, his honesty of purpose was transparent. He followed this later in *Common Principles in Psychology and Physiology*. He attempted to explore the no-man's-land between the two disciplines where so many acrimonious battles have been fought. In his book *Mind and Money*, published in 1933, with both daring and wit he handed economics over to the applied psychologists; and later, during the last war, his volume entitled *The Structure of Morale* exhibited a deep knowledge of current affairs and an equally shrewd insight into national character. During the war he did much work on psychological warfare, assisting Government Departments, aiding the B.B.C. in their efforts to undermine German morale, and devising tests for the R.A.F. He looked forward to a time when the Army Council would have a psychiatrist on its Board, who would influence the conduct of war not merely by suggestions but almost in framing a war policy. That he did not succeed was not his fault. While Army psychiatry achieved much in many unexpected fields, MacCurdy's hopes could not be achieved in his time. Prejudice dies hard, particularly where concepts about human behaviour are concerned.

Dr. MacCurdy was a big-framed, athletic-looking man, though giving an impression of indolence. But under his apparent façade of cynical inaction there resided a deep thinker who preferred clear concepts to therapeutic adventures. He married in 1914 Winifred, daughter of Mr. David B. Jones, of Chicago, and leaves a son and a daughter.

Dr. FRANCIS ELLIOT FOX, who died on April 27, was medical superintendent of Brislington House, Bristol, a private mental hospital which has been owned and administered by his family for several generations. His father, Dr. Bonville Fox, died when Francis Elliot was a boy, and the succession from father to son was further delayed by service in the 1914-18 war. On leaving Winchester F. E. Fox joined the Army, where he reached the rank of captain. While stationed in Persia towards the end of the war he received grave head injuries, but he made a good recovery and was able in 1919 to begin the study of medicine at Cambridge. From Caius College he went to the London Hospital and qualified in 1924. After holding a clinical assistantship at the London and a house appointment at the Bethlem Royal Hospital, he was for a time assistant medical officer at Peckham House before he returned to Bristol to take up the work for which he had trained. In 1940 he published in the *British Medical Journal* a paper describing his clinical

experience with electrically induced convulsions. A man of fine presence and kindly bearing, "Sonny" Fox (as he was affectionately called by his many friends) was capable in both professional and public affairs. He was a member of the Bristol city council and for many years chairman of the Frome Conservative and Unionist Association. His chief hobby was gardening, and at Brislington House he made a beautiful garden even more beautiful. He married in 1941 Ethel Mary Skuse, who survives him with one son.

Mr. ALFRED ERNEST MAYLARD died at his home in Peebles on June 27 at the age of 93. Mr. Maylard was well known in Glasgow, where he was associated with the Victoria Infirmary from 1890. Mr. Maylard was a student at Guy's Hospital, where he was one of the demonstrators in anatomy in the early 'eighties. He was a fellow of the Royal Faculty of Physicians and Surgeons and of the Royal Society of Edinburgh. Mr. Maylard will be remembered as a general surgeon with a particular interest in the surgery of the abdomen. On his retirement in 1919 from the post of visiting surgeon at the Victoria Infirmary he was appointed honorary consulting surgeon and elected to the board of governors. His interest in this work was actively maintained until 1933. His principal recreations were walking and mountaineering, and he was at one time president of the Scottish Mountaineering Club. He had been a member of the British Medical Association for 64 years.

We announce with regret the death at the age of 86 of Lieutenant-Colonel W. T. Frederick Davies, C.M.G., D.S.O., a former President of the South African Medical Council. William Thomas Frederick Davies received his medical education at Guy's Hospital, London. He qualified M.R.C.S. in 1882, and took the M.B.Lond. in 1883 and the B.S. in 1884, proceeding to the M.D. in 1887. He served in the South African War as Surgeon-Major to the Imperial Light Horse in 1899-1900, when he was awarded the D.S.O. He commanded the 2nd Imperial Light Horse in 1914-15 in South-West Africa and was wounded. He served in the R.A.M.C. in 1917-19, and was appointed surgeon specialist to the General Military Hospital at Colchester. Dr. Davies was Vice-President of the Witwatersrand Branch of the B.M.A. in 1921 and President of the Transvaal Medical Council in 1925. He was elected a member of the South African Medical Council in 1928. He was honorary consulting surgeon to the Johannesburg Hospital.

The death of Dr. HERBERT HENRY MILLS, after only three days of acute illness, removes one who was possibly the doyen of Kensington practitioners, for he started in practice there over fifty years ago and was at work right up to the time of his last illness. He was born at Peterborough in 1868, and after attending the grammar school in that city won a scholarship to University College School. Thence he entered the school of medicine at Westminster Hospital, and he qualified in 1891 as M.R.C.S., L.R.C.P., taking his M.D.Lond. in 1896; in his final year he had been awarded the prize in clinical medicine. He was house-physician and later assistant demonstrator in anatomy at his own hospital. Mills came into prominence at the time of the controversies aroused by the National Health Insurance Act of 1911, when his downright support of the Lloyd George scheme brought him into antagonism with the policy approved by the Representative Meeting of the B.M.A., from which body he resigned in that year after 8 years membership; however, the animosities then aroused died down, and in 1928 he rejoined the Association. He served on the Advisory Committee created under the Act, and on the London Insurance Committee. For many years he was Medical Referee to the Prudential Assurance Company. He was a Fellow of the Medical Society of London, of which he had been a council member; and served as president of the West London Medico-Chirurgical Society in 1931-2. He married Miss Ernestine Evans Bell, who survives him, together with their only child, Dr. Hermia Mills, now working at Aylesbury.

Dr. FRANCIS MARTIN BERNARD DOUGHERTY died recently at the early age of 40. He qualified M.B., Ch.B. in Capetown in 1930, and took the B.Hy. and D.P.H. of Durham in 1938. He was senior resident medical officer of the Royal Victoria Infirmary, Newcastle-on-Tyne, and District Medical Officer of Richmond, Natal. Dr. Dougherty was also assistant medical officer of health to the Surrey County Council, a post he gave up in 1940 when he returned to South Africa to enter the Army Medical Service there. In 1943 he became second in command of No. 2 S.A. Convalescent Depot in Italy. In 1945 he resumed practice in South Africa at Howick. He is survived by his widow and one son.

## Medico-Legal

### RECOMMENDATION AS A MEDICINE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

By the Pharmacy and Medicines Act, 1941, if a person sells by retail any article recommended as a medicine the article or its container must be labelled with the appropriate designation and quantities of its ingredients. A "substance recommended as a medicine" may only be sold by a doctor, a dentist, an authorized seller of poisons, or a person who has served a regular apprenticeship to a registered pharmacist. It is closely defined by the Act as a substance which is referred to on the label, or on a placard in the shop, or in an advertisement, in terms which are calculated to lead to its use for the prevention or treatment of any ailment, infirmity, or injury affecting the human body, but which do not give a definite indication that the substance is intended to be used as a food or drink and not as a medicine.

Messrs. Potter and Clarke, manufacturing chemists, asked the opinion of the High Court in a friendly action against the Pharmaceutical Society on whether a specified series of common laxatives with specified labels were "substances recommended as a medicine." The label on senna pods merely gave the name and the name and address of the firm. Their cascara was labelled "Trade Mark: Winged Lion Brand. Fluid Extract of Cascara Sagrada. British Pharmacopoeia. Dose, half to one teaspoonful in half a wineglass of water." Lemon and squill linctus was merely labelled with its name and the name and address of the firm. Compound rhubarb pills also bore the name and the dose. "Effervescing Powders" was labelled "Extra strong Effervescing Powders. Prepared by Carter and Sons, Sheffield, a wartime substitute for Seidlitz Powders Carters," with instructions for use and the manufacturer's address. The firm maintained that these medicines, so labelled were not "substances recommended as a medicine" and so could lawfully be sold by unqualified persons. Mr. Justice Wynn-Parry held that they were right in regard to the senna pods and the linctus but not in regard to the other substances presumably because the dosage was specified.

The firm appealed, arguing that the written terms must specify the particular ailment or groups of ailments for the prevention or treatment of which the substance is appropriate. The Pharmaceutical Society argued that this was not necessary if it was common knowledge that the substance was in fact used for the prevention or treatment of a specific ailment or group of ailments. For example, the label on the cascara though it did not mention constipation, might be nevertheless calculated to lead to the use of fluid extract of cascara sagrada for the prevention or the treatment of constipation. The same, they said, applied to the rhubarb pills and the seidlitz powder substitute: both were well-known household remedies.

The Court of Appeal held that the relevant words of the Act were neither doubtful nor ambiguous. They did not think that Parliament would have desired to make the criminal liability of a seller of medicine depend on the accuracy of his speculation concerning the exact extent to which the general public knows that a particular medicine is a remedy for a particular ailment. If the written terms contain only an accurate description of the substance it is not "recommended." To render it "recommended" its description must indicate that it is a remedy for a specified ailment. They therefore held that the three laxatives in question could, with the given labels, be sold by unqualified persons.

1947 1 All E.R. 802.

The Hebrew medical journal, *Harofé Haivri*, the first number of which appeared in 1927, celebrates its twentieth anniversary in the current number. It is published in New York and written in Hebrew and English. General articles on Jewish culture and medical terminology in Hebrew are usually included in the journal, and in addition the present number contains articles on streptomycin, anticoagulant therapy in thrombosis, and narco-analysis.

\* With commendation.

## Medical Notes in Parliament

### Penicillin

On July 7 the House of Lords agreed to the Commons' amendments to the Penicillin Bill.

### Noxious Fumes

On July 8 Mr. SOMERVILLE HASTINGS asked the Minister of Town and Country Planning when he expected to be able to report the result of his investigations into the elimination of harmful and unpleasant products from the gases produced by oil-fired furnaces.

In replying Mr. SILKIN recalled that a month previously he said he was satisfied from advice received that sulphur and other noxious fumes could be eliminated, but that to ensure that the design of the necessary plant was satisfactory a pilot gas-washing plant was to be constructed. This plant had now been designed. Construction would take six months to complete. The results of this experiment should be available in about a year.

### Ministry of National Insurance Posts

Mr. JAMES GRIFFITHS announced on July 8 that an invitation to apply for posts in the Ministry of National Insurance would, he hoped, be issued within the next fortnight to all full-time approved society staffs wholly or mainly engaged on National Health Insurance work. There would, however, be vacancies in his Department for others with suitable experience. He expected to be ready to advertise in the early autumn for applications from such persons.

### Merging Service Medical Branches

Cmdr. NOBLE on July 9 asked the Minister of Defence what progress had been made towards merging the three Service medical branches.

Mr. ALEXANDER, in reply, said this question was still under examination. It had not yet been established that the complete merger of the three medical services was to be preferred to the alternative of the maximum degree of co-ordination between those services.

Col. STODDART-SCOTT asserted that the merger of these services would result in great economy in military manpower. He asked Mr. Alexander also to consider the merging of the three nursing services.

Mr. Alexander said that he himself and the other Departments which had examined the subject had so far not been convinced of the economies to be achieved. The matter, as he had already said, was still under consideration.

### Regional Hospital Boards

Col. STODDART-SCOTT on July 9 asked the Prime Minister to set up a Select Committee to consider the effect on the hospital services of the appointment to regional hospital boards of M.P.s from one side only of the House of Commons, although members of other parties had similar qualifications in hospital work, administration, and management.

Mr. ATTLEE replied that he repudiated the suggestion that these appointments were political. He said that examination of the boards' membership would prove that persons with suitable experience had been chosen without any shadow of political exclusiveness. The question of setting up a Select Committee therefore did not arise.

Col. Stoddart-Scott said that four members of the Commons, all of Mr. Attlee's Party, and four members of the House of Lords, none of whom was a Conservative, had been chosen to sit on these boards. Such political appointments, he predicted, would make changes in the hospital boards inevitable after the next general election and would be to the detriment of the hospital service.

Mr. Attlee then said that Col. Stoddart-Scott's facts were not correct. He believed that on these boards were five M.P.s from the Government side of the House. From the House of Lords there were Lord Cunliffe, the Earl of Cranbrook, and Lord Henley, who were certainly not members of the Labour Party. There was also Lord Eustace Percy, an eminent Conservative. It was unjustifiable to complain that, after so many years, some Labour people were appointed to these various boards.

Sir HENRY MORRIS-JONES asserted that some of the names on these boards, particularly in North Wales, had been received with perplexity. He asked why the names of well-known people who had given their lives to hospital service were omitted.

Mr. Attlee suggested that perhaps they were too old.

Mr. GORONWY ROBERTS asked on July 10 what was the procedure followed in appointing regional hospital boards; and whether Mr. Bevan was satisfied that an adequate proportion of suitable women representatives were being appointed to these boards.

Mr. BEVAN replied that the boards had been appointed after consulting all the principal organizations and bodies concerned. The object had been to select the persons of best experience and qualification for the task, not representatives as such. However, the answer to the latter part of the question was in the affirmative.

Mr. GORONWY ROBERTS asked on July 10 how many appointments had been made to the Welsh Regional Hospitals Board; whether this number was fixed; and what procedure would be followed in filling casual vacancies.

Mr. BEVAN answered that a chairman and 31 other members had been appointed in accordance with the constitution laid down in the National Health Service (Constitution of Regional Hospital Boards) Order of June 24. Casual vacancies would be filled by the Minister of Health after consultation with the board and with any other bodies which appeared to be concerned.

Major LEGGE-BOURKE inquired why, in view of there being two isolation hospitals and two general hospitals in the Isle of Ely, no member from the Isle of Ely had been appointed to serve on the East Anglian Regional Hospital Board.

Mr. BEVAN replied that though every effort had been made to secure a reasonable balance of local knowledge on this and other boards, they were not intended to be constituted on a basis representative of particular areas or interests.

### Temporary Registration

On July 10 Mr. JANNER asked the Minister of Health what was to be done to assist doctors and pharmacists with foreign qualifications who were on the temporary *Register* and who would be unable to continue to practise when temporary registration came to an end in December next.

Mr. BEVAN announced that the Government would seek the approval of Parliament to legislate on this subject. It intended to introduce a Bill before the end of the session, although it could not be passed during the session, in order to make the detailed proposals fully known as soon as possible. He hoped there would be general agreement with them.

### Calf Lymph

A question put by Mr. HOBSON on July 10 asked whether the lymph used in vaccination against smallpox was still manufactured in the skins of animals; and whether the calves used for the production of lymph at the Lister Institute were slaughtered before the lymph was extracted.

Mr. BEVAN said that the answer to both parts of the question was "Yes," except that sheep and not calves were used by the Institute.

**Nutrition.**—The proportion of school children examined in England and Wales whose nutritional state was classified as bad was 0.5% in 1939 and 0.3% in 1943 and 1945. The figure for 1946 is not available.

**Milk for Schools.**—At the end of last year 93.8% of the school milk to grant-aided schools was heat-treated or tuberculin-tested. Where neither of these types is at present supplied the Ministry of Food is endeavouring to arrange, in co-operation with medical officers of health, that they shall be.

**Double Day Shifts.**—Mr. Isaacs stated recently that the Government was not satisfied that it was necessary to retain in full the present legal obstacles to adoption of the double day-shift system, provided that proper protection was afforded for the health and welfare of persons employed on that system.

**Additional Bread.**—Mr. Strachey regretted that he could not extend to hospital cleaners or workers with similar duties the additional bread ration coupons to which nurses were already entitled.

**Disabled Unemployed.**—A count is taken each month of the number of disabled persons recorded at employment exchanges as unemployed. On May 19 last the number was 64,754. Special steps are taken to put disabled applicants in touch with suitable employment or to give them vocational training if that is required. For the severely disabled special provision is made by the Factories of the Disabled Persons Employment Corporation.

**Financial Benefits.**—In framing the National Assistance Bill Mr. James Griffiths will consider sympathetically the inclusion of a provision that financial help to be given in respect of any disease over and above the benefits payable under the National Insurance Act, shall not be confined solely to cases where recovery is probable.

## E.S.T.P. — the improved Tar Preparation

BRAND (MARTINDALE) Ether Soluble Tar Paste  
Purified, decolorised, non-staining, aromatic; maximum Tar effect

FORMULA  
Ether Soluble Tar Distillate .. 1.5% Starch .. 12.0%  
Zinc Oxide .. 14.0% In a special emollient base.

A smooth paste easily applied. The tar component retains the essential phenolic compounds unimpaired, ensuring powerful antiseptic action. All indications for Tar Treatment are indications for "E.S.T.P." (Martindale), more especially infantile eczema; eczema generally; impetigo complicating eczema; prurigo; pruritus; psoriasis; pityriasis circinata; lichen planus. In 2 oz. and 16 oz. pots.

Sample and Literature on request.

W. MARTINDALE, Manufacturing Chemists  
75, New Cavendish St., London, W.1

## ELIXIR SIBEC

is indicated in  
HAY FEVER, BRONCHITIS  
and BRONCHIAL ASTHMA

A WELL BALANCED PRESCRIPTION  
OF THE IODIDES OF CAFFEIN  
WITH EPHEDRINE

THIS COMBINATION HAS RECEIVED

## ANAHÆMIN B.D.H.

*The Dakin and West*

*Erythropoietic Fraction of Liver*

Clinical experience over a decade has established that the administration of Anahæmin B.D.H. constitutes a most effective form of treatment of pernicious anæmia.

Anahæmin B.D.H. produces, with small and comparatively infrequent doses, a prompt and satisfactory erythropoiesis in patients in relapse, it ensures the maintenance of a normal erythrocyte level in patients in remission and is effective in preventing the onset of subacute combined degeneration of the cord. Further information is available on request.

MICRO-CRYSTALLINE HORMONES

## OESTRONE

and

## TESTOSTERONE

FOR

### SUSTAINED ACTION

Unlike hormone solutions, suspensions of hormone crystals are absorbed slowly and their effect is thereby enhanced and protracted. Micryston Oestrone is thus rational in oestrogenic deficiency and Micryston Testosterone in testicular deficiencies. As, in many cases, one weekly injection produces a sustained flow of hormone, a great economy of material and effort is attained.

ISSUED IN VIALS OF 8 C.C.  
Oestrone 1 mg. per c.c. Testosterone 2 mg. per c.c.  
Scientific literature on request.

Sole Distributors for U.K. and Dominions.

## Nutritional Supplement and Digestant

# 'TAKA-BEXIN'

### CAPSULES

Each 'Taka-Boxin' Capsule contains:—

Taka-Diastase	...	1 gr.
Vitamin B <sub>1</sub> (Anourine Hydrochloride)	...	1 mgm.
Vitamin B <sub>2</sub> (Riboflavin)	...	1 mgm.
Vitamin B <sub>6</sub> (Pyridoxine Hydrochloride)	...	0.5 mgm.
Pantothenic Acid	...	0.15 mgm.
Nicotinamide	...	6 mgm.
Vitamin C (Ascorbic Acid)	...	15 mgm.

Indicated in anorexia, polyneuritis, pregnancy and lactation, febrile illnesses, hyperthyroidism, restricted diets and convalescence. Particularly useful in elderly patients and in those who need assistance in digesting the starchy food predominant in present-day diets.

Supplied in bottles of 50 capsules.

**Parke, Davis & Company**

## EPIDEMIOLOGICAL NOTES

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 28.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## Smallpox

At Bilston M.B. the diagnosis in a boy aged 10 removed on July 3 has now been confirmed. Modified rash appeared on July 2. He had been vaccinated for the first time on June 23. Contacts are still under surveillance.

The first case at Willenhall U.D., adjacent to Bilston, was removed on July 9. She is aged 19 and unvaccinated. She sickened on July 3 and a confluent rash appeared on July 6. Numerous contacts are under surveillance.

At Barnsley C.B. the daughter and son-in-law of the 62-year-old woman admitted to the smallpox hospital on June 30 were removed on July 11, when smallpox rashes appeared. Both had been vaccinated on July 2, one primarily and the other after an interval of 30 years.

The suspected case removed from the *Carnarvon Castle* on her arrival at Southampton on July 8 is suffering from chicken-pox. There is no smallpox in Southampton.

Up to July 12 there had been 10 cases of smallpox in two generations in Calais, and one in Lille secondary to the focus in Calais.

## Anterior Poliomyelitis

The Registrar-General's returns for the week ending July 5 record 79 notifications (9 in corresponding week of 1946). This figure has been exceeded on only very few occasions since the disease became notifiable in 1912. The maximum recorded incidence was in 1938 (1,489 cases), and in the first 27 weeks of that year 127 cases were notified. The figures for the corresponding periods of 1946 and 1947 have been 206 and 435 respectively (uncorrected).

The disease is widely spread. Notifications in the week ending July 5 were received in 65 sanitary districts and were mainly singletons. However, since July 5 multiple cases have been reported from several districts. An unprecedented prevalence is to be expected.

Acute onsets with marked meningeal reactions leading to a diagnosis of meningitis or meningo-encephalitis appear to have been a feature in the present outbreak. In such cases the pre-paralytic stage lasts some days, and it may be presumed that infectivity is greatest in this period. Early isolation on suspicion before there is any evidence of paralysis is probably the most effective action towards preventing the spread of the disease. Bulbar and respiratory paralysis are unduly frequent, and respirators are in demand.

In one extra-metropolitan borough 7 children have been admitted to the isolation hospital since June 18, 5 of them in the first eleven days of July. Two required treatment in respirators. Tonsillectomy was performed on one of them, aged 4, fourteen days before paralysis of the bulbar type appeared. It has been advised that when poliomyelitis is prevalent nose and throat operations should be postponed whenever possible.

## Cerebrospinal Fever

A rise in cerebrospinal fever notifications contrary to the expected seasonal decline may be an expression of the increased incidence of anterior poliomyelitis with marked meningeal signs at onset. The figures for the week ending July 5 were 64.

## Bubonic Plague in East Prussia

A report has been received that epidemic bubonic plague appeared in Königsberg during June and has inflicted an extremely serious mortality among the civilian population.

## Food-poisoning

An outbreak of food-poisoning caused by *Salmonella typhimurium* has occurred at Lincoln. Thirty-three cases have been reported, including one death. The faeces of 16 were examined; the organism was demonstrated in 15. Infection occurred from some salami sausage served at a dinner at which 77 people sat down on July 5. Investigations into the source of the contamination are proceeding.

Nine cases of typhoid are reported at Rattlesden, Suffolk. Three households are involved. Two further suspected cases are under observation. The source of the infection was contaminated lettuces from a local supply. The probable carrier is being investigated.

Nine cases of food poisoning have been reported from Winchester, and further suspected cases are being investigated. The causative organism is one of the salmonella group.

## Typhus in London

A case of murine typhus is reported from Bermondsey, London. The patient, who has now recovered, was a man

employed in unpacking crates of eggs from Poland. Flea-bites were discovered on his body. He had never been abroad. There have been no further cases.

### Discussion of Table

In *England and Wales* there was a decreased incidence of measles 1,255, whooping-cough 55, diphtheria 38, and an increased incidence of scarlet fever 77, dysentery 19, cerebrospinal fever 18, and poliomyelitis 12.

Large decreases in the notifications of measles were reported from London 198, Kent 171, Essex 148, Staffordshire 132, Derbyshire 117, while the only increase of any size was that in Yorkshire West Riding 71. No large variations from the total of the preceding weeks were recorded in the local returns of scarlet fever. The only changes of any size in the local incidence of whooping-cough were decreases in London 88, and Lancashire 41. The chief feature of the diphtheria returns was a decrease in Lancashire of 12 cases and in London of 9.

A new outbreak of dysentery was reported from Surrey, where the number of cases rose from 0 to 28, the chief centre of infection being Leatherhead U.D., where 21 cases were notified.

The two cases of smallpox were notified from Staffordshire, Bilston M.B. 1 and Willenhall U.D. 1. Another death, the fifth, from smallpox has been recorded at Bilston; the latest victim was an unvaccinated boy aged seven.

The number of cases of cerebrospinal fever notified rose after declining for three weeks; the 57 notifications involved 20 counties. For the fourth consecutive week an increase was reported in the notifications of acute poliomyelitis; the 56 cases were distributed through 18 counties.

In *Scotland* only small changes occurred in the incidence of infectious diseases with the exception of acute primary pneumonia, cases of which decreased by 34. In the eastern area the notifications of diphtheria increased from 2 to 9.

In *Northern Ireland* there were decreases of measles 18 and whooping-cough 10.

In *Eire* the notifications of diarrhoea and enteritis increased by 17; 46 of the 56 cases were reported from Dublin C.B. Increased notifications were also recorded for whooping-cough 19 and diphtheria 7. The rise in whooping-cough was mainly due to an outbreak in Mayo, Claremorris R.D.

### Infectious Diseases During the Half-year

The returns of the infectious diseases for the first half of 1947 show that, generally, the incidence was below the average. The notifications of diphtheria were the lowest ever-recorded and were less than half of the number in the corresponding period of last year. The notifications of scarlet fever have shown a progressive decline and were only about half of the total for four years earlier. Cerebrospinal fever was more prevalent, and more cases were notified than in the preceding three half-years. The total incidence of dysentery cases was slightly more than one-quarter of the preceding half-year. The notifications for the first six months of 1943-7 in England and Wales were:

	1943	1944	1945	1946	1947
Scarlet fever .. ..	50,544	48,654	36,302	30,910	27,423
Whooping-cough ..	50,302	56,488	33,687	45,592	53,791
Diphtheria .. ..	19,154	15,978	12,032	10,882	5,393
Measles .. ..	347,687	52,622	412,843	59,818	302,299
Acute pneumonia ..	28,442	24,499	21,472	24,078	22,555
Cerebrospinal fever ..	2,203	1,851	1,691	1,662	1,959
Dysentery .. ..	3,002	5,669	10,006	6,703	1,763
Shifoid and paratyphoid ..	358	247	259	250	248
Great towns:					
No. of births .. ..	169,924	186,651	174,276	206,638	259,060
No. of deaths .. ..	124,090	128,656	132,693	138,955	154,657
Infant mortality .. ..	59	54	58	51	52
Case fatality per cent:					
Scarlet fever .. ..	0.16	0.15	0.17	0.10	0.12
Whooping-cough ..	1.25	1.21	1.33	0.90	1.37
Diphtheria .. ..	4.2	3.0	2.7	2.6	2.0
Measles .. ..	0.25	0.14	0.19	0.17	0.21

A large increase occurred in the number of births and deaths during the first half of 1947 in the great towns compared with the experience of preceding years. Not only has the incidence of diphtheria decreased but an improvement has also been recorded in the case fatality.

### Week Ending July 5

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 966, whooping-cough 2,240, diphtheria 188, measles 10,269, acute pneumonia 353, cerebrospinal fever 64, acute poliomyelitis 79, dysentery 57, smallpox 3, paratyphoid 8, typhoid 15.

## Medical News

### Assistant Editor, B.M.J.

An advertisement appears in this issue for a Medical Assistant Editor to the *British Medical Journal*. The salary scale is £1,000 to £1,875 a year. The appointment may attract those who combine with literary or journalistic ability an interest in medical science. There is no prescribed age limit, and youth should not deter anyone from putting in an application.

### Vitamin Tablets for Mothers

From Aug. 1 every mother will be entitled to free vitamin A and D tablets for 30 weeks after the birth of her child at the rate of one packet each 6 weeks. She will receive coupons for the tablets when she notifies the food office of the birth. The tablets will be distributed through the food offices and maternity and child welfare centres. Mothers with babies under 30 weeks old on Aug. 1 should apply to their local food office, taking their own and their babies' ration books with them.

### Oliver Memorial Fund

The trustees of the Oliver Memorial Fund will make their first award of £50 to a British subject whose original work is considered to have made the most notable contribution to the subject of blood transfusion in the last five years. The committee welcomes applications, or information drawing their attention to suitable candidates. Correspondence, with a brief summary of such work, should be sent to F. W. Mills, Esq., National Provincial Bank, Ltd., Holborn Circus, London, E.C.1, before Oct. 1.

### Dr. Jessie Macgregor Prize

The Dr. Jessie Macgregor Prize in Medical Science will be awarded to the applicant who presents the best record of original work in the science of medicine, published or unpublished, but which must not have been published earlier than three years prior to July, 1947. The value of the prize is about £50, and it is open to medical women who are graduates in medicine of the University of Edinburgh, or who have taken the Scottish triple qualification, and who, before becoming qualified, have studied medicine for at least one year in Edinburgh. The successful applicant shall, within six months following the award, deliver a lecture to the medical profession in Edinburgh on the subject of the work for which the prize has been awarded, such lecture to be entitled "The Dr. Jessie Macgregor Lecture." Applications, marked "Dr. Jessie Macgregor Prize," must reach the convener of trustees, 9, Queen Street, Edinburgh, 2, not later than July 31.

### War Memorial Fund

The British Empire Nurses War Memorial Fund now stands at £45,791, £37,400 of which has been contributed by the nurses of the Commonwealth and Empire. At a meeting held in February the gift of two travelling scholarships, to the value of £350-£375 was announced, one from the Royal College of Physicians, through Lord Moran, the other from Viscountess Mountbatten of Burma. The Fund held a garden party at St. James's Palace on July 8 to pay tribute to the nurses and midwives for the part they played in the war and for their generous help to the Fund.

### Wills

Lieut.-Col. John du Plessis Langrishe, formerly lecturer in the Public Health Department of Edinburgh University, who died on Feb. 28, left £3,428 5s. 3d.

## COMING EVENTS

### Residential Summer Schools

The Central Council for Health Education will hold residential summer schools at Keble College, Oxford, from July 25 to Aug. 8, at an inclusive cost of £16 16s., and at Bede College, Durham, from Aug. 20 to Sept. 3, at an inclusive cost of £14 14s. Particulars may be obtained from the Medical Adviser and Secretary, Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1.

### Cystine and Protein Reaction

A meeting of the Polarographic Discussion Panel of the Society of Public Analysts and Other Analytical Chemists will be held at 3 p.m. on July 25 in the Chemistry Department, University College, Gower Street, London, W.C.1. Dr. R. Brdicka will deliver a lecture, of interest to medical men, on analytical applications of the cystine and protein reaction in biochemistry and medicine. Prof. J. Heyrovsky will discuss "New trends of polarographic analysis, differential and oscillographic."

**Banting Memorial Lecture**

Prof. Charles Best, F.R.S., will deliver the Banting Memorial Lecture under the auspices of the Diabetic Association on Friday, July 18, at 10.30 a.m. in the Medical School, King's College Hospital. The lecture will be followed by other lectures and demonstrations on the treatment of diabetes, on Friday afternoon, July 18, and Saturday morning, July 19. Medical men and students are invited to attend.

**Veneral Disease in N.H.S.**

The annual general meeting of the Medical Society for the Study of Veneral Diseases will be held at 11, Chandos Street, London, W., on Saturday, July 26, at 3 p.m., when a discussion on "Venereal Disease in the National Health Scheme" will be opened by Col. L. W. Harrison.

**Colour Vision**

The Colour Group of the Physical Society announces that a Conference on Colour Vision will be held at Cambridge from July 28 to Aug. 2. The provisional programme includes the following papers: Prof. S. L. Polyak (Chicago), "Retinal Structure and Colour Vision"; Prof. R. Granit (Stockholm), "Electrophysiology of the Retina"; Dr. D. L. McAdam (Rochester, N.Y.), "Colour and Brightness Discrimination"; Dr. W. S. Stiles (Teddington), "Fundamental Sensation Curves"; Dr. D. B. Judd (Washington), "Colour Blindness"; and a contribution by Prof. S. Hecht (New York). Further information may be obtained from Dr. E. N. Willmer, Physiological Laboratory, Cambridge, to whom all applications for tickets should be addressed.

**SOCIETIES AND LECTURES**

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Thursday, July 24, 6.15 p.m., Charles Tomes Lecture by Prof. E. Sprawson: Foods and Feeding as they Affect Teeth and their Environment.

KENT PAEDIATRIC SOCIETY.—At County Hospital, Farnborough. Saturday, July 26, 3 p.m. Prof. Lionel Penrose: Genetics in Relation to Paediatrics.

MEDICAL ART SOCIETY.—Exhibition at Royal Society of Medicine, 1, Wimpole Street, London, W., Thursday, July 17, to Saturday, July 26.

**POSTGRADUATE DIARY**

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, London, W.—Royal Hospital, Richmond, Surrey: Saturday, July 26, 9 a.m. to 5.30 p.m. One day course on the Diagnosis and Treatment of Varicose Veins. Open only to those holding Surgical Appointments. Dreadnought Hospital Greenwich S.E.: Saturday and Sunday, July 26 and 27. All-day week-end course in Medicine and Surgery.

INSTITUTE OF LARYNGOLOGY AND OTOLGY, 330, Gray's Inn Road, London, W.C.—Monday, July 21, 4.30 p.m. Mr. W. M. McIlison: The Nose, Nasopharynx and Paranasal Sinuses.

The Fellowship of Medicine announces: (1) A week-end course on chronic rheumatic diseases to be given at the Rheumatic Unit, St. Stephens Hospital, Fulham Road, S.W., on Saturday and Sunday, October 25 and 26. (2) A course of lectures on Anatomy, Physiology, Pathology, Bacteriology, and Pharmacology, for Primary F.R.C.S. candidates; to be given at the Lecture Room of the Royal Cancer Hospital, Fulham Road, S.W., on Mondays, Wednesdays and Fridays, from August 18 to October 24. All particulars from the Fellowship of Medicine, 1, Wimpole Street, London, W.

**BIRTHS, MARRIAGES, AND DEATHS**

The charge for an insertion under this head is 10s. 6d. for 15 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

**BIRTHS**

CONDIE.—On June 1, 1947, at Perth Royal Infirmary, to Martha Rennie (née Scott), wife of Dr. William Hall Condie, M.B., Ch.B., Schoolhouse, Kinnairds, Perth, a son. Both well.

HILL.—On July 4, 1947, at Dublin, to Dr. Nancy Hill (née Hinchcliff), wife of Dr. William J. C. Hill, Duncegan, Portrush, Northern Ireland, a daughter—Valerie Elizabeth.

MACARTNEY.—On July 7, 1947, at Crumppall Hospital, Manchester, to Joyce (née Worthington), wife of Dr. Donald W. Macartney, a son.

TAY.—On July 3, 1947, at Chesterfield, to the wife of Dr. A. P. Tait, a daughter.

TAYLOR.—On July 6, 1947, at Kirtler Nursing Home, Arbroath, to Dr. and Mrs. Taylor (Peggy Reid), Hyde Park House, Arbroath—a daughter.

**DEATHS**

ARMSTRONG.—On June 23, 1947, at 11, Sefton Drive, Liverpool, S. Hubert Armstrong, M.D.

BAKER.—On July 8, 1947, Helen Baker, M.D., D.P.M., wife of John Peterson, University House, Bethnal Green.

HUMER.—On June 25, 1947, suddenly, at George, South Africa, John Daniel Humer, O.B.E., F.R.C.S. Ed., beloved husband of Marjorie Harmer, of Langford, Kingswear, Devon.

O'MEARA.—On May 18, 1947, at Luton, Beds, Dr. Hubert O'Meara, M.B., B.S. Lond.

**Any Questions ?**

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

**Poliomyelitis and Water**

Q.—Is there any foundation for this statement recently published in a lay paper: "Current medical opinion is that acute anterior poliomyelitis is spread by contaminated water and the recent incidence is a result of the rise in level of ground water owing to heavy rains and the consequent pollution of unprotected water supplies by the virus"? An annotation in the British Medical Journal last year said that since the virus was demonstrated in faeces in 1940 it had focused attention on the importance of the four F's in its spread; but it did not stress the importance of water.

A.—There is no foundation for the suggestion that the recent occurrence of poliomyelitis is due to a rise in the level of ground water, since this infection has its greatest incidence in the autumn, when ground-water levels are ordinarily low. However, the virus of poliomyelitis is present in the faeces of typical and abortive cases during the acute and convalescent stages of the infection, and it has been recovered from the sewage of towns at the time when cases were occurring in that area. Some outbreaks have also shown a geographical relationship to water courses, so that the possibility that water from sewage-contaminated rivers and swimming-pools may be a vehicle for the spread of the virus cannot be gainsaid. When a case has occurred in a household, therefore, all the necessary precautions should be taken to prevent the spread of infection to food or drink by contaminated hands or flies. At the same time, there is a considerable body of evidence that infection is most often spread by direct contact, which may mean that droplets from the upper respiratory tract may also spread the disease. The virus can be demonstrated in the oropharynx during the acute stage, and it has lately been recovered from the throats of school-children in contact with a case. A high standard of personal hygiene in a household or semi-closed community where infection has appeared is therefore the most likely means of controlling spread of poliomyelitis.

**Vaccination against Smallpox**

Q.—What should be the frequency of vaccination in areas where smallpox is endemic? What interpretation as to the subject's immunity is to be given to the so-called "immune response"—that is, a fleeting papule appearing 48 to 72 hours after immunization?

A.—Revaccination every 10 to 12 months should be carried out in areas where smallpox is endemic. A fleeting papule 48 to 72 hours after vaccination with vaccine lymph merely indicates a previous contact with the antigen and may occur with dead virus. Thus it is probably only a "sensitivity" reaction and not an indication of immunity. It is considered safest to record "successful vaccination" only when a vesicle appears. It is interesting to note in this connexion that vaccination by the multiple pressure method has recently resulted in good takes in numerous individuals who had several unsuccessful vaccinations by the usual scratch method.

**Lisping**

Q.—A boy aged 6, of normal intelligence, has lisped since learning to speak. Should an effort be made to correct the defect now, or should it be left to right itself?

A.—In lisping (or dyslalia) there is a persistent impairment of enunciation of one or more consonants. Its causes and degree vary considerably. In this case local causes, such as a shortened fraenum linguae or a malformed palate, should be sought and treated, together with any other pathological states of the nose and throat not obviously connected with the trouble. If dyslalia persists after this, or if no such causes are found, treatment by a speech therapist should be given if

the defect is marked or if the child moves in an environment where clarity of speech is not observed. Children with mild lips moving among clear speakers tend to recover without treatment.

### Orchitis after Mumps

**Q.**—*As the result of severe orchitis following mumps a 52-year-old patient has become impotent. I have been giving him methyl testosterone sublingually, pushed to 45 mg. a day, without result. Can anything more be done?*

**A.**—Orchitis following mumps is an important cause of impotence, so much so that in the case of bilateral orchitis it is advocated that an incision of the capsule of the testis on one side should be made to relieve compression tension. If the procedure is carried out on both sides, and the attempt fails to prevent destruction of the interstitial cells, the surgeon might wrongly be blamed. The condition should have responded to the treatment given, but it may be that larger doses are required initially—for example, the injection of 25 mg. of testosterone daily. An alternative therapy is the subcutaneous implantation of 800 mg. of testosterone propionate.

### Oxygen Inhalation

**Q.**—*I have been told that the B.L.B. mask, under ideal conditions in a healthy subject, can produce an alveolar oxygen concentration of 96%. I believe there is also experimental evidence that concentrations of oxygen much above 60% cannot be breathed for more than a few hours without ill effects, such as pulmonary congestion and oedema. Are there any conditions in which oxygen would appear necessary but, given in this way, could be dangerous?*

**A.**—Inhalation of oxygen at a pressure of one atmosphere is said to produce symptoms of lung irritation in normal young men after about fourteen hours' exposure. The subjects complain of cough, sore throat, nasal congestion, and substernal pain. At or below concentrations of 60% the inhalation of oxygen is apparently harmless, but there is not complete agreement among clinical workers on this point. Actually it is difficult to get an alveolar oxygen concentration of anywhere near 95% with the usual type of B.L.B. mask unless all the ports can be closed, the mask is well fitted, and mouth-breathing prevented. The nasal mask may deliver from 40 to 95% oxygen according to circumstances. In general, oxygen is necessary to combat arterial anoxaemia or to hyperoxygenate the blood—that is, to carry oxygen in solution as well as combined with haemoglobin. It is probable that 100% oxygen can be safely given for short periods to all patients, but if it is necessary to continue for longer than twelve hours then the concentration should not exceed 50 to 60%, provided this is sufficient to oxygenate fully the arterial blood. If it is not, then the risk of continued anoxia must be balanced against that of a tracheo-bronchitis due to the use of oxygen.

### "Dyspeptic" Ulcers

**Q.**—*What is the best treatment for a woman of 50 who suffers from periodical crops of small ulcers on the inside of her cheeks? She has no dyspeptic symptoms.*

**A.**—So-called dyspeptic ulcers which appear in crops on the buccal mucous membrane are usually quite unconnected with dyspepsia, and the term is a misnomer. Bacteriological investigation, while often showing mixed oral types with no predominating organism, often reveals pneumococci and haemolytic streptococci. Apart from general measures, and vitamins A, B, etc., to ensure that the mucous membrane is in a healthy state, local measures should include general oral hygiene. The administration of penicillin in pastille form, which appears in some cases to get rid of the infection (MacGregor and Long, *Journal*, 1944, 2, 686), is worth a trial.

### Diphtheria and Vitamin B

**Q.**—*Is there any evidence that any of the B vitamins are useful in the treatment of the cardiac debility and paresis caused by diphtheria toxin?*

**A.**—There is no controlled evidence that any member of the vitamin B complex has a beneficial prophylactic or therapeutic effect on diphtheritic paralysis or on the cardiovascular compli-

cations of diphtheria (see this *Journal*, 1941, 1, 359). The administration of such vitamins in a debilitated patient may, however, produce a sense of well-being.

### Dehydrocholic Acid

**Q.**—*What is known about the therapeutic action of dehydrocholic acid?*

**A.**—Dehydrocholic acid is useful for its ability to increase the volume of the bile. It does not stimulate evacuation of the gall-bladder, but it may be of value to remove mucus or debris from the bile ducts. A copious flow of bile may flush the ducts but does not necessarily affect the gall-bladder. Dehydrocholic acid is contraindicated in complete mechanical biliary obstruction. The dose is 0.25 to 0.5 g. two or three times daily after meals for a period of four to six weeks.

### Metal-fume Fever

**Q.**—*Oxy-acetylene welders who inhale zinc oxide fume sometimes develop an acute characterised by sickness, general malaise, joint pains, and signs of general toxæmia. Is milk good antidote?*

**A.**—When galvanized metal is being welded the fume may contain zinc oxide, and unless the inhalation of this fume is prevented "metal-fume fever" with the characteristics described may occur. These effects are acute and transitory, with an onset some hours after inhaling the fumes; the views of Lehmann (*Arch. Hyg. Berl.*, 1910, 72, 358) on the pathology of the condition are still the accepted ones—namely, that the metal particles in the fume damage the epithelial cells of the lung alveoli, and that the ill effects are attributable to the absorption of proteins from these dead cells. It is clear from this that milk is not an antidote, and the general principles of treatment will be those of an acute infection. Prevention lies in ventilation which is adequate to remove and harmlessly dispose of fumes arising from welding and other operations which give rise to metal fume. Particular attention should be paid to ventilation when welding is performed in a confined space, as inside a boiler, tank, or compartment of a ship.

## NOTES AND COMMENTS

**Fissured Lip.**—Dr. F. F. HELLIER (Leeds) writes: The answer given to the question about fissured lips (July 5, p. 41) did not mention treating the cause of the condition. The most likely cause is ill-fitting dentures which produce a fold of skin at the corner of the mouth. This has been called pseudo-riboflavinosis because it somewhat resembles that caused by lack of riboflavin. The condition is cured by increasing the vertical dimension of the denture and filling it out a little so that the fold is eliminated. Obviously if there is a lack of vitamin B this should be corrected but this is a very uncommon cause in this country.

**Scabies Infection of Anus.**—Dr. J. G. DAVIES (Edinburgh) writes With reference to the answer under "Any Questions?" on the above subject (July 5, p. 41) I would like to make the following observations. In the Army in W. Africa and India scabies was regarded in the great majority of cases as being acquired by sexual intercourse. The distribution was different from that commonly observed in this country and the areas most frequently affected were the genitals and the buttocks. The fingers and wrists were comparatively rarely affected. I would suggest that the case occurring in Natal may have been acquired venereally, and the mention of urine as a possible means of spreading the infection tends to support my belief that in those cases of peri-anal involvement the penis may have been the original source of infection. In V.D. clinics in Britain, too, scabies mainly affecting the genital organs following sexual exposure is frequently seen.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 19 1947

## MEDICAL ORGANIZATION IN DENMARK PUBLIC HEALTH SERVICES

BY

E. JUEL HENNINGSSEN

*Chief Physician, National Health Service*

In the year 1740 Denmark acquired her first supreme medical board, the Collegium Medicum, "in order that everything in relation to hygiene and its improvement may be carried out in the best manner and according to the best knowledge and with the best conscience by means of a harmonious council." That board and its successor, the Royal Health College (which replaced the Collegium Medicum in 1803), both consisted of a chosen number of physicians who, without remuneration, placed their professional knowledge at the disposal of the nation as the supreme medico-legal authority, as medical advisers to the Government as that body might desire, and as head of the public health system. There was no lack of eminent and discerning members on these boards, but they had no real influence on the organization of the country's health service or the administrative status of the medical personnel by virtue of their position. However, notwithstanding their relatively unimportant standing, the boards were the driving force in passing a number of far-sighted laws.

An Ordinance of April 17, 1782, provided that during epidemics among the peasantry the cost of medical attendance and drugs was to be defrayed at public expense, and a Rescript of July 2, 1790, ordained that all cases of venereal disease (syphilis) were to be notified to the authorities and that "every one of the common people" suffering from this disease must undergo treatment, which he had the right to receive free of charge—a principle that has been preserved in our modern legislation, though nowadays the law applies to all and not merely the "common people." Our first quarantine law was given in the Ordinance of Feb. 18, 1805, and by the Ordinance of April 3, 1810, smallpox vaccination was introduced as a voluntary and free measure.

For the promotion of the treatment of disease it was laid down in a Royal Resolution of June 6, 1806, that a certain number of hospitals were to be erected in every county, primarily for venereal disease cases but also for those who were unable to get the necessary attendance in their homes. The cost of these hospitals was to be borne by counties and boroughs, as is the case to-day.

As a consequence of the experience gained during a cholera epidemic in 1853 an Act of Jan. 12, 1858, was passed by which all Danish towns were to have by-laws regulating public hygiene (sewerage, drinking water, dwellings, foodstuffs). Earlier legislation had provided only for Government measures, supervised and put into practice by the publicly employed medical officers; but the Health By-law Act meant that the local authorities acquired rights and obligations to concern themselves with important aspects of public health, a line still followed in Denmark's public health system to-day.

A characteristic feature of the close of last century was the interest taken in the care of the sick; and to make the necessary nursing and treatment at home or in a hospital available for everyone in the event of sickness our first Sick Club Act (1892) provided that sick club members were to receive medical attendance and hospital treatment free of charge, or at only very slight personal expense. These principles hold good in our health insurance to this day. The new developments engen-

dered the building of many new hospitals all over the country and the modernization of the old ones. Surgeons were appointed as principals to the hospitals, and the law compelled hospitals to allow the sick clubs a considerable reduction of the charge for treating members, the balance of the expense being defrayed by counties and boroughs.

In 1900 Denmark's first tuberculosis sanatorium was opened by the General Danish Medical Association, and 1901 saw the foundation of the National Society for the Combating of Tuberculosis as a private association. In 1905 Parliament legislated to provide Government support in the campaign against tuberculosis, including help to local authorities and private persons wishing to build and run hospitals and sanatoria.

### Public Health Reform

The rapid growth of the country's public health system made it increasingly necessary that the affairs of the health authorities and the medical personnel should be regulated by law. The Collegium was instructed to devise a medical system to replace the arrangement created by the famous Thomas Bartholin in 1672 to cover the work of the doctors, the apothecaries, and the midwives. However, it fell to the lot of neither the Collegium Medicum nor its successor, the Royal College of Health, to cope with that task. It was only as a result of the work of the Medical Commission, appointed in 1908, that it was possible to introduce a new statutory organization of these matters.

If the two colleges were unsuccessful in creating a new medical system it was due to no lack of initiative or brains on their part; nor was there a dearth of suggestions from the profession itself. Throughout its almost centenary existence the Royal College of Health took up the cudgels again and again, only to fail because of its lack of influence. It was only with the acceptance of parliamentary government in 1901 that the proper basis was established. The awakened interest of the politicians of the new system in working for social aims led to the appointment of a mixed commission, consisting of professional men (physicians) and Members of Parliament from all parties as representing the interests of the people. It was not difficult to convince that body that reform was not a matter of bowing to theoretical "medical demands" but of creating the best possible organization of the public health system in all its ramifications. A flourishing period for public health followed. The ancient laws on venereal diseases, on quarantine, and on fighting epidemics were revised. The activities of medical officers, midwives, and dental surgeons were regulated by law. The hospital system grew apace.

After 1932 the development in our hospital system began which has now reached such a stage that every county—apart from those with several hospitals of moderate size, all modern and directed by fully qualified surgeons—has at least one central hospital, with separate medical, surgical, and x-ray departments, some of them also with departments for other special branches. In 1933 came the Authorized Trained Nurses Act, and in 1934 Parliament passed a Physicians Act, the first since the old Ordinance of 1672 on Physicians and Apothecaries. In 1928 the building of tuberculosis dispensaries was started, and to-day they cover even the most remote parts of the country. By examining and controlling consumptives, school-children, workers in various trades, soldiers, etc., they contribute importantly towards protecting the healthy from tuberculosis.

With this a new phase in the history of Danish public health was initiated, a phase characterized by systematic work on a

legal basis, administered by State and local authorities in collaboration, for the purpose of preserving the health of the healthy. By the Infant Mortality Act of 1937 the State promises financial support to local authorities if they will employ public health nurses who, by visiting all homes within their area, well-to-do or poor, can advise mothers on the care of their babies. The number of local bodies employing public health nurses is growing steadily. During the second world war the country was menaced by a malignant form of diphtheria. A law was passed entitling every person up to the age of 18 to be vaccinated against this disease by a doctor free of charge. The Government paid the doctors for the operation.

Much legislation prepared during hostilities has been enacted since the war. Under the Pregnancy Hygiene Act of 1945 every pregnant woman has the right to three antenatal examinations by a doctor and up to seven by a midwife. The State bears the cost. An Act of April 30, 1946, provides that children of pre-school age (0-7) have the right, free of charge, to have up to nine supervisory examinations by a doctor, three of them in the first year of life. The cost is defrayed by State and local authority, each paying half. By an Act of July 12, 1946, every school—State, local council, or private—must supervise the health of its pupils through a school doctor and arrange regular health examinations. State and local authority bear the cost.

#### Place of General Practitioners

The principle introduced by these laws, as in diphtheria vaccination during the war, is that this new and important work is placed in the hands of the general practitioners, the people's usual physicians. The school doctors are chosen and appointed from among the local practitioners. This arrangement, which arose out of the important position held by Danish general practitioners, their high average standard and their intimate association with the people, opens up the question of the rational education of practising doctors with special reference to health control work. The settlement of this question is at present occupying the attention of the General Danish Medical Association and others.

One of the first results of the recommendations made by the medical commission was the creation in 1909 by Parliament of a central body, the National Health Service, which not only acted in an advisory capacity to the country's authorities but, by virtue of its structure and position within the administration, had every chance of initiating reforms in the country's public health services. A revision of the Act in 1932 ensured that the position of the National Health Service was adapted to the latest public health developments.

#### National Health Service

The activities of the National Health Service are threefold: advisory, supervisory, and administrative. The medico-legal work of the old colleges has been transferred to a special Medico-legal Council, which is independent of the National Health Service. The Service is chief adviser to the public—first and foremost to the central administration (the Ministries), which must hear the opinion of the N.H.S. in all matters requiring the expert insight of a medical man or a chemist—and also to other administrative authorities such as county and municipal councils. It must preserve close contact with health conditions in the country and see that health laws are observed: regulations are being neglected the responsible authorities are informed. The National Health Service must also submit suggestions for the improvement of public health whenever it considers them necessary. It should be mentioned in this connexion that it is one of its duties to inform and guide the people by means of publications and lectures on special health measures or special risks of disease.

The National Health Service is the chief supervisor of all hospitals, public or private, all nursing homes, children's homes, and homes for the aged; of all prisons and work-houses; and of all premises which, having regard to their nature and the purpose to which they are put, are subject to special health regulations. The head of the Service, or his deputy, therefore has access at all times to these premises. When hospitals or the other institutions referred to are to be erected or radically altered, the plans must be submitted to the Health

Service authorities for their opinion. Chemists' shops or drug stores are licensed, and the National Health Service draws up rules for their working, sanctions their premises, fixes the prices to be charged for the medicines sold there, and inspects and supervises them all.

All physicians, dentists, midwives, nurses, masseurs, and the like are under the National Health Service as regards their office and professional duties, and it can order them to send in such notifications and reports as may be required. The same applies to all proprietors of drug stores and to their assistants.

The National Health Service authorizes physicians and dentists to practise. As regards the former, the condition is that they take the medical degree at a Danish university and put in a year's service as assistant at a hospital approved by the Health Service for the purpose. For dentists the condition is the examination set by the Copenhagen School of Dentistry and two years' service with a qualified dentist.

No physician may call himself a specialist or practise as such unless he has gone through special training and thereafter received authorization from the National Health Service as a specialist. Midwives are authorized by the School of Midwives in Copenhagen. No one may practise as a physician, dentist, or midwife without authority. Nursing is not restricted to specially trained nurses, but nurses who have done three years' training at a hospital approved by the National Health Service as a training hospital are authorized as trained nurses and only such nurses are employed in public health posts.

Administratively the National Health Service comes under the Ministry for Home Affairs, which is responsible for its annual estimate. This, however, does not affect it in its aforesaid capacity of chief adviser on health questions to the various Government departments, with which it corresponds and communicates directly.

#### Director of the Service

The Director of the National Health Service, who is appointed by the Crown, must be a physician. The Service consists of two departments and a secretariat. The Hygiene-Medical Department employs a number of physicians with special training as advisers, and also a general practitioner and a dentist. The advisers with special professional knowledge as well as the practising physician and dentist are selected from among the leading specialists in their own particular sphere. They all perform this advisory work while continuing their actual duties as professors, chief physicians at hospitals, private practitioners, whereby they represent a constantly free connexion between the National Health Service, medical research, and practical medicine.

The Director is responsible for handling matters dealt with by the Hygiene-Medical Department and obtaining the necessary expert advice. This, however, does not include matters respecting recommendations to administrative hospital authorities on appointments to leading medical positions in the hospitals or the filling of other vacancies in the public service. Such matters are dealt with by the National Health Service Medical Council, which consists of the aforementioned advisers and the Director, with the latter as chairman. Nor does his responsibility extend to matters concerned with depriving physicians, dentists, midwives, etc., of the right to practise; such matters are decided by a special council consisting of the Director, the practitioner attached to the Service as adviser (physician, dentist, or midwife as the case may be), and at least one member of the Medical Council.

The Director is chairman of the Board of Housing Inspection, of the National Health Service Food Committee, and of the Medical Veterinary Committee, which forms a connecting link with the Directorate of Veterinary Affairs.

#### Laboratories in the Service

In the Pharmacy Department a pharmacist is chief and he is assisted by a graduated pharmacist working at a chemist's shop. Matters in this department are decided not on the responsibility of the Director alone but by him in conjunction with the two pharmaceutically trained officials. In this department there are three specially qualified pharmacists who, together with the county medical officers, make an annual visit of inspection

to the chemists' shops, and analyse in the Control Laboratory of the National Health Service medical and other samples taken on their rounds. The Control Laboratory also has an analyst for testing proprietary medicines sold in the country.

Under the National Health Service, but working independently, there is a special committee consisting of medical and pharmaceutical experts whose task it is to draw up and revise the *Pharmacopoeia Danica* and to make recommendations to the National Health Service concerning proprietary medicines. In addition to the pharmaceutical control laboratory the following institutions and laboratories are associated with the National Health Service: (1) The State Serum Institute, a large institution doing both practical and purely scientific work. It manufactures sera and vaccines and is also the central epidemiological research laboratory for the entire country. It undertakes many other diagnostic investigations, among which are various blood tests for syphilis and the more special bacteriological tuberculosis tests. (2) The Institute of General Hygiene Research, which also draws up diet regulations for hospitals and other public institutions. (3) The State Vitamin Laboratory, which analyses foods advertised for their vitamin content as well as therapeutic vitamin preparations.

The medical officers of health are directly under the N.H.S. In every county there are a county medical officer and two or three district medical officers. To become an M.O.H. a doctor must go through a special course of training and pass an examination in public health. Medical officers represent the N.H.S. *vis-à-vis* the local authorities, and within his district each one is engaged on advisory, supervisory, and administrative work similar to that of the N.H.S. The local authorities must consult the M.O.H. on all matters requiring medical insight. He takes an active part in the fighting of epidemic and venereal diseases and tuberculosis. One of his duties is to collect the medical statistical material. As a member of the local Epidemic and Health Committees (see below) he shares in decisions on many questions of hygiene dealt with by these committees.

### Local Ownership of Hospitals

The administration of public health in Denmark rests almost exclusively on central and local authorities, who also bear most of the expense incurred. Only a few hospitals are owned and run by private societies and religious bodies. The local councils elect health committees. The M.O.H. is a member, and their object is to see that the health by-laws are observed and keep an eye on sanitation within their area (drinking water, sewerage, foodstuffs, dwellings, cemeteries, etc.). An epidemic committee takes the local action against epidemic diseases delegated to it by the Epidemic Act. The local authorities direct the campaign against venereal diseases. Tuberculosis dispensaries and hospitals are built and conducted by them, though the State bears half the running expenses.

The hospitals are mainly run by the local councils, and all are erected and owned by the local authorities—as was decided by Royal Resolution as long ago as 1806, and there is no doubt that a factor of great importance to the development of the Danish hospital system is that the local population have always been the owners of these institutions and through their elected representatives have influenced their building, rebuilding, and working.

The public health nurse service and the school doctor service are in the hands of the local bodies, but the State shares the cost. Most of the mental diseases hospitals and one or two hospitals and maternity homes come under the State. Occupational hygiene is in the hands of a Government directorate with specially appointed doctors.

Thus, whereas only a small part of the public health administration is directly in the hands of the central Government, the latter's various departments handle and decide many matters that are often of vital importance to public health and its future development. Practically every Ministerial department is concerned with matters relating to public health. It will be sufficient here to note our social legislation and the importance of the national sickness, accident, and invalidity insurance scheme. The N.H.S.'s central advisory position within the central administration, and its contact with all Ministries

whenever they deal with affairs of health, stand out as being particularly significant on this background.

It might seem as if decentralization so pronounced as that outlined above would make the health work in a country difficult. In actual fact, however, the results achieved in Denmark under this system are equal to the best in the world in the prevention of disease and the promotion of health. Everything indicates that the system suits the people's mentality, political system, and cultural status. There seems to be no obvious reason for departing from the line hitherto followed, harmonizing as it does with the fundamental characteristics of the people.

## ANNUAL REPRESENTATIVE MEETING, 1947

### FURTHER MOTIONS AND AMENDMENTS FROM DIVISIONS

#### PRELIMINARY

#### *Priority Supplies of Milk to Invalids*

**Motion by CITY:** That this meeting protests against the order of the Ministry of Food instructing local food offices to insist on the renewal of milk priority certificates with the issue of new ration books even where these certificates have been given just prior to the new issue. This order throws extra work on already overburdened doctors.

#### *Ex-Service Practitioners*

**Motion by BELFAST:** That, with reference to para. 10 of the Council's Report, this meeting requests the Council to make special representation on behalf of ex-Service doctors in Northern Ireland with a view to the establishment of a postgraduate scheme for ex-Service practitioners in that country, as under the Government Act of 1920 the Northern Ireland Government is precluded from making grants specifically for the training of ex-Service graduates.

#### NATIONAL HEALTH SERVICE ACT

#### *Statutory Bodies under the Act*

**Motion by CITY:** That this meeting demands that general practitioner representation must be assured on the various statutory committees and councils set up under the Act, with particular reference to Regional Hospital Boards, Hospital Management Committees, and the Health Committees of Local Health Authorities.

**Motion by CLEVELAND:** That this meeting views with alarm the situation that has arisen over the appointments to the Regional Hospital Boards, where nominations put forward—at the request of the Minister—and elected by regular ballot, have not been accepted.

**Motion by WEST SUFFOLK:** That the Council be instructed to press for adequate representation of the medical profession on Regional Hospital Boards.

#### *Report of Negotiating Committee*

**Motion by BRONLEY:** That this meeting is profoundly disturbed at the secrecy which surrounds the negotiations at present in progress, and requests early information on the position up to date.

#### *Whole-time Medical Officers employed by Central, Regional, or Local Authorities*

**Motion by HENDON:** That the Ministry of Health be informed that the Representative Body is of the opinion that all whole-time medical officers employed by the central, regional, or local authorities should have a right of appeal to a suitably appointed committee when an appointment has been determined on grounds that reflect adversely on a practitioner's professional reputation or procedure.

#### *Group Practice*

**Motion by CITY:** That the inclusion of women and children in a 24-hour service will throw a heavy strain on doctors under the Act. This meeting therefore recommends that grouping of doctors be encouraged in the interests of general practitioners and their patients.

#### GENERAL PRACTICE

#### *Fees for Medical Examination in connexion with Life Insurance*

**Amendment by CLEVELAND:** That for the words in lines 14-16, "where he is required to carry out a domiciliary examination an additional fee of 5s. should be paid," there be substituted "where

he is required to carry out domiciliary examination an additional fee of one guinea should be paid."

#### Telephone Facilities for Doctors

Motion by WEST SUFFOLK: That, with reference to para. 23 of Council's Report, the Postmaster-General be requested to resume the telephone message service as soon as possible.

#### Surgical Corsets

Amendment by BELFAST: That, with reference to para. 31 of Council's Report, this meeting is of opinion that medical certification for surgical corsets should be completely abolished.

#### Allowances to Medical Witnesses in Civil Cases

Motion by HENDON: That, while noting the recommendations of the Departmental Committee on the up-grading of allowances payable to medical witnesses appearing in criminal cases (upon the adequacy of which comment is withheld temporarily), the Representative Body is firmly of opinion that any new scale of fees officially prepared for the guidance of Taxing Masters in assessing the sums payable to medical witnesses in civil cases should be fixed at a rate higher than that recommended as suitable for similar witnesses in criminal cases.

#### Fees payable to Examining Surgeons under the Factories Act

Amendment by WEST SUFFOLK: That the fees payable to certifying surgeons under the Factories Act are inadequate even with the present increase.

#### Examination of Candidates for Civil Service

Motion by BELFAST: That where in an examination of a candidate for the Civil Service the fee is paid by the patient, the patient should be entitled to a copy of the examiner's report.

### HOSPITALS

#### Shortage of Nurses

Motion by CITY: That this meeting is alarmed at the continued closure of wards and beds in hospitals and sanatoria through inadequate nursing and domestic staff. It calls on the Government to speed up all measures for attracting and retaining new entrants to the hospital service as a matter of extreme urgency, particularly by improved conditions of service and remuneration and simplification of the nursing curriculum.

Motion by BROMLEY: That this meeting is seriously worried by the shortage of nurses and domestic staff, which is interfering with the present hospital services, and which would prevent extension of these services; and proposes that the matter should be given urgent consideration by a special *ad hoc* committee with a view to making recommendations to the Council.

### MEDICAL ETHICS

#### Family Planning Association

Motion by HENDON: That the Representative Body is of the opinion that official recognition should not be accorded to the Family Planning Association by the appointment of B.M.A. representatives to their various committees.

### ORGANIZATION

#### Expenses of Members attending Meetings

Motion by MERIONETHSHIRE AND MONTGOMERYSHIRE: That legitimate out-of-pocket expenses be paid to representatives from central funds where such attendance at Representative Meetings necessitates staying a night or more away from home.

#### Grants to Divisions

Motion by WINCHESTER: That in the opinion of this meeting the grants received from Branch Councils for Divisional expenditure are inadequate, have been inadequate for a number of years, and are more so now in view of the increased cost of living. This meeting considers that grants should be increased to at least 10s. per head per annum.

### PUBLIC RELATIONS

Motion by DOVER AND FOLKESTONE: That in view of the adverse publicity being given to the medical profession in the lay press this meeting is dismayed at absence of counter propaganda from B.M.A. headquarters.

#### OTHER MOTIONS OF DIVISIONS

Motion by BROMLEY: That this meeting, having studied the proceedings of Council, congratulates them on so extensive a report, representing so much constructive work.

## GENERAL PRACTITIONER OBSTETRICIANS

A circular issued from the Ministry of Health to local authorities on July 10 reviews various services to be provided under the National Health Service Act. On the appointed day the maternity hospitals and homes now maintained by many welfare authorities will be transferred to the Minister; specialist services will be made available by the regional hospital boards and the services of a family doctor will be available to every expectant or nursing mother, as well as to every child. The Minister proposes that certain medical practitioners in each district shall be selected to practise midwifery; they will be called general practitioner obstetricians. The circular refers to these practitioners in the following words:

Subject to Regulations which have yet to be made, it is contemplated that every general practitioner will be given an opportunity to say whether or not he desires to practise midwifery under the general medical services of Part IV of the Act, and to answer calls by midwives for medical aid. The experience of the practitioners who desire to do so will be reviewed by a local *ad hoc* committee of a wholly professional character (consisting of local general practitioners, a consultant obstetrician, and the local health authority's medical officer of health) in each local health authority's area. This local committee will draw up a list of approved local practitioners and will be entitled to indicate to those who are not accepted for such a list the need for further obstetrical experience. The list would, of course, need to be reviewed from time to time with such objects as ensuring that the doctors on it are continuing to undertake enough midwifery to remain competent in practice, and adding the names of future entrants to the profession as they acquire the necessary experience. The duty of a family doctor, when consulted by a woman who is pregnant, will be to see that she knows how to obtain the services of a midwife and, if he himself is not on the local approved list, to help the woman to choose a "general practitioner obstetrician" from the approved list who will give her the necessary antenatal and post-natal care and will be present, if he thinks it necessary, or is called in by the midwife, at the confinement. An inclusive fee for general practitioner obstetricians, which will be additional to that payable for other general medical services under Part IV of the Act, will be centrally negotiated with the profession. The general practitioner obstetricians, together with the selected officers of the local health authority (see paragraph 14 (a) below), the midwives and a consultant obstetrician, will form composite obstetrical teams in each local health authority's area. In the course of time the general practitioner obstetricians will no doubt provide the bulk, if not the whole, of the medical staff for the local health authority's antenatal clinics, at which consultative clinics will also be held by the specialist obstetricians.

The Minister later points out in this circular that the Act empowers him to prescribe conditions as to the qualifications of the medical practitioners whose aid may be sought by midwives. Since he will use this power in relation to the general practitioner obstetricians, local authorities should not include any conditions about qualifications in their proposals.

## PETROL RATIONING PERIODS

The Ministry of Fuel and Power has decided to extend from four months to six months the rationing periods for supplementary allowances of petrol for private cars and certain other vehicles. For medical practitioners the next rationing period will cover the six months from Oct. 1, 1947, to March 31, 1948. This will be made clear in a printed letter which will accompany the issue of coupons in September. The change has been made for the convenience of business and professional car users and to secure staff savings in the regional petroleum offices. It does not mean that in future a four months' allowance will have to last for six months.

The Minister of Health is enlisting the aid of insurance committees in carrying out preparatory work on behalf of the executive councils which, under the N.H.S. Act, will organize the local family-doctor services. Insurance committees are co-operating by checking and bringing up to date their records of insured persons. The executive councils will need two registers—a nominal register of persons who have been accepted by doctors, and a medical register. The existing records of the insurance committees, reorganized in alphabetical order, will form the nucleus of the new registers.

## HEARD AT HEADQUARTERS

### A Word in Season

A ripple appeared on the surface of the Oxford Ophthalmological Congress when the smooth course of its scientific discussions was interrupted by a paper entitled "Making Perimetry Pay." The author was inclined to apologize for the use of the word "pay," and to interpret it as meaning rewarding in the scientific or clinical sense. His argument was that there was too great a tendency for field-taking in ophthalmology to be relegated to the junior or to the nurse or perhaps to the hospital porter, and that it was worth while for the senior man in the clinic to get off his perch and take the field himself. But one subsequent speaker insisted on the commercial aspect. He was delighted that Oxford should have allowed the word "pay" to come into prominence. "It shows we are coming on. We have got to make ophthalmology pay if we are to provide a good service."

### Motions at the A.R.M.

The agenda of the Annual Representative Meeting contains 159 motions and amendments. Nevertheless, it is hoped not to prolong the meeting beyond two days and a half. One feature which will strike those accustomed to the proceedings of the A.R.M. is that there is only one motion which does not relate to the Annual Report of Council. Generally there have been a score or so of such "Other motions from Divisions and Branches," which have often occupied a whole morning. The single motion on this occasion is one from Bromley congratulating the Council on its extensive report, representing so much constructive work. It has been decided to recommend that there is to be no curtailment of speeches beyond the time limits laid down in standing orders—15 minutes for the mover of a resolution, 10 minutes for an amendment, and 5 minutes for other speakers—a generous allowance in comparison with what obtains in other assemblies. But this time the duration of the speeches is to be recorded and will be reviewed in time for the next Annual Representative Meeting. Of course, it will still be possible for a representative to move at a later stage that in view of the state of business the time allowed to speakers be curtailed for the rest of the session.

### The Prescient Minister

Mr. Bevan, speaking at the Tuberculosis Conference, seemed to hint that an amending Act was likely. After making his speech to the delegates he listened to criticisms from Wales and Scotland concerning arrangements for the tuberculosis service under the new Act, and then in a few words before he left for the House of Commons he said that a good deal of the misunderstanding which had been voiced was due to the fact that the present Act was simply a sketch, and that, for anything his critics knew, their objections had been anticipated already. "You may not have thought that the Minister of Health was so prescient," he said, and he added *sotto voce* something about new legislation which was not properly caught even at the Press table just below him.

### The First Executive Council

What Lancashire thinks to-day . . . The first Executive Council to be formed in the country under the National Health Service Act, according to the mayor of Oldham, has been set up in that town, and in a manner which promises well. No difficulty was experienced in securing the professional side of the Council. The meeting to transform the old Insurance Committee into the Executive Council was held on June 13, when it was announced that the chairman of the Insurance Committee had been chosen by the Minister as chairman of the new body, a choice acceptable to all concerned. For the vice-chairmanship a doctor was elected—Dr. R. I. Poston, honorary secretary of the Oldham Medical and Panel Committee. A local alderman was also nominated for the position, but Dr. Poston was elected by a majority of about two to one. It will be remembered that according to the Act the Executive Council which each local health authority is required to set up must consist, in addition to the chairman, of 24 members, of whom seven are appointed by the Local Medical Committee.

It is gratifying to find in this cotton city the amicable tradition of the Insurance Committee continued, and also a doctor in the vice-chair.

### The Voluntary Principle

Sir Wilson Jameson, Chief Medical Officer to the Ministry of Health, must have blushed when, occupying the chair at the International Conference on Maternity and Child Welfare, he heard himself described by a lady speaker as "the architect of the new Health Service whose wand will awaken the Sleeping Beauty and whose rod will ward off Caliban." Evidently the tools of an architect are more varied than we had thought. But when another lady councillor said, rather complacently, that the change-over from voluntary to State organization meant the replacement of the untrained worker by the trained, Sir Wilson Jameson spoke very emphatically (as his Minister had done earlier in the conference) on the value of voluntary organizations. He declared that voluntary organizations had to be given as prominent a place in the future as in the past, and it would be a sad day when voluntary work came to an end. Both voluntary and official organizations employ trained people to do technical work, and there is no question of any change in this respect. But the voluntary organization can do something which the official organization cannot do—it can take a chance.

### Government Hearing Aids

From letters received at Headquarters there seems to be a good deal of questioning about the scheme for distribution of hearing aids. It should be said at once that no approval of any scheme has been given by the British Medical Association. About two years ago a special committee was set up to advise the Medical Research Council on research into problems relating to the design and production of instruments for the alleviation of deafness. The purpose in view was to devise an instrument that could be produced at reasonable cost, and the Minister of Health has given an undertaking that arrangements will be made for facilities for the proper diagnosis of cases and the adjustment of the apparatus to the individual case. Obviously the important thing in this venture is not the mass production of 50,000 instruments but the individual adjustment and, moreover, instruction in use and maintenance.

## H.M. Forces Appointments

### ROYAL NAVY

Temporary Surgeon Lieutenants (R.N.V.R.) T. C. Barras, P. V. G. Dawson, and B. Marsden have been transferred to the Royal Navy.

### ARMY

Major-General W. C. Hargitt, C.B., O.B.E., M.C., K.H.S., late R.A.M.C., having completed four years in the rank, is retained on the Active List supernumerary.

Colonel (Temporary Major-General) W. E. Tyndall, C.B., C.B.E., M.C., late R.A.M.C., to be Major-General.

Colonels F. Harris, C.B.E., M.C., and J. J. Magner, M.C., late R.A.M.C., have been granted the acting rank of Major-General.

Colonel H. B. F. Dixon, M.C., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Brigadier.

Colonels K. P. Mackenzie, R. H. Alexander, M.C., and W. Campbell, late R.A.M.C., have retired on retired pay.

Colonel C. Scales, M.C., late R.A.M.C., having attained the age for retirement, is retained on the Active List supernumerary.

Lieutenant-Colonel (Local Brigadier) J. Bennet, from R.A.M.C., to be Colonel.

Lieutenant-Colonels R. H. C. Pryn and B. J. Daunt, O.B.E., from R.A.M.C., to be Colonels.

Major J. B. Hanafin, C.I.E., I.M.S., retired pay, has been restored to the rank of Lieutenant-Colonel on ceasing to be re-employed.

### ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonels D. F. Panton, C.B.E., and D. W. M. MacKenzie, having attained the age for retirement, are retained on the Active List supernumerary.

Lieutenant-Colonel W. H. Cornelius has reverted to retired pay on ceasing to be employed.

Lieutenant-Colonel T. F. M. Woods, O.B.E., has been seconded under the Ministry of Food. (Substituted for the notification in a *Supplement to the London Gazette* dated Feb. 25.)

Majors (War Substantive Lieutenant-Colonels) R. Johnston, J. C. Barnesen, O.B.E., J. B. Macfarlane, H. J. R. Thorne, D.S.O., and B. Blewitt to be Lieutenant-Colonels.

War Substantive Major G. L. Ritchie has been seconded under the Ministry of Food.

War Substantive Major R. G. Boyd, M.C., has retired on account of disability and has been granted the honorary rank of Lieutenant-Colonel.

LONDON SATURDAY JULY 26 1947

## MEDICINE IN THE POST-WAR WORLD\*

BY

Sir HUGH LETT, Bt., K.C.V.O., C.B.E., F.R.C.S.

It is not usual for the President to review the work of the Association when he gives his Address at the Annual Meeting, but so much has happened during the last twelve months that it is perhaps well to recall some of the principal events, if only to remind ourselves—and others—of the immense amount of work that is done by the Association and the wide field it covers.

### The B.M.A. and National Health Service

The National Health Service Act has, of course, overshadowed everything else. Its far-reaching clauses have called for the most careful scrutiny and the Act has placed a heavy responsibility on the Council, for the Association now has over 55,000 members, including 75% of those actively engaged in practice in Great Britain and Northern Ireland. I need not say how essential it is that every member of the profession should be fully informed of all that the Act implies, that he should study its various clauses in the light of his special knowledge as a medical practitioner and consider how they will ultimately affect the care of the sick and the interests of the patients and how they will influence medical practice.

In some quarters there are misunderstanding and misrepresentation of the attitude of the B.M.A. and the medical profession. It is said that from a narrow self-centred interest the Association is opposing the Act as a whole, and, indeed, that it is prepared to obstruct any attempt to improve the medical services of the country. In actual fact the Association has been responsible for much progress in many directions to the great advantage of the health of the people, and for the last twenty-five years it has repeatedly urged that there should be a reorganization of the medical services. In 1941, with the co-operation of the Royal Colleges, the Scottish Corporations, and other bodies, it set up the Medical Planning Commission to consider and make recommendations for a national health service. In due course the Commission published an interim report, and this had its influence on the development of the present Act. But there are clauses in the Act which many doctors feel that they cannot accept, for while they are looking forward to a co-ordinated national health service, which is so much needed, they are most anxious that it shall be one that will give the greatest possible help to the community, one that will preserve the best traditions of the profession in their treatment of the sick, and one that will allow doctors to work under conditions which will enable them to give of their best. Above all, nothing must be allowed to interfere with the trust of the patient in his doctor and the belief that he is his doctor's first con-

sideration, for this trust and belief mean much to the patient and play an important part in successful treatment.

### Co-operation within the Profession

Unity within the profession is perhaps our greatest need to-day and we have been trying to meet this need by strengthening our organization. We are fortunate in our admirable secretariat led by Dr. Charles Hill, and the new arrangement is working well by which the Assistant Secretaries make periodic visits to different parts of the country, helping to keep the profession in touch with what is going on in London at the centre, and—equally important—conveying back to Headquarters the views, criticisms, and suggestions from our members in the Divisions.

Anything that makes for wider co-operation and unity is important, because it is only on the basis of such unity that we can move on to fruitful work in other fields. The Association has been exploring means whereby medicine throughout the Commonwealth and Empire can be advanced and can play its part in strengthening those bonds which mean so much to us all and which in years to come may prove a pattern to the whole world. We have long been anxious that our relations with our colleagues overseas should be developed and become still closer, and we know that this feeling is shared by them. To this end we believe that greater opportunities should be provided for personal contact so that views can be exchanged and difficulties discussed by word of mouth. In no other way can we have a complete understanding of each other's problems, nor can anything do more to strengthen our relations than the development of personal friendships. The Council has therefore decided to recommend that the affiliated and daughter Associations in the Commonwealths should be invited to co-operate in establishing a British Commonwealth Medical Council. Each would appoint its own direct representatives, and it is suggested that the meetings should be held in the principal centres overseas as well as in London.

The objects of this Council would be:

To develop and maintain closer contact between practitioners in the United Kingdom and in the Dominions and between medical practitioners in the various Dominions.

To advance the status of British medicine.

To stimulate discussions and exchange of advice on matters of common interest.

To promote an interchange of professional facilities.

It is also proposed to establish an Empire Medical Advisory Bureau at B.M.A. House for giving advice and help to those who come here from the Commonwealths and the Colonies for postgraduate or under-

\* The Presidential Address delivered to the Annual General Meeting of the Association on July 23.

*Short Service Commissions, Specialists.*—War Substantive Major R. P. Boyd, from Emergency Commission, to be Captain; War Substantive Captain B. Bevan, from Emergency Commission, to be Captain.

*Short Service Commissions.*—War Substantive Captains F. J. B. Douglas and A. H. L. Wilson, from Emergency Commissions, to be Captains. Lieutenants R. W. Campbell and J. Prentice, from Emergency Commissions, to be Lieutenants. The notification regarding R. Saffley in a *Supplement to the London Gazette* dated May 13 is cancelled.

## LAND FORCES: EMERGENCY COMMISSIONS

### ROYAL ARMY MEDICAL CORPS

War Substantive Captains R. P. Baird and A. D. Cuthbert have relinquished their commissions and have been granted the honorary rank of Captain.

War Substantive Captains L. G. Kiloh, R. B. Coles, R. J. Jameson, and M. J. Morton have relinquished their commissions on account of disability and have been granted the honorary rank of Captain.

Lieutenant C. L. Dubberley has relinquished his commission on account of disability and has been granted the honorary rank of Lieutenant.

*Short Service Commission, Specialist.*—Lieutenant R. Saffley to be Lieutenant.

To be Lieutenants: F. G. Badger, H. L. Binnie, W. Brodie, J. Carswell, D. A. Chadwick, I. W. Clark, B. S. Cooper, P. W. Darby, A. Deuchars, T. Dungavel, R. M. Duncan, M. P. Durham, G. H. Field, K. D. Foggitt, R. B. Forbes, W. Garrett, A. Goldberg, E. G. Green, A. W. I. Hall, T. Hart, M. M. Herbert, P. Holliday, J. J. Hopkinson, A. W. J. Houghton, R. Houston, J. M. Hughes, K. Hugh-Jones, R. McG. Inglis, G. Jarratt, D. H. Johnson, P. D. Kelsall, S. S. Lawton, J. D. L. Jones, A. McClelland, E. Macdonagh, F. McKerracher, J. Maclean, J. K. McMyn, J. R. Milne, F. R. D. Minett, R. R. W. Mirrey, F. S. Mooney, N. A. Oppenheim, O. E. Owen, M. D. M. Reilly, D. A. Richmond, H. A. Scott, J. S. Scott, J. A. Stoll, J. S. Swallow, A. H. Swithinbank, M. Symons, W. D. G. Tellam, C. G. Teverson, J. H. M. Thomas, H. J. Voss, R. W. E. Watts, T. Wilson, B. A. Woodger, K. D. Woolas, J. T. Wright, D. Yuille, D. M. C. Ainscow, W. G. L. Allan, J. G. Bearn, G. H. F. Beith, W. L. Blackett, W. J. O. Box, D. K. Briggs, J. A. W. Brown, D. M. Caird, H. MacD. Cameron, M. G. Cox, D. M. Davies, W. H. Davies, D. J. Dennison, D. Dexter, A. W. Downie, H. Droller, D. Duncan, J. C. Duggan, M. R. Fell, H. Fishbone, A. D. B. Fotheringham, K. H. Fraser, J. B. Frost, A. Gillis, C. E. T. Gordon, D. Hamilton, J. Harding-Cox, C. A. Haxton, R. B. Hendry, R. W. L. Hurt, J. S. Inkster, C. M. Jockel, K. S. Jones, W. de M. Kellock, J. W. Laws, E. T. Lay, J. Leary, R. E. D. Leigh, W. D. Linsell, D. M. O. Lowry, P. M. F. McGarry, W. J. M. Mackenzie, I. K. R. McMillan, R. H. McVean, T. C. H. Matthews, J. J. Medalia, P. H. Merlin, G. D. N. Milne, R. G. Milne, W. Oldham, R. E. O'Neal, J. R. Page, T. J. S. Patterson, B. W. Perlow, R. W. Povey, J. Price, M. Redfern, N. C. Rees, J. W. A. Rodgers, G. E. Stein, C. C. D. Shute, C. E. D. Taylor, A. K. Thomas, R. H. Thomlinson, W. P. Thomson, and C. D. Davoine.

### ROYAL AIR FORCE

Air Commodore K. Biggs, C.B.E., M.C., has retired and is re-employed.

Group Captain P. A. Hall has retired and is re-employed. Wing Commander C. R. Palfreyman has retired at his own request, retaining the rank of Group Captain.

Squadron-Leader (Temporary Wing Commander) H. L. Willcox to be Wing Commander.

To be Squadron-Leaders: E. A. Rice, C. G. Burgess, E. H. Lamb, R. Maycock, S. Paul, F. V. MacLaine, R. C. O'Grady, J. H. Lewis.

To be Flight-Lieutenants: D. Crichton, M.B.E., W. G. Alexander, J. M. Ferguson, D. Stevenson, M.B.E., W. L. Price, E. C. B. Bramwell, J. M. Urquhart, J. K. F. Mason, H. C. Thomas, W. C. Baird, P. S. Krusin, W. O. Davies, T. N. N. Brennan, and S. E. Cupples.

J. N. C. Cooke to be Flying Officer.

### AUXILIARY AIR FORCE

To be Flight-Lieutenants: F. R. C. Manning, W. D. Coltart, J. H. Pool, A. Skene, M.B.E., T. F. Stewart, J. L. Coleman.

### ROYAL AIR FORCE VOLUNTEER RESERVE

To be Squadron-Leaders: M. Lentin, D. A. J. Ebrill, A. H. Galley, H. Kopelman, W. C. Lawrence, E. J. Radley-Smith, L. E. Jones, J. S. Lawrence, D. C. Devitt, J. E. G. Pearson, J. S. F. Sutton, W. C. Good, O. Janus, J. Rubin, R. H. Dale, R. A. Fleming, E. G. Hall, W. Tennent, B. J. Sanger, J. L. Reid, D. A. Sanford. Flight-Lieutenants (honorary) J. G. Lynch, R. J. Sims, and J. Tolson-Smith have relinquished their commissions on cessation of duty.

Flight-Lieutenants A. Skene, T. F. Stewart, and J. L. Coleman have relinquished their commissions on appointment to the reconstituted A.A.F., retaining the rank of Squadron-Leader.

Flight-Lieutenants D. G. Ismay and O. L. S. Scott have resigned their commissions retaining the rank of Squadron-Leader.

Flight-Lieutenant W. F. Buchanan has resigned his commission, retaining his rank.

Flight-Lieutenant F. R. C. Manning has relinquished his commission on appointment to the reconstituted A.A.F., retaining his rank.

Flight-Lieutenant G. Wilkinson has relinquished his commission on account of medical unfitness for Air Force service.

To be Flight-Lieutenants (Emergency): G. H. Bancroft-Livingstone and A. J. K. Gallagher.

Flying Officers T. W. G. Donohoe, T. D. Duke, I. S. Ferguson, D. F. Gibbs, L. Griffiths, J. Lawson, R. S. MacLachlan, I. D. W. Skempton, N. C. T. Watford, G. I. Clarke, R. W. Drew, B. R. Hillis, R. F. Jackson, I. H. Pratt, W. T. D. Ray, J. H. Robinson, M. G. Scott, A. A. Cohen, M. Evans, I. H. Foy, W. Hamilton, J. T. Hutchinson, D. Leigh, D. MacLeod, A. R. Makey, J. Rubin, P. H. Thomas, P. West, T. A. Evershed, J. J. Fleming, D. P. Greaves, B. A. J. C. Gregory, D. G. Jones, W. K. Jones, N. B. Malleon, S. H. Manners, J. H. Murphy, P. R. Ormrod, I. A. Porter, T. M. Roulston, W. M. Sandeman, G. H. Seale, D. W. S. Shelddon, D. L. Davies, R. T. D. Emond, P. Foster, J. Freedman, R. Just, G. M. McGillivray, I. H. Mercer, I. S. Mudie, L. Shuck, E. Silver, R. D. Simpson, C. J. W. Soutar, R. H. Stillman, J. B. Stirling, H. F. Sugden, H. D. Symon, J. M. Thomas, D. K. M. Toye, J. D. Willins, R. R. Wilson, J. R. Anderson, M. M. Andrew, G. M. Burns, A. Campbell, W. J. Jenkins, W. J. W. Sharrard, J. D. Abbott, E. M. Allen, J. A. Cameron, J. A. Chalmers, J. D. Chalmers, R. S. Crow, L. D. Davidson, P. S. Dearden, H. Debovitch, J. Edwards, T. Ellis, D. Emslie-Smith, D. I. Ferguson, A. G. C. Findlater, J. K. Fleming, J. A. Gavin, C. Gething, H. S. Heddl, W. N. Kingsbury, J. R. McPherson, J. B. Masefield, P. F. New, J. C. Reid, J. B. Russell, D. A. Sherman, T. J. Thomson, W. S. T. Thomson, N. D. Ashe, G. F. Bacon, G. L. Bickler, N. F. W. Brueton, J. G. Coxon, W. J. A. Dobson, L. G. Duff, J. Fraser, W. E. Hassan, J. F. Hudson, P. K. S. Joynton, C. H. Kinder, W. R. Lee, K. E. Melver, I. Mackenzie, R. W. P. Mellish, D. O'Keefe, A. S. Oxier, I. M. Perkins, A. P. Roberts, P. Seltzer, J. G. Shirreffs, H. Shooman, D. F. Street, W. C. Taylor, C. C. Vidot, R. V. Walley, L. P. Whittaker, R. A. Wilkinson, D. G. Wilson, D. Wimborne, J. Bart, J. S. Caldwell, K. D. Cochran, N. N. Davies, E. F. Ducat, R. F. Ewing, K. J. R. Ford, J. D. Galletly, G. E. Griffiths, F. Latham, P. S. London, R. C. McGregor, C. B. McKerrrow, J. McMillan, P. R. Montgomery, G. W. Morrison, J. A. B. Mounsey, W. D. Nicoll, A. C. F. Ogilvie, J. O. Robinson, P. F. Scott, P. H. S. Silver, D. L. C. Thomas, M. Tobias, J. C. L. Wade, R. W. Wilkinson, C. D. Wilson-Sharpe, and C. E. Phillip to be War Substantive Flight-Lieutenants.

Flying Officer M. A. Coleman has relinquished his commission on account of medical unfitness for Air Force service.

To be Flying Officers (Emergency): R. R. Davis, A. J. Fouracre, N. L. Gilburn, J. Hegarty, M. S. Hughes, G. A. S. Lloyd, W. Lyons, E. P. Mackenzie, J. Alterman, I. C. Geddes, G. C. Hunter, D. M. Leahy, E. C. Levine, P. M. Lynch, A. McDermott, P. N. Magee, J. S. Marshall, M. D. Warren, N. P. Watson, C. E. Williams, and R. W. Watson.

## WOMEN'S FORCES

### EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

B. D. Wright to be War Substantive Flight-Lieutenant. Anne M. O'Riordan to be Flying Officer (Emergency).

### ARMY IN BURMA RESERVE OF OFFICERS

#### EMERGENCY COMMISSION

V. Natarajan to be Lieutenant.

### COLONIAL MEDICAL SERVICE

The following appointments have been announced: G. C. Cochrane, M.R.C.S., L.R.C.P., Medical Officer, Kenya; M. G. Corcos, M.R.C.S., L.R.C.P., Medical Officer, Leprosy Control Service, Nigeria; J. O. Creighton, M.R.C.S., L.R.C.P., Medical Officer, Nyasaland; D. C. Davidson, M.R.C.S., L.R.C.P., Medical Officer, Northern Rhodesia; D. J. B. Falconer, F.R.C.S., Lady Medical Officer, Nigeria; I. P. Mackenzie, M.B., Ch.B., D.P.H., Woman Medical Officer, Tanganyika Territory; B. M. Mcowan, M.B., B.S., Medical Officer, Malaya; E. M. Sawdon, M.B., Ch.B., Lady Medical Officer, Malaya; R. H. O. Bannerman, M.B., B.S., Medical Officer (African), Gold Coast; K. Brown, M.B., Lady Medical Officer, Northern Rhodesia; Z. Galis, M.D., District Medical Officer, Grenada, Windward Islands; F. A. E. Hamilton, M.R.C.S., L.R.C.P., Medical Officer, Grade "C," Trinidad; L. D. Healy, M.B., B.Ch., Medical Officer, Sierra Leone; J. Ross-Innes, M.D., Leprosy Specialist, East Africa; A. Relwicz, M.D., Medical Officer, British Guiana; J. M. K. Robertson, L.R.C.P.&S., Medical Officer, Gold Coast; N. C. Macleod, M.B., Ch.B., D.P.H., Deputy Director of Medical Services, Gold Coast.

## MEDICINE IN THE POST-WAR WORLD\*

BY

Sir HUGH LETT, Bt., K.C.V.O., C.B.E., F.R.C.S.

It is not usual for the President to review the work of the Association when he gives his Address at the Annual Meeting, but so much has happened during the last twelve months that it is perhaps well to recall some of the principal events, if only to remind ourselves—and others—of the immense amount of work that is done by the Association and the wide field it covers.

### The B.M.A. and National Health Service

The National Health Service Act has, of course, overshadowed everything else. Its far-reaching clauses have called for the most careful scrutiny and the Act has placed a heavy responsibility on the Council, for the Association now has over 55,000 members, including 75% of those actively engaged in practice in Great Britain and Northern Ireland. I need not say how essential it is that every member of the profession should be fully informed of all that the Act implies, that he should study its various clauses in the light of his special knowledge as a medical practitioner and consider how they will ultimately affect the care of the sick and the interests of the patients and how they will influence medical practice.

In some quarters there are misunderstanding and misrepresentation of the attitude of the B.M.A. and the medical profession. It is said that from a narrow self-centred interest the Association is opposing the Act as a whole, and, indeed, that it is prepared to obstruct any attempt to improve the medical services of the country. In actual fact the Association has been responsible for much progress in many directions to the great advantage of the health of the people, and for the last twenty-five years it has repeatedly urged that there should be a reorganization of the medical services. In 1941, with the co-operation of the Royal Colleges, the Scottish Corporations, and other bodies, it set up the Medical Planning Commission to consider and make recommendations for a national health service. In due course the Commission published an interim report, and this had its influence on the development of the present Act. But there are clauses in the Act which many doctors feel that they cannot accept, for while they are looking forward to a co-ordinated national health service, which is so much needed, they are most anxious that it shall be one that will give the greatest possible help to the community, one that will preserve the best traditions of the profession in their treatment of the sick, and one that will allow doctors to work under conditions which will enable them to give of their best. Above all, nothing must be allowed to interfere with the trust of the patient in his doctor and the belief that he is his doctor's first con-

sideration, for this trust and belief mean much to the patient and play an important part in successful treatment.

### Co-operation within the Profession

Unity within the profession is perhaps our greatest need to-day and we have been trying to meet this need by strengthening our organization. We are fortunate in our admirable secretariat led by Dr. Charles Hill, and the new arrangement is working well by which the Assistant Secretaries make periodic visits to different parts of the country, helping to keep the profession in touch with what is going on in London at the centre, and—equally important—conveying back to Headquarters the views, criticisms, and suggestions from our members in the Divisions.

Anything that makes for wider co-operation and unity is important, because it is only on the basis of such unity that we can move on to fruitful work in other fields. The Association has been exploring means whereby medicine throughout the Commonwealth and Empire can be advanced and can play its part in strengthening those bonds which mean so much to us all and which in years to come may prove a pattern to the whole world. We have long been anxious that our relations with our colleagues overseas should be developed and become still closer, and we know that this feeling is shared by them. To this end we believe that greater opportunities should be provided for personal contact so that views can be exchanged and difficulties discussed by word of mouth. In no other way can we have a complete understanding of each other's problems, nor can anything do more to strengthen our relations than the development of personal friendships. The Council has therefore decided to recommend that the affiliated and daughter Associations in the Commonwealths should be invited to co-operate in establishing a British Commonwealth Medical Council. Each would appoint its own direct representatives, and it is suggested that the meetings should be held in the principal centres overseas as well as in London.

The objects of this Council would be:

To develop and maintain closer contact between practitioners in the United Kingdom and in the Dominions and between medical practitioners in the various Dominions.

To advance the status of British medicine.

To stimulate discussions and exchange of advice on matters of common interest.

To promote an interchange of professional facilities.

It is also proposed to establish an Empire Medical Advisory Bureau at B.M.A. House for giving advice and help to those who come here from the Commonwealths and the Colonies for postgraduate or under-

\* The Presidential Address delivered to the Annual General Meeting of the Association on July 23.

graduate study, and I am glad to say that in this work we are already assured of the sympathetic co-operation of London House. The work of the Bureau will not be limited to giving advice on academic matters; it is hoped that it will also help socially in various ways, as, for example, by assisting men to find accommodation and putting them in touch with their British colleagues. Some of those who come to this great metropolis feel lost, rather bewildered, and not a little lonely, and one of the main objects in setting up this Bureau is to provide a centre where all who come from overseas to study medicine in this country will receive a warm welcome and be made to feel that they are at home and not visitors in a strange land.

### The World Medical Association

I have pursued this theme of professional co-operation, and of unity in co-operation, from our domestic matters at home to the wider field of work in our relations with the Commonwealth. There is still one further stage, and here too an advance has been made in the last year. I refer to the world-wide interests of medicine. Last September an International Medical Conference was held in London on the initiation of the British Medical Association, and as a result there was formed the World Medical Association, which will be holding its first annual meeting in Paris in September. It is expected that the delegates of at least thirty countries will be present at this inaugural conference. The objects set out in the provisional Articles and By-Laws of the W.M.A. are as follows:

(1) To provide closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available in order to assist all peoples of the world to attain the highest possible level of health.

(2) To study the professional problems which confront the medical profession in the different countries.

(3) To organize an exchange of information on matters of interest to the medical profession.

(4) To establish relations with, and to present the view of the medical profession to, the World Health Organization, other appropriate bodies.

It is thought that the formation of the World Medical Association is unnecessary and redundant in view of the existence of the World Health Organization, but the difference between these two bodies in composition and function should be clear. The World Health Organization is the organization of the Governments of the world; the World Medical Association will represent the medical associations of the world. In to-day's jargon the one will function as the Government "level," the other at the professional level. The W.H.O. cannot be fully effective unless it has the support of the medical profession, and concerted action on which will enable the profession to present its views to the W.H.O. is surely desirable. I would only add that the organizing committee of the W.M.A. has received cordial messages of approval and encouragement both from W.H.O. and from Unesco.

The W.M.A. has already taken steps in the pursuit of its second object, and has set on foot an inquiry into the trend of State policy in relation to medicine in different countries. The underlying question of this fact-finding inquiry is whether and to what extent State intervention in medical services has involved radical changes in professional conditions and methods of medical practice. We may hope that the W.M.A. by its ability to put forward to the different political authorities the experience of those actually engaged in the practice of medicine in so many countries will be able to exert a valuable influence on national medical policies.

### Association Activities

You will all have had the Annual Report of the Council, so I need not do more than refer very briefly to the many other activities of the Association. Valuable scientific reports making far-reaching recommendations have been published by the Association during the year—those, for example, on the care and treatment of the elderly and infirm, and on various problems touching psychiatry and the law. Again, the constantly developing field of medical education has not been neglected, as witness the work on films and on the curriculum. All these developments demonstrate the Association's interest in all that touches the advance of medicine. I would also refer to a committee that was recently appointed to make a full investigation into the form or forms health centres might take. Extensive inquiries are being made from doctors engaged in group practices, smaller partnerships, and single-handed practices in town and country, with a view to finding out the advantages and disadvantages and difficulties of each type. A large mass of information will be collected and the report should be very valuable. We hope that both it and the *Memorandum on the Care and Treatment of the Elderly and Infirm* will be of assistance to the Minister, the regional bodies, and local authorities, and prove useful guides in what must be important parts of the new Health Service.

A special word of praise is due to the Journal Committee and the Editor of the *British Medical Journal*; for, although the difficulties in connexion with paper and printing during the last year have been greater than at any time since 1939, they have not only maintained the high standard of the *B.M.J.* and provided for its steadily increasing circulation, but they have been able to embark on new ventures. The most important was the publication of the first numbers of *World Abstracts*—one volume devoted to medicine and another to surgery, obstetrics, and gynaecology. They cover the world literature and are a great undertaking. It is clear from the early numbers that they will prove of the utmost value to medical men throughout the world.

For many years the Association has undertaken the publication of quarterly journals on special branches of medicine and surgery, and during the last twelve months it has arranged to publish two more, thus bringing the total number to ten. It is to be congratulated on the important contributions it is making to medical literature and to the progress of medical science.

### Conclusion

In this brief sketch I have touched on only a few of the activities of the Association, but they are enough to show how wide its interests are and to give some indication of its value both to the country and to the profession.

The British Medical Association holds a unique position, for it represents the great majority of the practitioners in every branch of medicine, and in particular those who are engaged in general practice. In its constitution it is essentially democratic, and each practitioner through its Branches and Divisions, or by direct communication to the Council, can draw attention to his difficulties. The Council is the executive body, helped by numerous committees, but all questions of policy are decided by the Representative Body at its Annual Meeting of representatives of Branches and Divisions.

The steady increase in membership is very satisfactory and encouraging, but, great as our numbers are now, we hope they will be even larger; for we are at the beginning of an age that is bringing many changes, and the future is obscure. In the past many doctors have devoted them-

selves entirely to their practice and have given little thought to the organization of the profession. But the time has come when this isolation and inertia must give place to an active interest. The attempt by some local authorities to compel their medical officers (and nurses) to belong to a particular body, whether a trade union or not, is a threat to our freedom as individuals, and in it we see a warning of what is to come. We stand for professional and individual freedom: our membership is voluntary—we are proud of it, and intend that it shall remain so.

We are living in days when the individual is coming to count for little, and there is a danger that excessive concentration of power in the hands of the State may in time tend to reduce all voluntary associations to an ancillary if not a decorative function. Yet in most great nations, certainly in all the Anglo-Saxon communities, innumerable voluntary associations—professional, cultural, economic, spiritual—have been the pioneers of all humanitarian development, the “cutting edge” as it were of Progress. It is true that the present Government is anxious for voluntary effort to continue; but Ministers and officials come and go, and we must take thought for the future. For this reason we must be vigilant and do all that is possible to secure and maintain the unity of our profession. Vigilance alone is not enough—in union will lie our strength.

The difficulties that confront us are many and considerable, but with wise resolution and statesmanship the Association will emerge with even greater authority, and, in the forefront of all that concerns the national health, it will continue its pursuit of the aims laid down in its Memorandum of Association nearly three-quarters of a century ago: “To promote the medical and allied sciences and to maintain the honour and interests of the profession.”

## SURGICAL ASPECTS OF AMOEBIASIS

BY

P. THERON, F.R.C.S.Ed.

*From the Department of Surgery, University of Aberdeen*

During the recent war amoebic colitis was so prevalent that it constituted a major problem for the medical services. Of greater importance, however, was the disturbingly high relapse rate after treatment: Payne (1945) estimated that in India alone a 20% carrier rate existed among British troops. It seems likely, therefore, that the complications of amoebic dysentery will play an important part in post-war civilian practice. In the surgical sphere an infection of this type is apt to give rise to considerable difficulty in diagnosis, and may at the same time exert a great influence on the course and outcome of surgical ailments and, in particular, on the results of operative treatment. A discussion of some aspects of amoebiasis, based mainly on experience gained in the surgical wards of the King Edward VII Hospital, Durban, may therefore be of interest.

### General Influence on Operative Treatment

The mortality rate following operations on patients suffering from untreated and often undiagnosed amoebic infection is considerable. This is largely explained by: (a) The reduced resistance as a result of the chronic infection, with consequent increase in the number and severity of post-operative complications. A factor of importance is the frequent association of hypoproteinaemia with amoebic infection (Faust, 1930; Elsdon-Dew, 1946). The predisposition towards the development of post-operative complications

caused by this type of deficiency is too well known to require amplification. (b) The interference with wound-healing, with the occurrence in some cases of ulceration and sloughing of the skin of the abdominal wall. This complication is especially apt to occur after the establishment of a colostomy. (c) The tendency to “breakdown” at the suture line after operative intervention on the bowel. Consequently, procedures such as intestinal anastomosis, appendicectomy, etc., may be associated with the development of faecal fistulae and general peritonitis. (d) The development of acute amoebic dysentery during the immediate post-operative period—probably the result of handling of the bowel during operation. In most cases this is of little moment, provided that early treatment is instituted. On occasion, however, the condition may simulate bacillary dysentery in the severity of the diarrhoea, with a consequent adverse effect on the prognosis. It is of interest that this phase of acute diarrhoea may occur within forty-eight hours of operation on patients suffering from severe general peritonitis. This was a feature in two cases in which the development of paralytic ileus had appeared almost inevitable; stool examination revealed the presence of numerous free forms of *Entamoeba histolytica* with ingested erythrocytes. (e) During the post-operative period a mild hepatitis is not uncommon. Spontaneous remission is usual, but occasionally a progressive form is encountered. The following case report is illustrative.

A Zulu male aged 58 was admitted to hospital shortly after being stabbed in the left lumbar region. Laparotomy revealed partial severance of the renal pedicle, with laceration of the tail of the pancreas. Nephrectomy was followed by repair of the pancreatic lesion, with drainage of the site. The development of a pancreatic fistula caused a stormy convalescence, but by the twenty-first day the wounds had healed and the patient was allowed up. Four days later sudden relapse occurred, and rapid deterioration culminated in death. Post-mortem examination revealed the presence of a typical amoebic abscess, partly protruding from the lower surface of the liver and surrounded by numerous smaller areas of necrosis and liquefaction. It seems probable that the combination of operative trauma and the general reduction in resistance precipitated a rapidly progressive type of hepatitis.

Many of these post-operative complications are likely to occur in Britain during the post-war years. Failure to recognize the cause may be disastrous. Thus it would be good policy to view with suspicion every candidate for operation who has seen service in a tropical or subtropical zone, whether or not a history of dysentery is elicited; and, where possible, pre-operative investigation in the form of sigmoidoscopy and stool examination should be employed. After emergency operations a watchful eye should be kept for complications suggestive of amoebiasis, so that early and energetic treatment may be instituted if necessary.

### Abdominal Amoebiasis

#### Acute Hepatitis and Hepatic Abscess

In the classical case of acute hepatitis, in which the maximum intensity of pain is present in the lower costal, subcostal, or epigastric areas, the diagnosis is seldom difficult. However, the atypical form, simulating acute cholecystitis, perforation of peptic ulcer, acute appendicitis, or even renal colic may act as a surgical stumbling-block. During the early stages of a severe infection of this type pain, tenderness, and resistance may be so generalized as to suggest the onset of general peritonitis, while not infrequently the signs may be maximal in the right iliac fossa. Occasionally the presence of a “reflex ileus” in association with persistent vomiting, constipation, and distension provides a picture difficult to distinguish from that of acute intestinal obstruction. The immediate problem,

therefore, is the elimination of acute abdominal conditions requiring urgent operative treatment.

Although a history of amoebic dysentery may be lacking, the patient should be carefully questioned regarding overseas travel. Any previous contact with a tropical or sub-tropical zone should be viewed with suspicion in relation to possible exposure to infection. It is characteristic of this condition that the clinical picture may change completely over a period of one or two hours. It is advisable, therefore, to repeat the examination at frequent intervals until such time as the diagnosis is established. Antero-posterior compression of the thorax, gentle "fist" percussion over the lower ribs, and auscultation of the right pulmonary base are measures which may be of value when locating the site of the lesion. Constipation, rather than diarrhoea, is the common finding. Consequently, during the initial phase, when the diagnostic difficulties are most pronounced, adequate stool examination is rarely possible. Sigmoidoscopy, however, should be performed in all doubtful cases and should reveal the presence of amoebic ulcers or, more frequently, the "raised crateriform pits" which, as pointed out by Cropper (1945) and Morton (1946), are pathognomonic of quiescent amoebic colitis in about half the number.

A moderate leucocytosis is almost invariably present, and a differential count should help to exclude a pyogenic infection by showing that the polymorphonuclear cells form, at most, only 75 to 80% of the total count. Radiological examination, preferably by screening, will often establish the fact that the right cupola of the diaphragm is elevated, and the degree of fixation is a reliable pointer as to whether abscess formation has occurred.

If operation is withheld during the first twelve to twenty-four hours the diagnostic difficulties are considerably reduced. Pain and tenderness tend to become localized, and as the result of reduction in the resistance of the abdominal musculature an enlarged liver may become palpable. Should reasonable doubt still exist at this stage and there be no urgent indications for operative intervention, a therapeutic trial of emetine is justified. This procedure usually helps to establish the diagnosis within twenty-four to forty-eight hours.

*Treatment.*—The treatment of acute hepatitis is standardized and the response is generally satisfactory. However, it should be emphasized that unless the primary and often symptomless bowel lesion receives attention, preferably by means of E.B.I. together with "quinoxyl" retention enemata, reinfection of the liver at a later date is likely.

#### Amoebic Liver Abscess

This condition is invariably preceded by a diffuse hepatitis, and during the early stages often presents similar diagnostic difficulties. A history of previous dysentery is obtained in less than half the cases, and even then the symptoms attributable to the colon may antedate the hepatic lesion by as much as fifteen years. Although general debility, loss of appetite, progressive weakness, and emaciation are characteristic, many cases are on record in which the diagnosis was established only after an apparently symptomless abscess had ruptured into the peritoneal cavity. The fact that pyrexia is often inconstant or absent and that adhesions following perihepatitis may prevent downward enlargement of the liver further helps to cloud the issue.

Leucocytosis is present in over 80% of cases and, as already mentioned in connexion with acute hepatitis, the differential count is of value in excluding a pyogenic infection. In addition, in the absence of secondary infection a total count in excess of 20,000 is suggestive of multiple abscess formation. Radiological screening should

in the great majority of cases place the diagnosis beyond dispute. The immobile tented appearance of the right cupola of the diaphragm, with obliteration of the costophrenic angle, is characteristic. A small effusion, often blood-stained during the early stages, is commonly associated with a variable degree of basal consolidation. In the type of case in which the pulmonary signs tend to overshadow the hepatic lesion this sero-sanguineous effusion is apt to suggest the diagnosis of pulmonary neoplasm.

*Treatment.*—Repeated courses of emetine will cure cases in which pus formation has been minimal, but as a rule it is necessary to empty the abscess cavity by aspiration through a large-bore needle. However, it is advisable to delay this procedure until such time as 3–4 gr. (0.2–0.26 g.) of emetine has been administered. Air instillation is of value as a means of utilizing radiological control, and is to be preferred to lipiodol. Should this procedure be employed, a volume of air equivalent to half the quantity of pus aspirated is introduced into the cavity. Thereafter the fluid level and the size of the cavity, as shown by a series of weekly x-ray examinations, will indicate the necessity or otherwise for further aspiration. Owing to the absorption of air it may be necessary to repeat the instillation at the end of three or four weeks.

After the adoption of the aspiration technique in preference to operative drainage the mortality rate fell from over 40% to approximately 6%. However, operation is still indicated under the following circumstances: in the presence of secondary infection by non-penicillin-sensitive organisms; when an abscess points on the abdominal wall or through an intercostal space; in resistant cases in which no improvement has occurred despite aspiration and repeated courses of emetine; and following rupture of an abscess (usually of the left lobe) into the peritoneal cavity.

Rogers (1922) showed that the high mortality rate following operative drainage was almost entirely due to toxæmia resulting from secondary infection of the large previously sterile cavity. It is possible, however, by means of close drainage, employing the fluid-seal principle, to eliminate this hazard to a large extent. The local and parenteral use of penicillin has further added to the safety of operative drainage. It should therefore be accepted that in the cases which do not respond to aspiration and emetine operative drainage should not be unnecessarily delayed.

*Results.*—Although in a small personal series penicillin was not employed, operative drainage performed on 11 cases resulted in one death, this being due to acute congestive cardiac failure occurring within six hours of operation under local anaesthesia. One case of rupture of an abscess of the left lobe into the peritoneal cavity was treated by laparotomy and drainage, with an uneventful recovery.

#### Perforations of Colon

This type of complication is usually described as being rare and almost uniformly fatal. There are, however, two distinct groups. In the first group the perforation is single and there is a marked tendency towards the formation of a localized abscess. These patients are often in good general condition, and a number of recoveries are on record. Four out of five of my own patients survived, following simple drainage of a pericolic retroperitoneal abscess. Treatment during the earlier stage is rather more difficult. The friability and induration of the colon usually necessitate an exteriorization procedure rather than closure of the perforation by suture.

In the second type the perforations are multiple and are associated with a severe general peritonitis, which, according

to the literature is invariably fatal. As most of the standard works on tropical medicine devote only a few lines to this type of complication, the following more detailed observations may be of value.

#### Multiple Perforations with General Peritonitis

This condition seems to occur mainly as a result of an acute or fulminating attack of dysentery superimposed on a long-standing chronic colitis of amoebic origin. The frequency of occurrence of this complication amongst African patients treated in Durban largely accounts for an over-all mortality rate of 10.8% in cases of amoebic dysentery (Elsdon-Dew, 1946).

The clinical picture is characteristic. The patient is admitted with acute dysentery, usually giving a history of numerous previous attacks over a period of some years. The toxic appearance, high temperature, tachycardia, and severity of diarrhoea tend to suggest a bacillary infection, but examination only reveals numerous free forms of *Entamoeba histolytica*, motile and haematophagous in type. Neither emetine nor chemotherapy appears to exert any appreciable effect, and deterioration is progressive. The earliest positive sign is that of gradually increasing tenderness, most pronounced over the caecum and pelvic colon. This is followed in two or three days by a moderate accumulation of intraperitoneal fluid. Guarding and rigidity are often fleeting in character and less marked than in cases with perforation of a single ulcer. Finally, sudden collapse, with subnormal temperature and signs of acute peripheral vascular failure, occurs.

Post-mortem examination, performed on 15 such cases, showed numerous perforations, with an average of five per case and ranging from 0.5 to 1.5 cm. in diameter. Distribution was generalized, the sites being the caecum and ascending colon, pelvic colon, hepatic and splenic flexures, and transverse colon, in that order of frequency. Gross thickening of the bowel wall was associated with diffuse ulceration and often a polypoid appearance, while the presence of numerous small areas of gangrene served to explain the multiplicity of the perforations. A peculiar feature of these cases, as distinct from the single-perforation variety, was the fact that the peritoneal fluid tended to be serous rather than purulent even when death had been delayed for three or four days after perforation. Of importance in relation to possible treatment was the finding that the omentum was usually adherent to the colon, and in many cases the perforations were completely sealed off. This fact suggested a comparatively slow process of erosion with peritoneal irritation, causing omental adhesion prior to the actual terminal thrombosis and perforation. Supporting evidence in favour of such an assumption is the fact that clinical examination usually revealed signs of peritoneal irritation and the presence of free fluid for one or two days before the final catastrophe.

**Treatment.**—In view of the depressing clinical picture and the findings at necropsy, it is obvious that the choice of a suitable operative procedure is a matter of some difficulty. In fact, the condition of the patient when first seen and the lack of response to resuscitative measures are usually sufficient to eliminate any idea of operation. Fortunately, it was found that when plasma transfusion was augmented by intravenous injection of adrenal cortical extract in 2-ml. doses repeated at hourly intervals a slight but definite improvement occurred, often just enough to allow of a minimal degree of operative intervention under local anaesthesia. The relatively extensive procedures such as exteriorization or repair by suture were precluded by the number and wide distribution of the perforations and the friable, necrotic condition of the colon, apart altogether

from any immediate disturbance to the patient entailed by their performance.

In view of the localizing action of the omentum, as demonstrated at post-mortem examination, and the absence of faecal content in the colon, as a result of the continuous diarrhoea, a simple procedure such as a "defunctioning ileostomy" appeared to be logical. Consequently, the following routine was adopted. A small muscle-cutting incision was made over the right iliac fossa, and the caecum, ascending colon, and, if possible, transverse colon were examined. Caecostomy was then performed, using a 3/4-in. (1.9-cm.) bore rubber tube, which was manoeuvred through the ileo-caecal valve into the ileum. In cases where induration, friability, and fixity of the caecum prevented this move the more time-consuming but also more efficient double-barrel ileostomy procedure was adopted. During the first twenty-four hours after operation adrenal cortical extract was given at four-hourly intervals. Intestinal decompression, intravenous fluid, electrolytes, and protein, and the administration of sulphathiazole constituted the routine post-operative treatment. Emetine was not given until the end of the first week.

**Results.**—Twelve cases were not treated by operation, but otherwise received the full routine. There were no recoveries. Out of 15 cases which received operative treatment seven recovered.

#### Affections of the Caecum

**Amoeboma.**—The differentiation between amoeboma and carcinoma of the caecum may be very difficult. If after full routine investigation there is still some doubt a full course of emetine should be given, preferably preceded by chemotherapy in order to reduce any secondary infection present. Only if resolution is complete, and confirmed radiologically, should the diagnosis be accepted. However, as pointed out by Naunton Morgan (1944), the degree of fibrosis present as a result of secondary infection may prevent a satisfactory response to emetine. In such a case it may be impossible to confirm the diagnosis except by microscopical examination following operative removal.

**Acute Typhlitis.**—Acute amoebic infection of the caecum may provide a picture indistinguishable from that of acute appendicitis. However, provided that this possibility is kept in mind, a careful history and examination will suggest the correct diagnosis in the majority of cases; but in some the element of doubt will necessitate laparotomy. Recent observers, dealing mainly with military cases of relatively short duration, tend to regard the incidence of acute appendicitis in association with amoebic typhlitis as negligible. However, experience in non-European practice does not altogether support this view, and one-third of my cases required appendicectomy for obstructive lesions. It should be emphasized, however, that obstruction or interference with the blood supply is the only indication for appendicectomy in the presence of active amoebiasis. If under these circumstances it is found necessary to proceed with the operation, certain additional safeguards are required in order to minimize the risk of the formation of faecal fistula. A double purse-string of silk or linen is used to invaginate the stump, the omentum is brought down to reinforce the suture line, and a soft rubber tissue drain is inserted into the right paracolic gutter. Emetine is administered immediately after operation.

**Results.**—In seven cases in which appendicectomy was performed convalescence was uneventful. Fourteen cases not subjected to operation showed dramatic response to emetine. Symptoms diminished after twenty-four hours, and were usually absent by the end of one week.

### Acute Intestinal Obstruction due to Amoeboma

A number of cases of intestinal obstruction were encountered in which amoebic dysentery appeared to be the major causative agent.

**Case 1.**—The patient, a boy aged 3½, had no history of dysentery. Examination revealed the presence of a tumour in the epigastrium, and a diagnosis of intussusception was made. Laparotomy revealed an inflammatory mass the size of a billiard ball arising from the wall of the transverse colon; it was adherent to the surrounding structures and the anterior abdominal wall. There was no pus formation, and the mass was mobilized without difficulty. In view of the degree of obstruction, a Mikulicz resection was performed, with drainage of the proximal loop by means of Paul's tube. Death occurred from bronchopneumonia seven days later. The inflammatory mass was found to be a non-specific granuloma, almost certainly amoebic in origin.

**Case 2.**—A woman aged 54 had a palpable mass in the right hypochondrium. There was no history of dysentery. Operation showed a granulomatous mass the size of an orange arising from the proximal part of the transverse colon and presenting signs of central softening. After mobilization it was found that the intestinal lumen was only partially obliterated. The mass was therefore marsupialized through a small wound in the flank, the omentum being used as an aid in sealing it off from the peritoneal cavity. Relief of tension following aspiration of the central abscess ensured the patency of the colon. After the closure of the original paramedian wound a drainage-tube was introduced into the abscess cavity. Convalescence was not complicated by the development of a faecal fistula, and resolution of the mass appeared to be complete.

### Acute Intestinal Obstruction due to Ileo-caecal Intussusception

During a period of less than a year four cases of intussusception were encountered in adults. In each of these operation showed chronic inflammatory thickening of the colon suggestive of chronic amoebic dysentery. Two cases, with histories of four and seven days, were too far advanced for effective surgical treatment, and death resulted soon after admission.

**Case 3.**—A girl aged 14 developed severe abdominal colic while in hospital under treatment for dysentery. Rectal examination carried out twelve hours later revealed the presence of an intussusception. In view of its extent operative reduction proved to be surprisingly easy, and the bowel was found to be viable. Convalescence was uneventful.

**Case 4.**—A man aged 32 came with nine days' history of abdominal pain. Operation revealed an ileo-caecal intussusception which had advanced as far as the middle of the transverse colon. Complete reduction proved to be impossible and the caecum was found to be gangrenous. The proximal opening formed by the walls of the ensheathing layer was therefore closed by means of mattress sutures; the addition of interrupted sutures to anchor the entering portion of the ileum completed the procedure, by which the devitalized bowel was excluded from the peritoneal cavity. Ileotransversostomy was then performed with some difficulty owing to the friability and chronic induration of the colon. After ten days the devitalized portion of the intussusceptum was passed as slough per rectum, and further progress was uneventful.

### Summary

The high carrier rate of *E. histolytica* among repatriated Service personnel is emphasized in relation to probable effects on post-war civilian practice.

Some of the surgical aspects of amoebiasis are discussed on the basis of experience gained in the treatment of African patients.

The results are given in a series of cases which include infection of the liver, perforation of the colon, acute infection of the caecum, and intestinal obstruction due to amoeboma.

My thanks are due to Mr. Arthur Copley and Mr. Algar Sweetapple for their advice and guidance in the treatment of these cases.

## IODINE AND FAILING LACTATION

BY

MARGARET ROBINSON, M.D., D.P.H.\*

An investigation into the part played by hormones in failing lactation was started under the auspices of the Medical Research Council on the suggestion of Prof. F. G. Young, D.Sc. The work began in 1944 in St. Thomas's Hospital by permission of Mr. J. M. Wyatt and Mr. A. J. Wrigley. It was extended in 1946 to University College Hospital by permission of Prof. W. C. Nixon and Prof. F. J. Browne. During this investigation it was discovered that large doses of dried thyroid gland caused a greater increase in milk yield per day in puerperal women than any of the other hormone preparations. This led to the trial of Lugol's solution in similar cases of failure to establish lactation in the puerperium. The results from the administration of Lugol's solution were found to be even more satisfactory. It was therefore decided to publish this preliminary report.

### Method

**Criteria of Failure to Establish Lactation in the Puerperium.**—In 500 untreated lactations in St. Thomas's Hospital the infants were test-fed each day during the puerperium, and were then followed up during the next six months. It was found that failure of lactation before the infant was 6 months old was rare where the total milk output on the fifth day of the puerperium had been at least 10 oz. (285 ml.) and on the tenth day of the puerperium at least 16 oz. (455 ml.). Nearly all the failures occurring in the first three months of lactation had had a total milk output either of less than 10 oz. on the fifth day of the puerperium or of less than 16 oz. on the tenth day. Therefore an output of at least 10 oz. on the fifth day of the puerperium or of at least 16 oz. on the tenth day was taken as the standard of establishment of lactation in the puerperium.

**Assessment of Milk Yield.**—From the fifth day of the puerperium until discharge from hospital the infants were test-fed at every feed. The sum of all the test feeds done in any one day gave the total output of milk for that day. The total output was calculated for each day of the puerperium. Owing to the fact that the patients were being discharged early from hospital on account of shortage of maternity beds, it was possible to treat only those patients who showed signs of failure on the fifth day—that is to say, those patients whose total milk yield as estimated from test feeds was then less than 10 oz. Treatment was started on the sixth day of the puerperium and continued either until the total daily milk yield had risen to 16 oz. a day or until the patient was discharged from hospital. After discharge from hospital the mothers reported with their infants when they were 4 weeks old. Owing to the shortage of beds and the distances the patients had to travel only two consecutive test feeds were

\* Working with a full-time grant from the Medical Research Council at St. Thomas's Hospital, London, and at University College Hospital, London.

possible. The times of these two test feeds were either 10 a.m. and 2 p.m. or 12 noon and 3 p.m. The average of the two test feeds was multiplied by five or by six, according to whether the infant was being fed four-hourly or three-hourly. This gave a rough estimate of the output of milk per day in the fourth week of lactation, and made it possible to compare the results from treatment with Lugol's solution with the results produced by other treatment.

**Procedure.**—A total of 99 cases of failure to establish lactation in the puerperium were investigated. Seventy-two were used as controls and 27 were treated with Lugol's solution. All the infants were test-fed on the fifth day of the puerperium. If, according to the criteria mentioned above, failure to establish lactation was present on the fifth day, treatment was begun on the sixth day of the puerperium. In the case of saline injections the treatment lasted for five days. In the case of massage and treatment with Lugol's solution it lasted until the patient was discharged from hospital or until the output of milk per day had reached 16 oz. Test-feeding started on the fifth day and continued until the patient was discharged from hospital, on the tenth or fourteenth day. The subsequent course of each lactation was followed up by two consecutive test feeds done when the infant was 4 weeks old.

**Materials.**—Six drops of Lugol's solution (5% iodine in 10% aqueous potassium iodide) in milk were given by mouth twice a day. This treatment was continued until the yield of breast milk had risen to 16 oz. a day. Twenty-seven cases were treated. Seven had to be discarded for the following reasons: (1) Three of the infants were premature and were not fit to be test-fed. It was found impossible to obtain an accurate estimate of the daily amount expressed. (2) Three mothers had painful nipples. Breast-feeding had to be stopped within twenty-four hours of starting treatment, as the patients refused to go on breast-feeding because of the pain. (3) One mother had had lumpy breasts, which became painful after twenty-four hours' treatment with Lugol's solution. The Lugol's solution had to be stopped, and treatment with oestrogens was begun. By the time the breasts were rendered soft and painless with the oestrogens it was too late to start treatment with Lugol's solution, because she had to be discharged on account of the shortage of maternity beds. The infant was bottle-fed.

It has been found that thickened, tender, and lumpy breasts that produce a scanty secretion of a thick fatty material are only made worse by treatment with Lugol's solution, and the amount of secretion is not increased. If, however, the lumps and tenderness are removed by giving 5 mg. of stilboestrol four-hourly by mouth, then Lugol's solution will increase the output of milk and the lumps do not recur.

**Controls.**—(1) Eleven cases were given breast massage as advocated by Randall (1943). Treatment started on the sixth day and continued until the thirteenth day of the puerperium. (2) *Physiological saline.*—Nineteen cases were treated with intramuscular injections of 1 ml. of physiological saline. The injections were given into alternate buttocks on five consecutive days, starting on the sixth day of the puerperium. (3) *No treatment.*—Twenty-one cases were given no treatment. Test-feeds were done from the fifth day until the thirteenth day of the puerperium. In four of them secretion had completely ceased before the thirteenth day. (4) *Normal lactation.*—Twenty-one women who had no difficulty with lactation were test-fed from the fifth day of the puerperium until the thirteenth day, and then at intervals up to the sixth month of lactation. The mean output of these 21 women was calculated for each day of the puerperium.

## Results

The results are set out in a table, which gives the mean total output per day in each group of patients during the puerperium and at one month after parturition. In the group that were given Lugol's solution four patients were discharged from hospital on the tenth day and two on the twelfth day. Eight have since reported when their infants were 4 weeks old. The control groups were all investigated in St. Thomas's Hospital, and were therefore not discharged until the fourteenth day of the puerperium. All the controls reported when their infants were 4 weeks old. Among the cases treated with Lugol's solution only eight have as yet reached the age of 4 weeks.

From the table it can be seen that the patients made less effort to feed their infants when they were given no treatment than when they were given either massage or daily injections of physiological saline. The increase in output is greatest in the group of patients who were given Lugol's

Table showing the mean daily milk yield

	No. of Cases	Day of Puerperium											At Four Wks.

\* Beginning of treatment. † End of treatment.

solution. On the thirteenth day of the puerperium the mean output of the patients taking Lugol's solution was not much less than the mean output of the normally lactating women. No iodism was encountered. All but one of the infants in this group were discharged fully breast-fed.

In this one case the mother had at no time from the birth of her infant to the seventh day of her puerperium produced more than a few drops of thick yellow fluid. On the second day her breasts became thick and rosy. She was treated with oestrogens from the third day onwards. Not until the seventh day did her breasts feel soft and empty on palpation. Treatment with Lugol's solution was therefore not begun until the seventh day. On that day she produced one teaspoonful of milk, which was manually expressed; on her thirteenth day she produced 7 oz. (200 ml.), as calculated from test feeds on that day. The infant was sent out partly breast-fed, as owing to the shortage of maternity beds it was not possible to keep the mother in longer for further treatment.

The three mothers who had premature infants too small to test feed were all discharged from hospital with more than enough breast milk to feed their infants. They had had about seven to ten days' treatment with Lugol's solution.

**Treatment of Failing Lactation After End of Puerperium.**—Collection of these cases for treatment with Lugol's solution has only recently begun. So far only nine patients have started treatment. 10 min. (0.6 ml.) of Lugol's solution was given by mouth in milk three times a day. Three of the nine infants were fully breast-fed after three weeks' treatment. In two cases the output of milk per day failed to rise. Four patients defaulted. In the successful cases the increase in output ranged from 5 to 9 oz. (140 to 255 ml.) per day.

## Conclusions

Failure to establish a satisfactory milk output in women is apparently due to two deficiencies—oestrogens and iodine. The need for oestrogens to control the milk flow through the breast is present in the first four days after labour; the need for iodine to increase the output of milk

is present from the fourth day onwards. These deficiencies may be present singly or together. If together, the oestrogens must be given first. Until the oestrogen deficiency is cured it is often difficult to tell whether there is an iodine deficiency. Giving Lugol's solution to a case with an oestrogen deficiency untreated only aggravates the condition and does not increase the milk output. The sign of an oestrogen deficiency is lumpy breasts with a thick yellow secretion that is difficult to express. The sign of an iodine deficiency is soft empty breasts with a scanty secretion of milk. Both oestrogens and Lugol's solution are safe and easy to give. The duration of the treatment is short. The treatment does not upset either the mother or the infant.

The number of patients with older infants who have so far been treated with Lugol's solution for failure of lactation are too few for any conclusions to be drawn. However, the outlook is hopeful, as in three cases out of five in which the mothers took the Lugol's solution for three weeks the infants became fully breast-fed. The sign that the infant has become fully breast-fed is a sudden large increase in the weekly weight gain and an increase in the number of stools. The stools return to normal when the bottle-feeds are stopped.

### Summary

Twenty cases of failure to establish lactation in the puerperium were treated with Lugol's solution. The mean output per day increased by 300%. One-third of a small number of failures of lactation in mothers with older infants have responded to Lugol's solution.

I am indebted to the Medical Research Council for a personal grant and to Prof. F. G. Young for his help and criticism. I wish to thank the medical and nursing staffs of St. Thomas's Hospital and University College Hospital for their co-operation.

## ACUTE DILATATION OF THE STOMACH

BY

B. MARKOWSKI, M.D.

Surgeon Commander, Polish Navy

Most recorded cases of acute dilatation of the stomach have appeared as post-operative or post-anaesthetic complications. Only a few authors have described acute dilatation caused by overloading of the stomach with food. Four such cases were admitted to my surgical department within a short period.

### Case 1

A Russian prisoner-of-war aged 20 was admitted to hospital in February, 1942, with frostbite of the lower limbs. His general condition was very poor and he was emaciated and pale. The lungs, heart, and alimentary system showed no abnormality. There was wasting of the upper and lower limbs with bilateral partial paralysis of the radial nerve. Both feet showed moist gangrene. He had been treated by removal of the necrotic parts of both feet and by general anti-infection therapy. On Nov. 5, 1942, after having eaten a larger dinner than usual (about 1 litre of soup and ten potatoes), he complained of abdominal pain.

*Condition on Examination.*—Pulse rate 60; temperature 98.6° F. (37° C.). Both feet amputated but amputation stumps unhealed and considerable purulent discharge. Left thigh oedematous. Heart and lungs normal. Abdomen dis-

tended, particularly the epigastrium, but not rigid; slight epigastric tenderness; liver and spleen not enlarged; on percussion areas of dullness, and on auscultation peristaltic sound were heard. There had been no passage of flatus since the onset of symptoms three hours before. The patient vomited frequently but only small amounts. He was sleepy, apathetic and complaining of slight abdominal pain. A diagnosis of acute dilatation of the stomach was made.

*Treatment.*—A stomach tube was passed, and an injection of "prostigmin," intravenous hypertonic saline, and an enema were ordered. After three hours repeated attempts to evacuate the stomach had failed. The abdominal distension was increasing and the pain was more severe. Fluid injected down the tube to dilute the stomach contents did not return. After six hours of the same treatment there was still no evacuation of stomach contents. The patient's general condition was worse, with increasing pain and much retching. The pulse rate was now 90. Some flatus had been passed, but with no reduction in the abdominal distension.

The stomach tube was then passed once more, but with the patient lying on his side with the knees bent. There was an immediate good result and emptying of the stomach proceeded rapidly. The total amount evacuated was 8 litres, which was mainly fluid but mixed with a certain amount of digested and undigested food, mostly potatoes. After this the patient felt considerable relief and went to sleep. A few hours later he awoke feeling much better; flatus was passed normally. He remained in hospital for a further twelve months for treatment of his legs, but during this period he had no further stomach trouble.

### Case 2

An Italian prisoner-of-war aged 30 was admitted to hospital on March 17, 1944, with a diagnosis of acute appendicitis. In 1941 he had had malaria and he also gave a history of several attacks of bronchitis. For the last three and a half months he had worked very hard in a factory. As a result of this he became so exhausted that he was admitted to the sick bay for a special diet and nursing. On March 17 his diet was as follows:—

7 a.m.—Half litre "ersatz" tea and 100 g. of biscuits.  
10 a.m.—One piece (100–150 g.) of bread and two potatoes.  
12 a.m.—One and a quarter litres of turnip soup.  
2 p.m.—Half litre of skimmed milk and two biscuits.  
4 p.m.—About one litre of potato purée.

After eating these meals he felt slight abdominal pain and noticed some distension of the abdomen. In spite of this he had a further meal at 6.30 p.m. consisting of half a litre of potato purée and about 500 g. of bread. Almost immediately he developed severe abdominal pain and distension, with dyspnoea and difficulty in passing flatus.

*Condition on Examination.*—At 9 p.m. on March 17 his pulse rate was 109. He was well-built but emaciated. Rapid shallow respirations. No vomiting, and only a small amount of flatus passed. Lips and tongue were rather dry. Lungs normal; apex beat displaced upwards. Limbs slightly oedematous.

There was marked distension, particularly in the upper abdomen, but no rigidity; some tenderness in the epigastrium. One seemed to feel the outlines of the distended stomach but this was not definite. On percussion the abdomen was tympanitic; the liver and spleen were not obviously enlarged. Normal peristaltic sounds were heard on auscultation. A diagnosis of acute dilatation of the stomach was made.

*Treatment.*—The patient was placed in the lateral position with the knees bent and a stomach tube was passed. He was also given an enema, an intravenous hypertonic saline, and subcutaneous saline. The first and second attempts at lavage failed, but after pouring in a quantity of water to dilute the stomach contents about 4½ litres (with potatoes, vegetables, and bread) were removed. During each of the next five washouts 1–1½ litres of fluid gastric contents were evacuated together with much gas. After two enemata, within three hours of admission to hospital, the patient had a good movement of the bowels.

By midnight he felt well. There was frequent passage of flatus, the abdominal distension had disappeared, and the belly wall was soft. Some epigastric tenderness persisted and the pulse rate was now 86. Thereafter his recovery was uneventful. A radiological examination on April 2 showed "gastro-entero-typonia and -ptosis." He was discharged from hospital on April 8.

### Case 3

An Italian prisoner-of-war aged 19 had had synovitis in 1925 and frequent "indigestion" during recent years. After a long period of starvation he had eaten several meals in the course of one day. This was on Dec. 16, 1943, when his meals were as follows:

6.30 a.m.—Three-quarters of a litre of "ersatz" coffee.

10 a.m.—Half a litre of coffee, 200 g. of bread, 15 pieces of carrot.

12 a.m.—Vegetable soup and meat—2½ litres.

4 p.m.—One litre of milk soup and 15 pieces of carrot.

He then had abdominal pain, but in spite of this at 5.30 p.m. he ate 450 g. of bread, 30 g. of margarine, and 50 g. of biscuits. This exceptionally good food was given, accidentally, to encourage the patient to enlist in an Italian Brigade for the German Army. A few hours after the last meal there was further abdominal pain and he vomited. There was no passage of flatus and no bowel movement after the onset of pain. The next morning, Dec. 17, 1943, he was transferred to hospital with a diagnosis of appendicitis.

**Condition on Examination.**—He was a pale, emaciated, sthenic type; pulse 90 and irregular. Lungs normal and heart displaced upwards. There was marked abdominal distension and slight rigidity; on percussion the abdomen was tympanitic. The liver and spleen were not enlarged. No peristaltic sounds were heard on auscultation. His urine was normal, and he had a leucocyte count of 16,000 per c.mm. During the examination he lay on his back with his knees drawn up, complaining of abdominal pain, dyspnoea, and failure to pass flatus. He was diagnosed as a case of ileus following acute dilatation of the stomach.

**Treatment.**—The patient was placed in the lateral position with the knees bent and a stomach tube was passed. He was also given an enema, intravenous hypertonic saline, subcutaneous saline, and an injection of prostigmin. After three hours of this treatment repeated attempts to empty the stomach all failed. His pain increased and signs of toxæmia developed with a rapid irregular pulse; his general condition became worse. Immediate operation was then undertaken.

**Operation.**—Under spinal anaesthesia a midline incision was made. On opening the abdomen the small bowel was found to be distended, particularly in its proximal part. The distal part of the small bowel and the large intestine were normal in appearance. The stomach was distended and immobile, extending downwards and pressing on the duodenum. There was no other obvious obstruction either inside or outside the stomach and intestines. There was no sharp line of demarcation between the normal and the distended bowel. There was much free fluid in the abdomen.

After lifting the stomach the bowels were successfully evacuated and the distension almost disappeared. The appearance of the stomach, however, remained unchanged. It was decided to close the abdomen and to resume conservative treatment. During the suture of the wound the patient had a good action of the bowels. Energetic conservative treatment was then resumed. His general condition improved on the following day but deteriorated on Dec. 19. No flatus was passed and the patient vomited, bringing up faecal fluid. There was marked abdominal distension and severe pain.

**Operation.**—The abdomen was opened at McBurney's point under local anaesthesia. The distended caecum presented in the wound and caecostomy was performed. There was free drainage of the bowel contents and for three days improvement in the general and local condition continued. The patient felt well and did not vomit.

On Dec. 22 there was again a sudden deterioration in his general condition with symptoms of small bowel obstruction. Attempts at evacuation through the caecostomy failed.

**Operation.**—Under local anaesthesia at a third operation an incision was made in the left side of the abdomen. Enterostomy was performed by inserting a "T" drainage tube in the small bowel. A considerable amount of liquid and gas was expelled. The patient's condition after operation was satisfactory. There was good drainage through both tubes and the bowels opened normally as well. During the next two months there was a remarkable improvement. The patient's appetite increased and he put on weight. Both enterostomy openings were then closed and he was discharged cured.

### Case 4

This prisoner-of-war was admitted to hospital with a diagnosis of peritonitis. He had a history of malaria and he had suffered burns of the feet twenty days before admission. After a period of starvation he had eaten in the course of one day 2 litres of soup, 300 g. of bread, 1 litre of coffee, and some potatoes. This was on Feb. 27, 1944, and the next morning he noticed some distension of the abdomen. In the afternoon he developed epigastric pain and difficulty in passing flatus; he also vomited. He was then examined by the camp medical officer and transferred to hospital.

**Condition on Examination.**—He had a pulse rate of 68 and was well built but emaciated. There were enlarged lymphatic glands in the groin. His tongue was moist and he had many carious teeth. The lungs were normal and the heart was displaced upwards. There was marked abdominal distension, particularly in the epigastrium. The distended stomach appeared to be outlined through the abdominal wall, but this was not definite. There was no rigidity, and on percussion the epigastrium was tympanitic. The liver and spleen were not enlarged. There was slight tenderness in the epigastrium and no clinical evidence of peritonitis.

On the dorsum of the left foot there was the scar of a recent burn and the leg was slightly swollen. The patient complained of pain in the abdomen, and particularly in the epigastrium. He was drowsy and apathetic, and was retching and vomiting. He was diagnosed as a case of acute dilatation of the stomach.

**Treatment.**—A stomach tube was passed with the patient in the lateral position, and an enema and intravenous hypertonic saline were given. Repeated attempts at evacuation of the stomach failed and water which was intended to dilute the stomach contents was not returned. The patient became drowsy and tired and after six hours of unsuccessful treatment it was decided to operate.

**Operation.**—Laparotomy was performed through a midline incision under spinal anaesthesia. There was free fluid in the abdomen with distension of the upper part of the small intestine. There was no sharp demarcation between the distended and the normal bowel. The stomach was grossly distended and immobile and was pressing on the duodenum. Apart from this there was no evidence of obstruction of the bowel, and the other abdominal organs appeared to be normal. An attempt was made to empty the stomach by aspiration, but only a little gas was removed. An attempt to "milk" the contents of the bowel was also unsuccessful. A jejunostomy was therefore performed and the abdomen closed. A large amount of fluid and gas was removed through the jejunostomy tube.

**Post-operative Treatment.**—Further gastric lavage was undertaken and a hypertonic saline and an injection of prostigmin were given. There was obvious improvement within a few hours of operation. Flatus and faeces were passed normally as well as through the tube and the distension subsided. On the next day there was a good bowel movement normally. Three days later an attempt to close the jejunostomy gave rise to symptoms of ileus. After eight days the operation wound was completely healed and the patient felt well. After two months' treatment (including operative closure of the jejunostomy) he was discharged.

### Aetiology and Diagnosis

In these four cases acute dilatation of the stomach appeared after eating an increased amount of food. In Cases 2 and 3 the amount of food eaten was large, but the same amount eaten by many normal people would not cause any complication. In Cases 1 and 4 the amount was not larger than the average meal taken in normal circumstances. There must, therefore, have been some predisposing cause.

All our patients were emaciated and were admitted to hospital after a period of starvation. This starvation I consider to be a predisposing cause, but the part it plays is not clear. It is possible that the acute dilatation follows a chronic dilatation of the stomach. In other words, a sudden intake of food causes paralysis of the already weakened walls of the stomach. Chronic dilatation of the stomach, due to the prolonged intake of large amounts of food of poor calorie value, was so common that we used to call it "the occupational disease of prisoners-of-war."

I would not venture to discuss more fully the part played by starvation as a predisposing cause, but I would stress the fact that in an emaciated and starving individual acute dilatation of the stomach may be precipitated by the intake of a comparatively small amount of food, an amount which in a normal individual would cause no disturbance. This observation, I think, is important from the point of view of aetiology.

Clinically there were three signs of practical importance: (1) drowsiness; (2) objection to the passing of a stomach tube, and particularly to the pouring in of water to dilute the stomach contents; and (3) failure of fluids to return from the stomach. These small points may be useful in the differential diagnosis from other causes of ileus.

### Methods of Treatment

In each of these cases, immediately after the diagnosis had been made, treatment was begun. In the first two cases gastric lavage through a stomach tube was successful. It is important, however, to adjust the position of the patient, or failure will result. The patient should be in the left lateral position with bent knees.

In the two other cases conservative measures failed. Intubation through the nose also failed, probably because the stomach contents were not sufficiently fluid. In both cases the pain increased and toxæmia developed. This led to operation, an additional indication being the possibility of an error in diagnosis. It was known, too, from the literature that sudden death might occur during a prolonged period of dilatation of the stomach, and postponement of the operation might be dangerous.

Laparotomy in both cases showed only distension of the stomach and no obstruction either inside or outside the stomach and intestines. It was interesting to find no clear demarcation between the distended and the normal jejunum. I did not perform gastrotomy, because I considered that incision of the stomach walls might have an adverse effect. Evacuation of the stomach is important in conservative treatment but it is not the essential aim at operation; indeed, complete evacuation is impossible, because of the hypersecretion which accompanies dilatation. Puncture with a wide-bore needle showed that the atonic stomach contained much fluid and only a small amount of gas. An attempt to evacuate the intestine by "milking" it was followed by bowel movements just after operation, or even during the operation.

In Case 3, after temporary improvement, the general condition deteriorated, and it was necessary to operate again. I performed enterostomy, which caused evacuation

of the stomach and intestines, and doubtless helped to restore the tone of the stomach walls. In Case 4 the patient had good bowel movements normally half an hour after operation. It is possible that further delay would have rendered operation unnecessary, but lack of experience and the presence of signs of toxæmia compelled us to operate.

### Danger of Gastrotomy

While compiling this report I found the bed ticket of a German soldier treated in a German hospital. The most important points in his case history are summarized.

Aged 43. Sudden onset of abdominal pain at 6 p.m. on Dec. 11, 1942. Admitted to hospital at 10.45 p.m. Stated that he had never had abdominal pain previously and that he did not eat too much. Clinical examination showed ileus.

At operation the intestines were found to be distended and the stomach grossly distended. Puncture of stomach and removal of gas. Gastrotomy and removal of contents (three kidney dishes of stinking fluid mixed with potatoes, meat, and carrots). Suture of stomach. Suture of abdominal wall. Condition after operation grave. Died at 4 p.m. on Dec. 13.

Necropsy revealed acute dilatation of the stomach and intestines, which had caused circulatory failure. Cause of dilatation—overloading of stomach.

In this case gastrotomy did not prevent the patient's death. Other cases in the literature emphasize the danger of gastrotomy. I suggest that the danger of gastrotomy can be avoided and satisfactory results obtained by enterostomy and energetic conservative measures. Conservative treatment alone may be insufficient and dangerous in some cases; enterostomy may then be helpful.

### Summary

Four cases of acute dilatation of the stomach in prisoners-of-war are described.

In emaciated and starving individuals acute dilatation of the stomach may be precipitated by the intake of a comparatively small amount of food.

Clinical signs to which attention is drawn include drowsiness, objection to gastric lavage, and the failure of fluids to return from the stomach.

Lavage with the patient in the lateral position with knees bent was successful in two cases. In the other two cases enterostomy was performed. Gastrotomy is dangerous.

My thanks are due to Mr. Ch. Langmaid, F.R.C.S., for help and translation.

A circular from the Ministry of Education to local educational authorities on the selection of medical officers for the examination of educationally subnormal children states that after Dec. 31 of this year the medical officer must have been selected by the authority on the advice of their school medical officer as a suitable person to have been given an opportunity for observing examinations by an approved medical officer, have attended, after such observation, an approved course of practical and theoretical instruction, and after a further period of observation be recommended to the Minister of Education on the advice of their school medical officer for approval. In exceptional circumstances the Minister may waive these conditions. The approved courses of training are conducted by the London University Extension and Tutorial Classes Council in conjunction with the National Association for Mental Health. Three courses have been arranged for 1947, and it is likely that a similar number will be held in 1948. Candidates have been selected for the first two courses this year; applications have been invited for the September course.

## BILE PERITONITIS IN INFANCY

BY

F. DENIS HINDMARSH, M.S., F.R.C.S.

*Temporary Assistant Surgeon, Royal Victoria Infirmary,  
Newcastle-upon-Tyne*

So far as I have been able to ascertain this is the first case of bile peritonitis in infancy occurring without trauma to be reported in this country. Caulfield (1936) published two similar cases in America, and stated that severe trauma had caused rupture to the gall-bladder or common duct in all the reported cases he could find.

## Case Report

The patient, a baby girl aged 1 year and 10 months, was admitted to the children's department of the Royal Victoria Infirmary on Nov. 28, 1946. The child had been well until 36 hours before admission. She woke her parents up in the early morning of the 27th, was restless but did not cry. She had complete loss of appetite, and vomited once towards evening. Her bowels moved four times during the day, but the motions were apparently normal in colour. On the day of admission she again vomited, but slept fitfully and did not appear to be in much pain.

On admission at 7.30 p.m. she was collapsed, her extremities were cold and cyanotic, her respiration was rapid, but her chest showed no abnormal physical signs. The abdomen was slightly distended, with some generalized tenderness. The child's condition was so poor that it was decided to give an intravenous transfusion of plasma and to re-examine her when some improvement had occurred. Consequently 200 ml. of plasma was given in about two hours, by which time her condition was much improved. A further examination showed a somewhat distended abdomen, with generalized tenderness, especially in the upper abdomen. There were diminished resonance in the flanks and tenderness per rectum. The temperature was 103° F. (39.4° C.), pulse 150, and respirations 50. The white cell count was 31,500 per c.mm. A diagnosis of peritonitis, probably associated with appendicitis, was made.

The abdomen was opened through a right paramedian paramedian incision. A large quantity of bile-stained fluid escaped from the peritoneal cavity; this was not measured, but it was estimated to be about 400-500 ml. The incision was enlarged upwards, and a rapid inspection of the gall-bladder and common duct did not reveal any gross abnormality. There was some retroperitoneal oedema, and flecks of lymph were present in the region of the duodenum. As the child's condition was not very satisfactory simple drainage in the region of the common duct was performed. Culture of the bile proved sterile. The origin of the bile being uncertain it was decided to aspirate the stomach post-operatively, giving 100 ml. of saline every three hours intravenously. This treatment was continued until Nov. 30. Bile was still draining from the wound. The drainage-tube was removed on the seventh post-operative day, and by Dec. 10 the wound was almost healed and the bile drainage had cleared up.

The patient was discharged from hospital on Dec. 11, but was readmitted on Jan. 2, 1947, complaining of abdominal pain and vomiting; this, however, settled down very quickly. A cholecystogram revealed a gall-bladder which seemed to function normally. The child was discharged again, apparently well, on Jan. 8.

## Discussion

Bile peritonitis following trauma to the liver is relatively common. I saw two cases due to bomb-splinter wounds while serving with a field surgical unit. Both these cases recovered. I have also seen bile peritonitis associated with crush injury and laceration of the liver; this patient survived the onset of bile peritonitis but subsequently died of uraemia.

Most surgeons have seen a case of bile peritonitis in adults without apparent cause. One case reported to me

by Mr. T. A. Hindmarsh (personal communication) had two such attacks, separated by an interval of seven years' normal health. It is certainly not the fatal condition it is sometimes said to be, unless it is associated with gall-bladder disease.

It is thought that in the above case there must have been a small cyst or aberrant duct which had ruptured; the abnormality must have been a minor one, as recovery was rapid and apparently complete. As an alternative cause, in view of the retroperitoneal oedema, I considered the possibility of a duodenal sacculi which had ruptured, but the subsequent behaviour of the case ruled this out of court. Remarkable features are the leucocytosis and the pyrexia, suggesting an inflammatory cause; as already stated, however, the bile was sterile.

Caulfield's cases were somewhat similar to the above case: both his cases occurred in male infants under six months old, but the onset was more gradual, the babies had no abnormal temperature, and they were jaundiced. It is interesting to notice that in the surviving case simple drainage in the region of the common duct, such as I performed, was sufficient apparently to cure the condition. Caulfield came to the same conclusion—that there must have been some minor abnormality of the ducts. In his other case no operation was performed, and it was found post mortem that there was a congenital stricture of the common duct.

## Summary

A case of bile peritonitis in early childhood is described. It is claimed to be the first reported case in this country. Simple drainage in the region of the common duct effected an apparent cure.

The possible aetiology of the case is discussed.

Comparison is made with Caulfield's cases.

I would like to thank Prof. J. C. Spence for permission to publish this case, and Miss M. Swinburne and other members of the Children's Department for their co-operation in the pre- and post-operative treatment.

THE BERGER-KHAN TEST FOR  
SYPHILIS

BY

J. H. FODDEN, M.D.

AND

E. J. MADDOX, F.I.M.L.T.

(From the Donaldson-Hudson Pathological Laboratories,  
Shrewsbury)

Whilst using the dye isamine blue as an indicator in serological tests for syphilis Berger (1943) found that certain other dyes when mixed with a suitable alcoholic heart extract caused, in syphilitic sera, not only the formation of coloured precipitates but an increase in the sensitivity of the reaction. This sensitivity was directly proportional to the amount of dye present in the antigen. Janus green and Victoria blue were the dyes of choice, as they appeared to be the best sensitizers and in their presence heavy flocculation rapidly occurred. The precipitate was intensely coloured and took up all the dye from the solution, leaving a water-clear supernatant fluid. Sera containing amounts of syphilis antibody too small to react with a given antigen without dye showed marked flocculation in the presence of Victoria blue or Janus green. Berger pictured the sensitizing action of the dye as an antibody-like effect which had been deprived of its specificity and which was

conditioned by the presence of a specific factor in syphilitic serum. In the dye test he devised for syphilis Berger chose Victoria blue because very fine dispersion of the alcoholic antigen could be obtained with this dye as compared with Janus green.

For the purpose of the investigation this laboratory carried out in triplicate 970 routine serological tests for syphilis. The washed-antigen method of Price (1946) was also used for a short time, but in our hands appeared to be too sensitive. We therefore discontinued parallel tests to avoid undue complications in the interpretation of results.

The standard antigen for the Kahn test as supplied by the Ministry of Health Special Laboratories was used. The preparation of reagents and the technique of the test as recommended by Berger were carried out in the following manner.

A stock antigen (which keeps for at least a year at room temperature) is prepared thus: To 10 parts of standard antigen containing 0.6% of cholesterol and having a titre of 1 + 1.2 add 1 part of tinct. benz. co. B.P. To 10 ml. of this mixture add 17 mg. of Victoria blue 4R (Gurr). The container should be kept well stoppered.

#### Method of Test

(1) Pipette 1 part of the stock antigen (0.1 ml.) into the bottom of a dry tube. (2) Add 10 parts (1 ml.) of 0.85% sodium chloride solution rapidly to the tube from the pipette. This dispersed antigen is sufficient for at least thirty tests, and can be used at once or during any time on the day of preparation. It should be shaken immediately before use. (3) Place on a prepared glass slide one drop of the serum to be tested and add a drop of equal size of the dispersed antigen. (4) Mix the drops with a glass rod, rock the slide for two minutes, and read results immediately. (Note: To help in the rapid handling of large numbers of sera use may be made of ordinary clear glass sheets with rows of rings painted on the surface. A convenient size would be 8 in. by 10 in. (20 by 25 cm.), as this allows four rows of six rings,  $1\frac{1}{4}$  in. (3.2 cm.) in diameter, per plate. High-gloss black enamel has proved most useful and durable under test.) (5) The results are read macroscopically, and as a distinct aid to easy reading the slide is held over a sheet of white paper. Positive reactions show large deep-blue floccules easily visible in a water-clear fluid. Negatives at two minutes show no flocculation whatever, the mixed drop remaining quite homogeneous and of a sky-blue colour.

It is the custom in this laboratory when reading positive Kahn tests to assign to each result a numerical indicator to express the strength of the positive reaction as judged by the degree of flocculation. The standard Kahn method often showed lower numerical grading, and in the case of weak positives by the other methods some were missed. This was particularly marked when dealing with old treated cases. Difficulty in reading weakly positive standard Kahn tests is overcome in the Berger-Kahn test by the pronounced staining of the floccules which occurs. The strongly positive sera are easily read, as the floccules in this case are very large and absorb the whole of the dye. In our experience, whenever this result was obtained we always noticed that the Wassermann reaction read 2 + or 3 +. We wish to emphasize that every one of our positive Wassermann results gave a positive reaction with the Berger-Kahn test.

We are at present observing the results of this method upon cerebrospinal fluid from cases of neurological syphilis and hope to report separately upon a series of such tests.

#### Comment

The reaction should be read at two minutes, and not four minutes as recommended by Berger, as reading at the latter time yields a high proportion of mixtures showing very faint granularity, which can lead to some confusion.

Berger made no reference to the graduation in size of the blue floccules in assessing the strength of a positive result. We found it quite easy to grade positives on the size of particles given by the Berger-Kahn test. We found such gradation in particle size very constant and most helpful.

## Medical Memoranda

### Arsenical Dermatitis Successfully Treated with BAL

As the treatment of this condition has always been difficult and rather unsatisfactory I thought these two cases worth recording.

#### CASE REPORTS

**Case 1.**—A labourer aged 27 first attended the V.D. clinic at the Royal Victoria and West Hants Hospital, Bournemouth, on June 12, 1946. He then had a large ulcer at the base of the glans penis, and dark-ground examination revealed the presence of *Treponema pallidum*. The Wassermann reaction was negative. Treatment was started at once with 300,000 units of penicillin twice daily for five days, together with N.A.B. and bismuth. He was given 0.45 g. of N.A.B. twice weekly for four injections, followed by 0.6 g. twice weekly for a further eight injections—a total of 6.6 g. of arsenic. Bismuth, 0.2 g. twice weekly, was given for six weeks, total 2.4 g. The full course was completed on Aug. 17. On Aug. 28 an erythematous rash with desquamation appeared on the limbs and trunk. The patient was given daily intravenous injections of 6 ml. of calcium thiosulphate. There was no improvement on Sept. 4; he then had oedema of the hands, fissuring of the palms with some exfoliation, and similar fissures at the ankles and on the soles of the feet. There was oozing from all fissures. On Sept. 5 treatment with 2 ml. of BAL (British anti-lewisite) intramuscularly every hour was started. The next three days he had 2 ml. twice a day and then 2 ml. a day for two days. On Sept. 11 there was desquamation and the fissures were drying up. On the 18th oedema of the hands was much less and the fissures were healed. On the 25th there were slight cracks on the palms of hands and soles of the feet. By Oct. 9 the hands and feet were quite healed and the patient was back at work.

**Case 2.**—A housewife aged 26 first attended the V.D. clinic on Sept. 18, 1946, with a secondary syphilitic rash involving the arms and trunk (Wassermann++, Kahn +++). There was some dental sepsis, but as she was seven months pregnant it was thought advisable to prescribe arsenic and bismuth as well as penicillin. She was given 600,000 units of penicillin daily from Sept. 25 to Oct. 1; three injections of 0.45 g. and five of 0.6 g. of N.A.B. (a total of 4.35 g. of arsenic) and eight injections of 0.2 g. of bismuth between Sept. 25 and Oct. 23. On Oct. 30 erythematous patches with oedema were noticed on the buttocks, and smaller patches were seen at the bends of the elbows. Calcium thiosulphate, 6 ml., was prescribed twice weekly till Nov. 15. As there was no improvement BAL was given from Nov. 22 to 25. Owing to her confinement the patient did not attend again until Jan. 22, 1947, when no rash was to be seen, and she stated that it had quite disappeared before her confinement on Dec. 17.

It seems to me that BAL may well be the answer to the syphilologist's prayer, for, instead of cases of arsenical dermatitis being in hospital for weeks at a time, they may now be treated as out-patients. The response is most dramatic, as the rash begins to clear as soon as treatment is started.

I would like to thank Dr. R. H. S. Thompson, of the Department of Biochemistry, Oxford, for his help and interest, and for supplying the BAL; also my colleague, Dr. L. Heasman, for his help in treating these cases.

J. LAWRENCE REEVE, M.R.C.S., L.R.C.P.,

Director of Venereal Diseases Clinic,  
Royal Victoria and West Hants Hospital, Bournemouth.

## Reviews

### TEXTBOOK OF PHYSIOLOGY

*Lehrbuch der Physiologie.* By Emil Abderhalden. New and enlarged edition. (Pp. 480; illustrated. 34 francs.) Basle: Benno Schwabe and Co. 1946.

This well-produced handbook, with its companion volume *Lehrbuch der Physiologischen Chemie*, is intended to give without excessive detail an account of the functioning of the various organs of the body and of their relationships to one another in the normal circumstances of life. An English reader may find the German rather difficult—perhaps because it is too good—and the absence of side headings does not allow easy perusal; but this steam-roller effect is common in books in German. What is recorded is up to date.

The transference to another volume of those parts of the subject which have a chemical aspect or interest makes the book appear unbalanced—19 chapters out of 33 being devoted to special-sense physiology and the nervous system, while there are no chapters on heat regulation, diet, reproduction, or the endocrine system. The author mentions the last incidentally in connexion with the systems that he describes more fully—namely, digestion, circulation, respiration, and urinary secretion. We may perhaps concede that biochemistry is the science that fully treats of such subjects as diet and general and intermediary metabolism, but we would not have thought that a general textbook of physiology could omit them altogether. The methods and viewpoints of the chemist and physicist are essential for the solution of the problems of physiology, but these problems and their solutions remain within the framework of general biology. If the transference of much of the subject matter of physiology into the realm of biochemistry is before long to be followed by the removal into the realm of biophysics of all the remaining matter capable of exact and quantitative treatment, then indeed physiology, like the Cheshire Cat, will leave behind nothing but a smile.

C. LOVATT EVANS.

### MENTAL CONFLICT

*Our Inner Conflicts. A Constructive Theory of Neurosis.* By Karen Horney, M.D. (Pp. 250. 10s. 6d.) London: Kegan Paul, Trench, Trubner and Co. 1946.

The author does not write of different mental diseases in this book but discusses only the type of conflict which underlies any or all of the functional mental disorders. She regards this as a split in the total personality, which may be manifest in the sexual, social, or spiritual life of the individual. She considers that some of the leading medical psychologists may have interpreted the phenomena of psychopathology too narrowly. She believes that the conflicts of the neurotic are fundamentally no different from those of the normal person, but that the former is less able to resolve them; they therefore become more deeply unconscious and the two alternatives more incompatible. The author sees the basic conflict as between two attitudes towards people. A man may incline to be friendly towards people, in which case he will appear complacent and amiable, or he may incline to be hostile, when he will appear aggressive. In either case the repressed inclination will tend to break through, and only analysis will bring the conflict to the surface and resolve it. The conflict may be partially avoided by withdrawal from people; the patient will then appear indifferent. Dissatisfied with his real self, the neurotic often formulates an idealized image of himself to which he can never attain—a source of further dissatisfaction and conflict. The author also describes other mechanisms such as the neurotic's rejection of his own characteristics on to others, "god alightness," elusiveness, cynicism, and so on. She then considers the consequences of conflict such as fears, impoverishment of the personality, hopelessness and depression, aggression and sadistic trends, which, when the subject is subjected to them, may appear in the guise of their opposites. Finally the author refers to the difficulties of resolving these conflicts. She believes that prolonged deep analysis is necessary, though the process may be somewhat shortened if the

therapist understands the nature of the basic conflict and how the patient reacts to it. Superficial and brief analyses may benefit milder cases, but they do not get to the root of the trouble. Case histories clarify without unduly lengthening this unusual study of conflict. Psychotherapists will find it worth studying.

R. G. GORDON.

### RHEOCARDIOGRAPHY

*R.K.G. Rheocardiography. A Method of Circulation's Investigation and Diagnosis in Circular Motion.* By W. Holzer, K. Polzer, and A. Marko. Authorized English translation by Mrs. Emma M. Kreidl, of Vienna. (Pp. 43; 44 illustrations. 7 Swiss francs.) Vienna: Wilhelm Maudrich.

In this book Holzer and his collaborators describe a new method of recording the variations of impedance, which are very small, caused by the beating heart, to alternating current of moderately high frequency. They claim that this method records instantaneous changes of volume of the heart and therefore gives an indication of its output and the speed and power of contraction of the heart muscle. Leaky or stenosed valves will therefore also cause alterations in the "R.K.G." The technique used is briefly as follows: The source of alternating current is a short-wave oscillator, to which is coupled a secondary circuit that includes the subject; he is connected in circuit by the usual type of electrodes used in electrocardiography. The modulated high frequency wave is then rectified, the H.F. component filtered off, and the slow wave remaining amplified for examination by means of ordinary electrocardiographic equipment. The circuits are carefully stabilized, since the subject's impedance alterations, and consequently the voltages of the modulations, are small; most of the elaborations in the circuit diagrams are for this reason. The authors show a number of rheocardiograms, both experimental and pathological, and by simultaneous recordings of E.C.G., heart sounds, and R.K.G. are able to identify some of the features of the last—though perhaps not very convincingly. Atzler (*Arbeitsphysiologie*, 1932, 5, 6S., 636; *Disch. med. Wschr.*, 1933, 59, 1347) placed the subject's chest between the plates of a condenser which formed part of the secondary circuit of a short-wave oscillator. Since the dielectric constants of air (the lungs) and water (the blood) are very different, this method, by similar modulation, gives an indication of the immediate heart volume. The resulting curves are the same in many respects as those in this book, but the technical difficulties are too great for the method to be of any practical clinical importance. It is, however, possible that rheocardiography may prove to be of use, though more exact basic experimental work is required.

Unfortunately the translation spoils for English readers an otherwise interesting though sketchy monograph. Errors of translation, spelling, and grammar abound, and many electrical terms are unrecognizable except to one familiar with them in both languages.

DOUGLAS ROBERTSON.

### EXPERIMENTAL CANCER INHIBITION

*Effect of a Carcinogenic Hydrocarbon on Manifest Malignant Tumors in Mice.* By S. Stamer. With a summary in Danish. Translated from the Danish by Hans Andersen, M.D. (Pp. 158; illustrated. 12s.) Copenhagen: Einar Munksgaard. London: Geoffrey Cumberlege (Oxford University Press).

This monograph records experiments designed to test the inhibitory action of carcinogenic hydrocarbons on the growth of tumours as reported by Haddow and others. Stamer tested the highly potent carcinogen 9:10-dimethyl-1:2-benzanthracene on transplanted carcinoma, sarcoma, and leukaemia in mice. The carcinogen was very toxic when administered by intraperitoneal injection. The mice lost weight and the growth of tumours was inhibited, though not more than by a comparable reduction in body-weight effected by underfeeding. Most previous investigators did not take into account the loss of weight caused by the carcinogens, and their conclusions must be accepted with reserve.

Large doses of carcinogen injected intravenously did not appear to harm the mice; when so administered the carcinogen had no substantial effect on the growth of transplanted carcinoma or sarcoma but caused complete regression of transplanted

leukaemia. Stamer concludes from his experiments that for the treatment of human cancer large intravenous doses of carcinogens would be required and that the least differentiated tumours should respond most favourably. The discussion on the danger of producing new tumours is inconclusive. This book will interest the cancer research worker rather than the general medical reader.

L. FOULDS.

### TRAUMATIC INJURY

*The Pathology of Traumatic Injury.* A General Review. By James V. Wilson, M.D., M.R.C.P. Foreword by Philip H. Mitebner, M.D., M.S., F.R.C.S. (Pp. 192; 61 illustrations (several in colour). 20s. plus 7d. postage.) Edinburgh: E. and S. Livingstone. 1946.

Clinicians and pathologists will be grateful to Major J. V. Wilson for having compiled this general review of the pathology of traumatic injury. His main object has been to record wartime progress and to define the many problems that still remain unsolved. He reviews a considerable amount of the research work on trauma published in isolated papers during the war. Much of this research is recorded in inaccessible Service and official documents, and when it becomes available another edition of the book will certainly include it. He discusses shock, burns, crush, and blast with commendable precision, as well as such conditions as arterial spasm and concussion.

The author wrote this book under the stress of war while abroad, and references were difficult to obtain; this accounts for the occasional omission of up-to-date information—a relatively minor failing that will be rectified in the next edition. The illustrations are excellent and the subject matter is well presented and easy to read.

GEOFFREY HADFIELD.

*Alfred Adler: Apostle of Freedom.* By Phyllis Bottome. (Pp. 280. 12s. 6d. London: Faber and Faber. 1946.) Enthusiasm often distorts judgment, and the reader of this book must be careful not to confuse an appreciation of a master by a passionately devoted pupil with a scientific appraisal. Phyllis Bottome writes well and holds the attention of the reader from cover to cover, but her words are entirely adulatory: the master can do no wrong. Adler was more a teacher than a psychiatrist and his work appeals more to educationists than to doctors. The author thoroughly dislikes the Freudians, who would have no relations with Adler after his secession from the psycho-analytical school, and assures us that the latter was far the greater psychologist. It is too early to decide which of the eminent twentieth-century medical psychologists has the greater claim to fame; but it is, to say the least of it, uncertain that Adler will head the list. Again, Adler's advocacy of neighbourliness and the promotion of others' happiness is of course important and entirely admirable, but it might be thought from this book that it was an original idea; yet have we not heard of it, for example, in the Gospels, the books of Moses, and even in the ancient Egyptian Book of the Dead?

The second edition of *Local Anaesthesia: Brachial Plexus*, by R. R. Macintosh and W. W. Mushin (Oxford: Blackwell; 10s. 6d.), could more accurately be described as a reprint, since the only discernible difference from the original printing is the addition of a single paragraph on p. 10. The abundance of illustrations (many in colour), which are largely self-explanatory, makes unnecessary any account of tedious details of technique. Our only serious criticism is of terminology. The authors in their preface show clearly why the term "local analgesia" is more accurate than "local anaesthesia" but fail to carry this into practice in the body of the book, for the words are used as if they were interchangeable. It seems a pity that the opportunity to straighten out the terminology has been missed in this excellent monograph from the Nuffield School of Anaesthesia.

*The Medical Annual, 1946*, the sixty-fourth of its kind, faithfully reflects the advances recorded in every department of medicine. The emphasis is still on wartime experience, and references to D.D.T., atabrin, and penicillin are numerous. The alphabetical arrangement of the sections and the excellent index make it easy for the reader to refer to whatever subject is of immediate interest. "Books of the Year" lists English and American medical works and provides an easy guide for the postgraduate student. The editors, Sir Henry Tidy and Mr. A. Rendle Short, and their many contributors are to be congratulated on maintaining the high standard expected from this annual. The publishers are John Wright and Sons, Ltd., and the price is 25s.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Gas and Air Analgesia.* By R. J. Minnitt, M.D., D.A. 3rd ed. (Pp. 80. 5s.) London: Baillière, Tindall and Cox. 1947.

A practical handbook for the midwife and medical practitioner includes the latest regulations of the Central Midwives Board.

*Quantitative Clinical Chemistry Interpretations.* Vol. 1. By John P. Peters, M.D., M.A., and Donald D. Van Slyke, Ph.D. Sc.D. 2nd ed. (Pp. 1,041. 38s. 6d.) London: Baillière, Tindall and Cox. 1946.

Discusses energy exchanges and the chemistry and metabolism of carbohydrates, lipids, and proteins.

*The Diagnosis and Treatment of Bronchial Asthma.* By Leslie N. Gay, Ph.B., M.D. (Pp. 334. 27s. 6d.) London: Baillière, Tindall and Cox. 1946.

Intended for the student and medical practitioner; with reference and many illustrations.

*Modern Methods of Feeding in Infancy and Childhood.* By Donald Paterson, M.D., F.R.C.P., and J. Forest Smith, F.R.C.P. 9th ed. (Pp. 184. 8s. 6d.) London: Constable and Co. 1946.

Includes revised diet sheets for evaporated milk and recent information on the diet in coeliac disease.

*Medicine in the Changing Order.* Report of the New York Academy of Medicine Committee on Medicine and the Changing Order. (Pp. 240. 11s. 6d.) New York: The Commonwealth Fund (London: Geoffrey Cumberlege). 1947.

Reviews medical care in city and country, in public health and in the hospital, and suggests remedies for present inadequacies.

*Osler's Principles and Practice of Medicine.* By Henry A. Christian, A.M., M.D., F.A.C.P. 16th ed. (Pp. 1,539. \$10.) New York and London: D. Appleton-Century Company. 1947.

Changes in this edition include accounts of the sulphonamides and antibiotics, the regrouping of certain infectious diseases and a brief history of the edition of the textbook.

*Transactions of the American Ophthalmological Society.* Vol. XLIV. (Pp. 554. No price.) Philadelphia: American Ophthalmological Society. 1946.

Includes papers on cataract, the treatment of corneal wound healing, and ulceration, diagnosis of early glaucoma, and a number of experimental studies.

*Digest of British Social Insurance.* By T. S. Newman. (Pp. 322. 10s. 6d.) London: Stone and Cox. 1947.

An exposition for the layman of the Acts relating to National Insurance, Industrial Injuries, and Family Allowances, with index.

*Les Processus de Guérison des Cavernes Pulmonaires Tuberculeuses.* By Jean Tricore. (Pp. 174. No price.) Paris: G. Doin et Cie. 1947.

A monograph on tuberculous cavities in the lung and their treatment.

*Pédagogie du Nourrisson et du Premier Age.* By A. Thooris. (Pp. 184. No price.) Paris: G. Doin et Cie. 1947.

A practical account of the care of the infant; intended primarily for the layman.

*Maladies des Nourrissons et des Enfants.* By Germain Blechmann. 5th ed. (Pp. 758. No price.) Paris: G. Doin et Cie. 1947.

A textbook of children's diseases for the medical practitioner.

*L'Acetilcolina nelle Sindromi Schizofreniche.* By A. M. Fiamberti. (Pp. 454. No price.) Florence: Ditta Editrice Luigi Niccolai. 1946.

A monograph on acetylcholine deficiency in schizophrenia and its use in treatment.

*La Streptomycine: Etude Expérimentale et Thérapeutique.* By Alphonse Abaza. (Pp. 94. No price.) Paris: G. Doin et Cie. 1947.

Experimental investigation into streptomycin, its pharmacology and therapeutic applications.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 26 1947

## POLIOMYELITIS

The notifications of poliomyelitis in England and Wales rose in mid-June this year, which is earlier than their usual rise in late July. For the week ending July 5, 79 cases were notified; as we pointed out in "Epidemiological Notes," this represented a level which has seldom been exceeded since the disease was made notifiable in 1912. For the week ending July 12 the notifications numbered 110. The cases have been widely spread over the country, and, as is usual, it has seldom been possible to trace a connexion between them. In some patients a marked meningeal reaction at the onset and a prolonged pre-paralytic stage have led to a diagnosis of meningitis or meningo-encephalitis: this is perhaps reflected in the increase of notifications of meningitis. Bulbar and respiratory paralyses have been frequent. It is expected that many more cases will occur, and it may be useful to review briefly some points in our knowledge of the disease. We would draw attention to a memorandum from the Ministry of Health which appears at page 141.

The diagnosis has to be made on clinical grounds because there is no routine laboratory test for the presence of the virus. Suspicion is aroused when stiffness of neck or spine occurs during an acute infection with moderate fever in a child or young adult or occasionally an older person. Drowsiness alternating with irritability, hyperaesthesia, and exaggerated muscular reflexes may be present. Later, in a frank case there is diminution of some reflexes and weakness of some muscle group. Examination of cerebrospinal fluid will not give results specific for poliomyelitis, but it will help to differentiate meningococcal meningitis. Any of the symptoms mentioned may be absent, and it should be realized that infection with the virus of poliomyelitis may produce only a minor illness that cannot with certainty be diagnosed as poliomyelitis.

In dealing with a suspicious case it is advisable to isolate the patient because infectivity is probably greatest during the pre-paralytic stage. It is also wise to insist on rest in bed, since strenuous exercise has appeared to induce severe paralysis in some cases. There is no specific treatment: neither drugs, antibiotics, convalescent serum, nor any other treatment has been proved to decrease the incidence of paralysis or to limit its spread. When respiratory paralysis develops, as it may do quite suddenly, the use of an artificial respirator may be a matter of urgency. Other paralyses should be dealt with by appropriate splinting<sup>1 2</sup> under the supervision of an orthopaedic sur-

geon. Isolation of cases is advised for three weeks from the date of onset.

Attempts to control the spread of infection must be based on the knowledge derived from many field and laboratory investigations that when cases of poliomyelitis occur the virus is already widespread in the community. There is, in fact, a carrier epidemic with many symptomless infections, some cases of minor illness, and a few frank cases. Infection is spread usually from person to person and chiefly by carriers and children with minor illnesses. The virus is present in the throat of patients during the acute stage and during the incubation period, and is expelled from the mouth by blowing or spitting.<sup>3</sup> The virus is also present in the faeces during the acute stage and has been isolated from them in one instance nineteen days before the onset and in some many weeks after it. The virus enters the body by the pharynx or intestine, rarely if ever by the olfactory nerves. The incubation period is from 7 to 14 days or longer. The uncommon second case in a family usually occurs within a few days of the first.

U.S.A. studies<sup>4 5</sup> in the neighbourhood of cases have shown that the virus can be isolated more frequently from the family contacts of a patient than from persons in less intimate contact, and that it can be found, though still less frequently, in persons with no known contact. Virus has been isolated more frequently from children than from adults. There is thus some justification for excluding from school for a fortnight any children who are home contacts and for imposing quarantine on adult home contacts if they are food handlers or engaged in an occupation which brings them into touch with children. However, the value of quarantine in arresting the spread of poliomyelitis, as of other endemic infectious disease, is far less than the public usually thinks it is. It would be foolish to attempt to impose it so rigorously as to interfere with the occupations of adults and the activities of the community. There are arguments for abandoning it altogether, as has been done in some States of the U.S.A.

Closure of day schools is not advisable unless there is clear evidence of spread in a school, and even then it may be better to keep the children under supervision than to give them increased opportunities for closer contacts outside school. It is probably worth while to search for children with minor illness in school or absent from it and to isolate them for a fortnight. The procedure to be followed in a residential school on the occurrence of a case has recently been considered by a committee of medical men at the request of the Medical Officers of Schools Association. Their report<sup>6</sup> states that the known epidemiological facts do not allow of a dogmatic ruling about school dispersal, and that dispersal should be advised only after careful consideration of the circumstances and consultation with the local medical officer of health. Where poliomyelitis is prevalent, tonsillectomies should if possible be postponed, because the operation may precipitate a bulbar paralysis.

<sup>2</sup> Pearson, H. E., *et al. Amer. J. Hyg.*, 1945, 41, 155.

<sup>3</sup> Howe, H. A., and Bodian, D., *ibid.*, 1947, 45, 219.

<sup>4</sup> Report, *Lancet*, 1946, 1, 972.

<sup>5</sup> Seddon, H. J., Hawes, E. I. B., Raffray, J. R., *Lancet*, 1946, 2, 207.

<sup>6</sup> Macnamara, J., *Med. J. Austral.*, 1946, 2, 577.

Experiments have shown that flies may spread the virus by faecal contamination of food, and food ought of course to be protected from flies; but there is as yet no epidemiological evidence to justify an anti-fly campaign as a major item in a programme for the control of poliomyelitis. No vaccine is available, and there is no convincing evidence of the value of immune serum in prophylaxis; there is in fact some evidence<sup>7</sup> that serum antibodies do not confer immunity to paralysis.

A state of panic is rather easily produced by Press publicity, and it is to be hoped that the daily papers in this country will not draw undue attention to the present outbreak. In any year the cases and deaths due to poliomyelitis will be far fewer than the injuries and deaths caused by road accidents. The natural anxiety of parents might be allayed to some extent if it were more generally known that attack rates in large populations during the most severe epidemics have been only 2 or 3 per 1,000 and that second cases in families are uncommon. It should also be emphasized that the ultimate prognosis is not so bad as is popularly imagined. In a series of 296 cases in Baltimore<sup>8</sup> 50% recovered completely and 29% regained practically normal movement. There was marked paralysis in 18%, and 3% died. Similar results were recorded<sup>1</sup> in the Mauritius epidemic.

### STREPTOMYCIN IN TUBERCULOSIS

A number of speakers at the recent Commonwealth and Empire Health and Tuberculosis Conference in London gave the medical world at large some idea of what at this stage may be expected from streptomycin in the treatment of tuberculosis. Dr. H. S. Willis, Superintendent of the W. H. Maybury Sanatorium, Michigan, said that six or more laboratories were now concentrating on research into streptomycin, and that in the U.S.A. they already had records of 1,000 patients who had completed a course of streptomycin—the average course lasting from 90–120 days.

According to Dr. H. C. Hinshaw, of the Mayo Clinic, something like 500 kg. of streptomycin are being produced commercially each month. The American workers stressed the fact that in such a serious disease as tuberculosis a co-ordinated study was essential. While they had enough evidence to show that the use of streptomycin was a real advance in the treatment of tuberculosis, it was emphasized that only a small proportion of tuberculous cases were at present amenable to this treatment, and that the drug by no means replaced other current methods of caring for the tuberculous.

Streptomycin is looked upon as being an essential in the treatment of miliary tuberculosis, tuberculous meningitis, acute pulmonary tuberculosis, and certain other pulmonary lesions. Dr. P. M. D'Arcy Hart, a member of the Scientific Staff of the Medical Research Council, said that at the end of 1946 the M.R.C. had received from the U.S.A. about 50 kg. of streptomycin, sufficient to treat between 150 and

200 cases. The Report of the M.R.C. on streptomycin is awaited, but its main conclusion may be anticipated from Dr. Hart's statement that streptomycin benefits at least a small proportion of cases of miliary tuberculosis and tuberculous meningitis, and that the results were sufficiently promising to justify considering a wider use of the drug in these two conditions. He added, however, that the long-term results of treatment were still in doubt.

These observations are similar to those summarized in a report of the Committee of the American Trudeau Society which has just come to hand. This Committee and its Subcommittee on Streptomycin Therapy, under the chairmanship of Dr. H. C. Hinshaw, have carried out a series of trials with streptomycin during the past year and have also had the opportunity of reviewing results of trials conducted by the U.S. Veterans' Administration, the U.S. Army, and the U.S. Navy. They have also reviewed results of work previously undertaken at Cornell University, Mineral Springs Sanatorium, and the Mayo Clinic. The Committee considers that cases of tuberculous meningitis should receive intensive parenteral and intrathecal streptomycin therapy. It is pointed out that, though clinical remissions are frequently brought about by such treatment, subsequent relapse is likely to occur—this underlines Dr. D'Arcy Hart's cautious observation. The Committee also observes that "residual neurologic disorders are frequently noted." In view of the importance of prompt treatment the Committee states that this must often be instituted before bacteriological diagnosis is made. The Committee also recommends streptomycin for acute haematogenous miliary tuberculosis, tuberculous laryngitis, ulcerating tuberculous lesions of the oropharynx, and for progressive tracheobronchial tuberculous ulcers. It is not clear yet whether in this last condition results are superior when aerosol is combined with parenteral administration.

Streptomycin appears to be highly effective in the treatment of tuberculous sinuses of the skin. Although it is recommended that tuberculous pneumonia should be treated with streptomycin, it is not recommended for all types of pulmonary tuberculosis. Streptomycin is not indicated for chronic fibroid or fibrocaceous pulmonary tuberculosis, for acute destructive and apparently terminating types, or for early cases with a favourable prognosis; but encouraging results have been reported in the treatment of recent but extensive and progressing lesions. Streptomycin, it should be added, is apparently ineffective in the treatment of chronic tuberculous empyema. It is stressed that tuberculosis with a favourable prognosis should not be treated with streptomycin until more is known about toxicity and the appearance of drug-resistant strains; the latter seem to be one of the gravest drawbacks to streptomycin therapy. Drug resistant strains of *Mycobacterium tuberculosis* undoubtedly appear. This may be either because a normal bacterial population contains certain bacteria which are naturally resistant to streptomycin and flourish because the more sensitive organisms are killed off, or because a specific resistance to the drug is acquired, selection then coming into play. If the latter suggestion were proved it would seem, incidentally, to offer support to the Lamarckian theory of evolution. In a paper read at the

<sup>7</sup> Burnet, F. M., and Jackson, A. V., *Austral. J. exp. Biol. med. Sci.*, 1939, 17, 261.

<sup>8</sup> *Facts and Figures about Infantile Paralysis*, National Foundation Infantile Paralysis, New York, 1946.

Atlantic City Centenary Meeting of the American Medical Association, Drs. H. J. Corper and Maurice Cohn said that in experimental work on tuberculosis in guinea-pigs they found that prolonged treatment with streptomycin, while it retarded the disease, did not prevent the death of animals from tuberculosis, and that positive cultures could be obtained from the organs of animals treated for as long as 181 days. "In no treatment test in animals," they observed, "have we definitely been able to prevent a lethal outcome from tuberculosis by the use of streptomycin, although we have been able to delay such issue." This observation shows how necessary it is to be extremely careful in assessing the results of treatment. But Baggenstoss, Feldman, and Hinshaw,<sup>1</sup> describing five fatal cases of miliary tuberculosis treated with streptomycin, provide post-mortem evidence "of an inhibitory action exerted by streptomycin on human miliary tuberculosis and tuberculous meningitis." They demonstrated regression and healing in the miliary tubercles of the lungs, liver, and spleen—and by healing they meant the occurrence of fibrosis, hyalinization, and the absence of caseation: tubercle bacilli could, however, be demonstrated in the lesions. They stressed two important factors—namely, the size or mass of the lesion at the time of treatment, and the concentration of streptomycin in fluids and tissues. One striking fact was the presence of a significant concentration of streptomycin in the cerebrospinal fluid in contrast to its complete absence from the brain. The drug was given in these cases at 3-hourly intervals with a daily dosage ranging in the five cases between 1 and 10 g. Some workers in the U.S.A. at the moment seem to be obtaining satisfactory results with a daily dose of 1 g.

Much has been written about the toxic effects of streptomycin, but U.S.A. workers believe the greatest drawback to the use of the drug is the appearance of drug-resistant strains of the tubercle bacillus. Four types of toxic reaction have been observed: (1) the so-called histamine reaction characterized by flushing, headache, and an abrupt fall in blood pressure; (2) anaphylactic reactions; (3) disturbances of vestibular function and occasional deafness; (4) irritation of the kidney. This question of toxicity is the subject of a recent article by Farrington, Hull-Smith, Bunn, and McDermott<sup>2</sup> in an investigation conducted under the direction of the National Research Council Committee on Chemotherapeutics and Other Agents, under the chairmanship of Dr. Chester S. Keefer. It is not certain whether the toxic effects are due to streptomycin itself or to other substances present in the impure product. These observers believe that the so-called histamine reaction is the effect of the latter. In experiments with "chemically pure" streptomycin Molitor and his colleagues<sup>3</sup> found that daily doses of 25 mg. per kg. of body weight produced a fatty change in the liver and occasionally also in the kidney—changes which apparently were reversible. Evidence of labyrinthine or cerebellar disturbance was also noted. Farrington and his colleagues<sup>2</sup> have investigated the toxic effects in a group of human subjects given a four-month course of treatment

with highly purified streptomycin sulphate, a product "at least 95% pure." Sixteen patients received 3 g. of the drug daily for about 120 days, given at 3-hourly intervals in doses of 0.375 g. Three hours after injection the average concentration of streptomycin in the blood was between 10 and 20 micrograms per ml. of serum. In only two of the sixteen patients was it necessary to interrupt treatment because of toxic effects, in both cases anaphylactic—maculopapular rash, rise of temperature, nausea and vomiting, hypotension, and eosinophilia, and in one case an acute synovitis of the interphalangeal joints of the extremities. Apart from these obvious manifestations of anaphylaxis, Farrington and his colleagues observed eosinophilia in 14 of their 16 cases at one time or another during the 120 days of treatment. They regard this as a disquieting phenomenon "in view of the work of Rich and others<sup>4</sup> on the possible association of sensitivity to the drug with the development of diffuse vascular disease." Casts appeared in the urine of 14 of the patients and were related to the acidity of the urine. If the urine was kept neutral or slightly alkaline casts could be demonstrated in only one of these patients. In 14 of the 16 patients tests showed that renal function remained within normal limits throughout the period of treatment. Post-mortem observations on three patients who had received streptomycin up to 154 days and who had had numerous casts in the urine showed no renal abnormality. Deafness as a complication is a matter of excessive dosage and can be avoided.

Disturbed vestibular function is the commonest and most marked toxic effect and appeared in all 16 patients, usually between the 17th and 25th day of treatment. In 4 fatal cases of meningitis treated with streptomycin, Stevenson and his colleagues<sup>5</sup> found liquefactive necrosis in the ventral cochlear nuclei, and in two of them similar changes in the inferior vestibular nucleus; during treatment these patients had become deaf. In 14 of the 16 patients described by Farrington and his colleagues no tinnitus or impairment of hearing was observed, nor any other form of neurological abnormality. As to other toxic effects, leucopenia without granulocytopenia was observed in 2 of Farrington's cases. Repeated tests for liver function showed no evidence of damage. Although Farrington and his colleagues still consider that some of the toxic effects may be caused by residual impurities in the streptomycin preparation, they consider it is the streptomycin itself which irritates the kidney and causes the disturbance of vestibular function, brought about, in their opinion, by central action. Their general conclusion is as follows: "It is evident that highly purified streptomycin is a chemotherapeutic agent of low toxicity, since it was possible to administer moderately large doses of the drug for such a long period to persons who were seriously ill." The grave disabilities suffered by many patients temporarily recovering from tuberculous meningitis are, it would seem, the after effects of the meningitis rather than the after effects of the drug. Patients with disturbed vestibular function seem to be able to compensate for the disability when streptomycin therapy is discontinued, and in the view of U.S.A. observers the disability is slight compared with

<sup>1</sup> *Amer. Rev. Tuberc.*, 1947, 55, 54.  
<sup>2</sup> *J. Amer. med. Ass.*, 1947, 134, 679.

<sup>4</sup> *J. Clin. Invest.*, 1942, 21, 123.

<sup>5</sup> Observations which will be recorded in *Proc. Soc. exp. Biol.*, N.Y.

the disability of a severe illness. It should be added that repeated intrathecal administration of 0.1 g. of streptomycin is well tolerated.

Apart from the toxic effects of streptomycin there is another peculiar complication that has worried many thoughtful people in this country during the past few months, and that is the intermittent appeals sent out over the air from the B.B.C. for supplies to individual patients. This disquieting innovation in conducting medical treatment is, we believe, partly the result of the secrecy that has prevailed—a secrecy that was lifted when we were able to publish in the *Journal* of June 7 the names of those centres where treatment is being conducted on a very small national allocation of the drug. It seemed pertinent to inquire what were the results of the B.B.C. broadcasts, and this was done by the Public Relations Department of the British Medical Association. These are the results: Between Nov. 19, 1946, and April 17, 1947, the B.B.C. broadcast 21 appeals at the instance of hospital authorities. Twenty-one hospitals were asked for results of the appeal. Of the 18 who replied 15 stated that no streptomycin had been received as a result of the appeals. One hospital received 150,000 units, one received 3 g., and one received 5 g. When it is recalled that each of the patients studied by Farrington and his colleagues received 3-g. doses of streptomycin daily for approximately 120 days—a total dosage of 360 g. each—further comment hardly seems necessary. The response to the appeal produced totally inadequate supplies of the drug and can have done little but harm in that the appeal must have raised false hopes in the minds of the sufferers or their relatives. Streptomycin is still in very short supply. There is still need for prolonged investigations before the position of this drug in the treatment of tuberculosis can be accurately assessed, and there is still need for a far greater allocation of the drug from America until our own manufacturers are able to produce it in adequate quantities. Great Britain still seems to be getting less streptomycin than, for example, France. While we may sympathize with the B.B.C.'s desire to aid those who ask for an appeal to be made, we cannot but believe that the use of the radio for this purpose is improper.

### BOTULISM

The report of a recent inquest has again drawn attention to the rare form of food poisoning caused by the exotoxin of *Clostridium botulinum*. The best-known outbreak of this disease in Great Britain is that at Loch Maree in 1922, due to contamination of wild duck paste, but since then less dramatic episodes have occurred from time to time. An outbreak in Hampstead in 1935 due to infected "nut meat brawn" was commented on in a leading article in this *Journal*.<sup>1</sup> The usual sequence of events is that some article of food contaminated with *Cl. botulinum* is preserved in either tin or bottle without being adequately heated. The spores are highly resistant to heat, being able to survive for some three hours at 212° F. (100° C.) and 36 minutes at 230° F. (110° C.). The anaerobic conditions in the tin or bottle enable the organism to proliferate and produce toxin. If the contents are then eaten

either uncooked or inadequately cooked the toxin causes botulism. The toxin, unlike the spores of the organism, is relatively easily destroyed by heat—for example, usually by boiling for five minutes. When the victims have taken a large dose of toxin, as at Loch Maree, symptoms will begin to appear in some in about fifteen hours.

The symptoms are vomiting, obstinate constipation, and cranial nerve palsies. Diplopia, ptosis, and difficulty in speech, swallowing, and breathing are particularly prominent. There is no loss of consciousness. In fatal cases these symptoms become worse, but consciousness generally remains to the end. Even at Loch Maree, where all eight patients died within a week, there was great variability in the rapidity of onset of symptoms; in some the onset was insidious. In cases in which the dose of toxin has presumably been small the clinical picture may be very puzzling, and the relationship of the symptoms to food poisoning may be obscured. There is usually a history of vomiting associated with constipation. The characteristic cranial nerve palsies may come on very gradually—in days rather than hours—but when they do appear they are apt to persist. Disturbances of vision and diplopia are common symptoms. Fixed dilated pupils are a common physical sign.

The mild case is probably less common than the severe because the concentration of toxin in the food is generally considerable, but it is probable that under conditions relatively unfavourable to the organism small amounts of toxin may be produced and mild cases may result. It is likely, for example, that in a large mass of foodstuff which contains spores toxin may be produced in the centre even when the surface of the foodstuff is exposed to the air. The long list of foodstuffs given by Meyer<sup>2</sup> as having caused botulism in the U.S.A. shows that strictly anaerobic conditions in tin or bottle are not essential. As the natural habitat of the organism is the soil, the vehicle has commonly been inadequately heated home-canned vegetables, but unsealed foods may exceptionally be to blame. Quite moderate cooking of the foodstuff before eating is sufficient to destroy the toxin.

### FOOD POISONING

Food poisoning may be defined as any illness that results from the ingestion of food. This includes a wide variety of different substances, such as poisonous plants, fungi, metals, organic and inorganic chemicals, and bacteria and their products which have become incorporated in the food. In addition it may be correct to include the individual idiosyncrasies of certain persons in their reaction to, for example, shell-fish or strawberries, the eating of which may be followed by an attack of urticaria. There is a widespread tendency for the public to blame the quality of the food as being the cause of illness, instead of realizing that the food is in most cases contaminated by those who handle it and by flies and vermin that are allowed to gain access to it. There is no question that the number of outbreaks appear to be increasing, but it is difficult to say how much this is due to an actual increase and how much to the greater interest taken in food at the present time and to the fact that food poisoning is now notifiable. Communal feeding cuts both ways; thus, if an outbreak occurs in a large canteen attention is drawn to the numbers affected, whereas if the same number fed at home it would be impossible to assess how many would have been affected by a gastric enteritis that passed off rapidly and was never reported.

<sup>1</sup> *British Medical Journal*, 1936, 1, 64.

<sup>2</sup> Meyer, K. F., *Amer. J. publ. Hlth.*, 1931, 21, 762.

The great majority of outbreaks are due to the enterotoxin produced by the *Staphylococcus aureus* (coagulase positive), which is ubiquitous and is introduced into the food by those who handle it. Contamination may come from the hands, which may be infected from any septic condition the subject has on his person, and also from the nose, especially if a catarrhal condition is present. In canteens and elsewhere much food is prepared the day before it is eaten and reheated the next day before the meal is served. During this time the enterotoxin is formed; it is not destroyed by heat except at a temperature above boiling point. The difficulty therefore of implicating the infected food when the staphylococci have been killed can be appreciated.

The salmonella is responsible for many outbreaks, and *Salm. typhi-murium* is the most common in Britain. The clinical symptoms when infection is due to food contaminated by this organism occur much later after consumption than when the staphylococcal enterotoxin is the contaminant—12 to 24 hours in contrast to 3 to 4 hours. In severe cases the symptoms produced by the *Salm. typhi-murium* are indistinguishable from those of the enteric group. The effects are very variable, since many healthy carriers are found, others have only a mild gastro-enteritis, and every grade of illness up to a fatal issue may occur. Every year the consumption of duck eggs gives rise to a varying number of infections. They should therefore be boiled for 8 minutes; in Germany a notice to this effect must be displayed in shops which sell them. Dried egg has been incriminated in many cases, but after an extensive research by the Medical Research Council they were able to state: "If dried egg is efficiently cooked immediately after reconstitution, the risk of salmonella infection therefrom does not arise."

To diminish food poisoning it is essential to insist on a high standard of cleanliness, the minimum amount of handling of the food, and that all who handle food must scrub their hands with soap and hot water before starting work; if they must dry their hands they should do so on a clean towel. This measure is especially important after using the lavatory. It has been said that much illness has been caused by consuming some person's excreta—nasal, oral, or intestinal.

### RADIO-ACTIVE PROGRESS

Previous assessments of the value of radio-phosphorus ( $P^{32}$ ) in the treatment of polycythemia vera<sup>1,2,3</sup> have necessarily been based on comparatively few cases, with only short periods of follow-up. In delivering the 24th Mackenzie Davidson Memorial Lecture of the British Institute of Radiology last week, Dr. John Lawrence, of the Crocker Radiation Laboratory, Berkeley, California, paid his audience the same compliment in proceeding beyond the published record that Prof. Robley Evans, of the Massachusetts Institute of Technology, had lately extended in describing, also in London, the latest results from the treatment of Graves's disease with radio-iodine.<sup>4</sup> Dr. Lawrence is a brother of Prof. E. O. Lawrence, the physicist, who designed and built the first cyclotron, and from 1934 onwards, as he stated, he has had access to radio-isotopes "in fairly large quantities." He brought with him the first analysis of 90 cases of polycythemia vera treated with  $P^{32}$ , and 20 further cases which had not been. His real controls were, however, a Mayo Clinic series of 163 cases, of which the survivors at the end of five years numbered 36.

This proportion is liable to revision, but at the moment is regarded as the best figure available. Of the 90 cases treated at Berkeley, the earliest goes back to 1939, and the number of deaths to date has been 13. Also, whereas the average age of those treated was 48 years, the average age of those who died was 66.6 years. More encouraging even than these overall figures was the analysis given of causes of death. These included four cases of cardiovascular disease (of which three were at ages between 70 and 80), 1 of acute pancreatitis, and 3 of carcinoma. None of these eight deaths was regarded as attributable, nor in particular was there any evidence in the three latter cases of induction of carcinoma. At the most, therefore, only five cases remained in which it appeared possible that the cause of death could reasonably be connected with either the polycythemia or the treatment given for it. As to four out of these five cases (3 leukaemia and 1 multiple myeloma) no useful opinion could be expressed. Finally, there was only one death in the whole series from thrombosis, which in most previous series has been a common sequel. Follow-up studies are being continued, but in relation to the severity of the disease radio-phosphorus therapy would appear to have already been justified.

For the future Dr. Lawrence raised some interesting and frankly speculative prospects by his preliminary account of the work which has been done on the administration of radio-active substances in colloidal form. There is here the possibility of selective absorption with the properties of the individual cell membrane as the determining factor. By a suitable choice of chemical form and particle size it is suggested that it may be possible to guide radio-active colloids to the spleen, lymph nodes, or bone marrow as might be required. Work on these lines will be further described at the International Congress of Physiology at Oxford during the present week.

As two examples of the tracer technique of direct and related interest to medicine, Dr. Lawrence instanced the use of radio-sodium and radio-gold for the study of the symptoms and treatment respectively of rheumatoid arthritis. The effect in the former case has been to confirm quantitatively the clinical picture of impaired circulation. Using a rabbit in one leg of which arthritis had been chemically induced it was demonstrated with radio-sodium ( $Na^{24}$ ) that the rate of blood flow in the affected leg was nearly twice as slow to the articular cortex, more than three times as slow to the synovia, and more than four times as slow to the tendons as in the other and normal leg. On the side of treatment, it has been similarly shown with the aid of radio-gold ( $Au^{199}$ ) that the distribution of colloidal gold is such as to lend plausibility at least to this form of therapy. The concentration in the synovia has proved to be rather more than ten times as great as in the muscles, so that absorption may fairly be claimed to be selective to that extent—although, as Dr. Lawrence was careful to point out, the presence of the gold in the desired locations provides no proof in itself of beneficial effect. Such evidence has the same kind of value as the use of x-ray analysis in the testing of chemical theories of protein structure. It can prove that any particular theory is wrong; but not necessarily, as Bernal lately pointed out, that it is right. "No chemist," he stated characteristically, "can to-day put forward a bogus theory and get away with it." Neither, as radio-isotopes become more widely available, will the medical research worker be able to postulate selective absorption which does not in fact take place. This is no mean contribution to have been initiated by a laboratory which, in Dr. Lawrence's words, was "founded and organized in the belief that the future of medicine will be increasingly tied up with chemistry and physics."

# CINERADIOGRAPHY IN ORTHOPAEDIC SURGERY

BY

LEON GILLIS, M.B.E., M.Ch.Orth., F.R.C.S.

Senior Surgeon, Queen Mary's (Roehampton) Hospital

In 1897 Dr. John MacIntyre produced a pseudo-cineradiographic record by taking a series of ordinary skiagrams of the frog's leg in different positions and arranging them in order to show the movements. These were afterwards transferred to a cinematographic film. Since then three distinct methods have been adopted: (1) The original synthetic method of MacIntyre. (2) The direct method, in which a band of film is exposed direct to x rays in a rapid series of exposures, as in ordinary radiography. (This method has been successfully developed in recent years by Van de Maele, of Brussels, and Barclay, of Oxford.) (3) The indirect method, where a motion picture record is made of the fluorescent screen image.

Russell Reynolds has worked on the indirect method since 1921; later he coined the word "cineradiography." To this pioneer must be given most of the credit for the development of this particular method into a true cinematographic recording. The indirect method is the only practical method available for study to-day.

Cineradiographic films can be studied indefinitely, and repeated examinations within reason are not detrimental to the health of the patient or examiner. The strips of film recording these examinations can be kept with the case notes and may accompany the case anywhere. Their value lies in a permanent record of movements which can be used for: (1) diagnosis; (2) comparison with former records to watch the effect of treatment or the progress of a pathological condition; (3) research (as in cases where it is impossible to visualize a whole physiological process or, for instance, the behaviour of a stump within an artificial-limb socket); and (4) teaching purposes. The immediate advantages of a record of what can be seen on the fluorescent screen are that the film will permit a leisurely and repeatable study of movement and that the action can be stopped at any stage for a closer scrutiny of any particular image which may excite interest.

## Normal and Abnormal Joint Movements

In 1905 Levy-Dorn showed a synthetic film of the movement of the knee and elbow obtained by placing in order a number

of exposures, taken in series, of various positions of the bones. In 1907 Köhler followed with another synthetic film. To-day we can study joints in the body and record their movements accurately, and so obtain a knowledge of the disposition of the elements of the joints in any particular phase of the cycle of their movement.

The physiologist and the anatomist benefit by this knowledge, and the orthopaedic surgeon who is in doubt as to what is actually happening in a joint can see, without the introduction of any contrast medium, any alteration in its mechanics—for example, abnormal movement consequent on a torn cartilage or ligament in a knee-joint.

It is possible to see whether a joint has been successfully arthrodesed. Recently an arthrodesis of a wrist was attempted by two well-known surgeons, but the wrist remained painful in spite of prolonged immobilization. A skiagram showed that there was apparently complete bony fixation. Clinically no movement could be detected, yet the patient complained of pain. A cineradiographic film revealed that movement was taking place. An exploratory operation showed that bony union had not in fact occurred.

Often it is difficult to tell radiographically and clinically whether a fracture is soundly united. In cases of doubt cineradiography may show that movement is still present. A large series of abnormal joint movements have been filmed, examined and compared with the normal. It is revealing to see the deviations from normal joint movement caused by abnormal posture, ligamentous injuries, subluxations, and fractures.

## Artificial Limbs

Even with the employment of the best artificial limbs there remain some cases in which the wearer of an appliance complains of pain in his stump. It is in such cases that cineradiography opens up a completely new field of investigation. The cause of the pain may be obvious. It may be due to ulceration to a bursitis, or to a septic sebaceous adenitis. On the other hand, there may be nothing to see, or even to feel, and the diagnosis may not be apparent. The painful stump may be relieved by leaving off the limb, in which case the limb is probably to blame. In order to be able to understand why the pain is either initiated or aggravated while the limb is being worn it is necessary to know the behaviour of an ideal stump in a well-fitting limb. Hitherto we have relied on experience and clinical judgment in the diagnosis and treatment of the causes of a painful stump.

Cineradiography opens up a new field in the diagnosis and treatment of this condition and provides us with a new

Table showing Cineradiographic Observations on Stumps with Artificial Limbs

Case No.	Amput. Level	View	Markers	Shape of Stump	Spur Form	Movements of Stump In Prosthesis				Result on Soft Tissues at Apex of Stump	Correspondence of Axis of Stump with Axis of Limb	Remarks
						Ant.-post.	Side to Side	Rotation	Piston Action			
Above-knee Amputations												
1160	Upper 1/3	A.-P.	+	Conical	-	Slight	Slight	-	-	-	+	No movement at all between limb and prosthesis
1162	Upper 1/4	A.-P.	+	Square	++	0	++	-	-	+	+	Very marked lateral movement. Ischial bearing
1178	Lower 1/3	A.-P.	+	"	++	+	+	-	++	-	+	A curious lateral-medial-lateral movement of stump in socket on weight-bearing. Very large medial spur. On slight A.-P. movement
Below-knee Amputations												
1164a	Upper 1/3	A.-P.	-	Conical	-	0	-	-	Marked	-	0	Bone-end very close to skin
1164b	Upper 1/3	Lat.	-	"	On fibula	+	0	-	++	-	0	Bone-end of tibia very close to skin. Stump became more pointed with weight-bearing; there is slight latero-medial movement of stump on weight-bearing and also antero-posterior movement
1164c	Upper 1/3	A.-P.	-	"	"	0	Slight	-	++	-	0	
1194	Upper 1/3	A.-P.	-	Tends to square	-	0	-	0	++	-	0	
1195	Above upper 1/3	Lat.	-	"	-	+	0	-	++	-	0	Bone-end well padded. Stump tends to square. Fibula about 2 in. (5 cm.) shorter than tibia, which is amputated above upper third level. A.-P. movement present on weight-bearing. Stump more conical in lateral than in A.-P. view. Film shows that when weight is applied correspondence of axis of prosthesis and joint is good at through flexion
1195a	Above upper 1/3	Lat. flexing knee	-	"	-	0	0	-	0	0	Good	
1150	Upper 1/3	A.-P.	+	0	-	0	-	0	+++	0	0	A little longitudinal movement on weight-bearing. Movement of bone very great and of soft tissue much less. Skin attached on the medial side. This is the most marked feature
1151	Upper 1/3	A.-P.	+	Square	-	+	Slight	0	+++	+++	0	

0 = Not observed. - = No movement. + = Movement. +++ = High degree of movement.

valuable method of investigation into the combined behaviour of the stump and prosthesis in any movement which the patient is able to make. I have recently been carrying out such examinations on both painless and painful stumps fitted with various types of artificial limbs. Study of such films shows that a mass of useful information may be obtained and that the interaction of stump and prosthesis is often unexpected and complicated.

In the usual method of investigation lead wires are fastened securely in various positions to the skin of the stump before the artificial limb is put on. When the films are projected the wires show clearly the degree of movement between the skin and the prosthesis, and indicate also the amount of stretching of the tissues which results from piston action. If the stump is painful the patient is provided with a "pain indicator" so arranged that by pressing a button at the moment when pain occurs an opaque pointer or a point of light appears beside the shadow of the limb on the fluorescent screen and is simultaneously photographed. In this way it is possible to determine the moment at which pain occurs and to see the movement of the stump within the prosthesis which produces it.

Much valuable information has already been obtained. As might be expected, the relative movement of stump and prosthesis varies considerably, depending on the length of the stump, the type of amputation, and the design of the artificial limb. In many cases piston action is a prominent feature, and in these it is instructive to compare the relative movement of the bone and the soft tissues in the stump. In some cases piston action is replaced or added to by antero-posterior, lateral, or rotary movement. In some types of socket with a short femoral stump the bone actually tends to rise out of the prosthesis when weight-bearing.

The table gives a few facts which I observed in a series of cases, and some of these seem paradoxical.

### Illustrative Cases

**Case 1164a.**—This case shows two outstanding features: (1) that the axis of the artificial limb and the axis of the stump correspond very poorly, and (2) that there is a great deal of piston action. The patient complained of much pain in his stump when walking. After realignment of the artificial limb the axis of the stump and that of the artificial limb were found to synchronize much better, the piston action was eliminated, and the patient said he was comfortable. It is noteworthy here that the piston action and the poor axial relation between the stump and the artificial limb coexisted.

**Case 1195a.**—This patient complained of a painful below-knee stump. There was no obvious neuroma to be felt. The stump was not tender. Cineradiography showed that there was good co-axial correspondence between the stump and the artificial limb. Piston action was practically absent. This indicated that the artificial limb was satisfactory and that the fault lay in the stump itself. The patient was subjected to an operation for division of the popliteal nerves. The artificial limb was not altered. He was discharged relieved.

### Comment

The above are two of the many cases that have been analysed and successfully treated along these lines.

**Points noted and studied include:** (1) The varying axes of stump and different prostheses. (2) The varying relations between the artificial joint and the natural joint in short below-knee and below-elbow amputations during movement. (3) The relation of the direction of painful and non-painful spurs to the movement of the stump in the prosthesis.

Active research is being continued both to obtain more data on the behaviour of a stump in an artificial limb and also to determine the most suitable type of stump and prosthesis in amputations at various levels. For this purpose not only are more examinations of existing prostheses required but other experimental types of artificial limbs with various stumps should be tried. The problem is not one which can be rapidly solved, as a certain time must elapse before effects become apparent.

### Summary

Cineradiography is shown to have great scope in research—for example, the behaviour of stumps within artificial limbs.

The application of cineradiography in the diagnosis and the control of treatment is discussed.

I should like to thank Sir Walter Haward, Director-General Medical Services, Ministry of Pensions, for permission to publish this article. To Dr. Russell J. Reynolds I am most grateful for the facilities he has made available. I also wish to thank the energetic team, comprising Drs. Seymour J. Reynolds, Hugh Hay, and Stewart Russell Reynolds, for their co-operation.

## ACUTE POLIOMYELITIS

### Memorandum by Medical Officers to the Ministry of Health

Notifications of poliomyelitis and polio-encephalitis for the week ending July 12, 1947, are 110 and 16 respectively. The highest weekly figure previously recorded since poliomyelitis became notifiable in 1912 was 82 in 1938. This peak was reached in the week ending Aug. 13, 1938. Having in mind the usual seasonal trend and the fact that a significant increase in notifications rarely appears until the end of July, we may expect the early start this year and the present high figures to be reasons for anticipating an unprecedented prevalence.

So far this year the notifications of polio-encephalitis have been higher than ever before. Bulbar and respiratory paralysis and meningeal reactions preceding paralysis appear to be more common than is usual in poliomyelitis.

### Clinical Appearance

Typically there are three phases in the illness recognizable as poliomyelitis. In many cases there is also an initial or prodromal illness followed by a distinct interval of five to seven days before more serious signs of disease appear. The chronology may be tabulated as follows.

		Usual Incubation Period from Date of Infection	Manifestations
Stage A	Prodromal illness	1-4 days	Fever, weakness, perhaps sore throat or diarrhoea, and occasionally pain in chest or limbs
Stage B	Anterior poliomyelitis: Phase 1 (onset)	7-18 days (up to 3 weeks)	Fever, flushed face, furrowed tongue, considerable headache, sometimes vomiting; drowsiness, irritability, and vague subjective phenomena; increasing stiff neck; sometimes exaggerated tendon reflexes
	Phase 2 (pre-paralytic or meningitic)	10-15 days	Sometimes marked intoxication and coma; pain on flexion of neck and spine; tenderness and hyperaesthesia; sometimes nystagmus
	Phase 3 (paralytic)	13-18 days (up to 35 days)	Hyperaesthesia and weakness of muscle groups going on to flaccid paralysis due to anterior horn cell lesions; diminution in tendon reflexes. There is a marked tendency for paralysis to improve after it has reached its height

The prominent symptoms in all phases of Stage B are referable to the C.N.S. They suggest a certain order of progression, which may be indicative of the progress of inflammation within the central nervous system. There may be intermissions in this progression, and one or both of the later phases may not develop.

An illness probably due to the same virus, in which the lower motor neurones escape and the signs and symptoms are predominantly those of meningeal and cerebral involvement, is notifiable as polio-encephalitis.

### Infectivity

The disease has been notified from many different centres throughout the country, and from some of these there has been evidence of radial or concentric spread. It is known that non-paralytic cases of the disease are able to transmit it to others; who may or may not develop paralysis. Laboratory investigations have amply confirmed this and have also demonstrated the presence of poliomyelitis virus in healthy contacts. Infectivity is, however, probably greatest during the phases preceding paralysis; in fact the clinical paralytic disease is essentially an infrequent incident occurring among a far larger number of cases aborting in Stage A or Phase 1 of Stage B. These are none the less infectious.

### Action by Practitioner

At this time poliomyelitis should be considered whenever a practitioner is called to see a febrile child (or even an adult) with indeterminate symptoms, particularly if there are other persons in the environment exhibiting the same symptoms or if there has been, within a period of two weeks, any other febrile illness—e.g., "flu," sore throat of unknown origin—in the patient or his contacts. The patient should be put to bed in a room by himself and examined at every visit until a diagnosis has been made. Careful search should be made for the early indications of invasion of the nervous system (e.g., neck rigidity). A good way of eliciting this is to ask the patient to kiss his knees while sitting up in bed. If within 24 to 36 hours the symptoms continue and no signs diagnostic of one or other of the common infections of childhood appear, the medical officer of health should be informed. There should be no hesitation in reporting a case to the medical officer of health if in the presence of the slightest suggestion of rigidity of the neck there have also been psychological disturbances such as fear, bad dreams, disturbance of sleep, drowsiness by day, restlessness by night, peevishness, etc. These disturbances not uncommonly precede the signs of meningeal invasion. Home isolation at onset and on suspicion is a most useful measure in the prevention of spread of the disease. Nose and throat discharges and excreta should be disinfected.

A patient who is suspected of poliomyelitis should be kept continuously in bed in a room by himself for not less than one week, having regard to the well-known tendency for the symptoms and fever to subside in two or three days' time and then to recur. Isolation of confirmed cases from other children should continue for three weeks. Contacts should be excluded from school for three weeks after isolation of the patient. Restrictions need not be placed on adult residents in an affected household provided they remain well.

It is notoriously difficult to judge the value of any treatment in poliomyelitis. There is no evidence that convalescent serum given in the pre-paralytic stage or after has any curative effect. Experience of prophylaxis with gargles and nasal sprays has been disappointing. There is, however, overwhelming evidence that a recent tonsillectomy increases the risk of a child's contracting poliomyelitis, particularly of the bulbar type. Prevalence of poliomyelitis in an area should therefore be an indication for the postponement of operations on the nose and throat whenever possible.

### Action by Medical Officer of Health

On receiving a notification or learning of suspected cases of poliomyelitis the medical officer of health should proceed on the following lines: (a) advise all practitioners in the area; (b) assist in securing suitable accommodation, including isolation, for the patient in hospital or otherwise; (c) investigate the associated circumstances, including a search for missed and abortive cases; (d) ensure that precautions are taken on the assumption that the disease is capable of transmission by mild abortive cases; (e) follow up all notified cases throughout the whole period of their illness to ensure that their treatment is suitable and continuous.

When multiple cases have occurred in a district all crowded assemblies should be discouraged, and so far as is possible all gatherings of young children and unnecessary travel avoided. Young children should not be allowed to enter any house where there is a case of undiagnosed illness. Contacts should avoid

physical strain. School closure is undesirable except under special circumstances.<sup>1</sup> This advice does not apply to day nurseries and nursery schools. So far as possible the normal groupings of the child population should be maintained and sick children removed promptly.

The medical officer of health should also advise his council, first, on what can be done to promote early diagnosis during the acute stage, and, secondly, on what arrangements can be made under the local orthopaedic scheme to send all children affected, whether the condition is slight or serious, to an institution equipped to give such special treatment as may be required to prevent avoidable muscular weakness or permanent deformity. In view of the common occurrence of cases of poliomyelitis below the age of 5 years, and bearing in mind the good results of effective treatment and the serious consequences of neglect, it is important that doctors should know of the facilities for orthopaedic treatment available through the maternity and child welfare and school health services. In the course of their routine visits health visitors may hear of suspicious early cases or of children with mild paralyses due to an undetected attack. If the local prevalence assumes epidemic proportions information should be circulated to the public regarding the care to be observed in the event of attack and the facilities for treatment available in the district.

In view of the fact that the virus is excreted in the faeces and has been found in flies the possibility of water-borne or other alimentary infection should be kept in mind, although reliable evidence of spread by these means is lacking.

### Laboratory Investigations

In addition to any routine chemical and cytological examinations of cerebrospinal fluid which may be carried out locally for diagnostic purposes there are certain examinations being done at the Central Public Health Laboratory which, although not of direct help in the diagnosis of individual cases, may throw some further light on the epidemiology of the disease. The specimens required for these investigations are: (i) About 5 ml. of serum from definite or suspected cases. Wherever possible two specimens should be sent from each case, one taken in the acute stage and one in the convalescent. (ii) Specimens of cerebrospinal fluid or of fresh post-mortem material from cases of doubtful diagnosis—i.e., those cases in which meningeal or encephalitic signs and symptoms predominate. Post-mortem specimens (brain or spinal cord) should be placed in equal parts of glycerin and normal saline. Both specimens and cerebrospinal fluid must be kept in a refrigerator, and arrangements will be made for collection if the Public Health Laboratory Service is notified.

Specimens should be sent to Dr. F. O. MacCallum, Virus Reference Laboratory, Central Public Health Laboratory, Colindale Avenue, London, N.W.9 (Telephone: Colindale 6041).

### RADIO-ISOTOPE SUPPLIES

Arrangements for the supply of radio-active materials for research were discussed at a conference held in Manchester by the Institute of Physics from July 10 to July 12.

Dr. J. D. Cockcroft, Director of the Ministry of Supply's Atomic Energy Research Establishment, stated that a small nuclear pile of some 50 kilowatts output should be working before the end of the year. This would be followed by a large pile of the order of 1,000 kilowatts output, and also by cyclotron production on a smaller scale of those radio-isotopes which could not be obtained from the piles. The general rule was that radio-isotopes which had masses greater than those of the corresponding stable isotopes of the same chemical element could be obtained from piles, while those of smaller mass had normally to be obtained from a cyclotron. The difference in output was about a thousand to one in favour of the pile method, but United States experience had shown that, with double-shift working, a cyclotron could be effectively operated for an average of 20 hours in every 24. He mentioned with approval the use of an alarm bell to arouse the

<sup>1</sup> *Lancet*, 1946, 1, 972.

night operator if the current represented by the bombarding beam fell by 10% below its proper value.

Estimates had also been prepared of the output which could be expected from a 1,000-kilowatt pile. By concentrating on radio-phosphorus ( $P^{32}$ , half-life 14 days) 40,000 curies of radioactive material could be made in a month. For radio-cobalt ( $Co^{60}$ , half-life 6.3 years) a year's working should yield 5,300 curies. This was the radio-isotope which had been chiefly favoured as a substitute for radium.<sup>1</sup> For radio-hydrogen ( $H^3$ , half-life 31 years), which should be of considerable value in biological and medical research, output during the same period should be 900 curies. These figures were for material irradiated in the central area of the pile. Some additional output could also be obtained in suitable cases by irradiation in the reflecting blocks, which were used to return as many as possible of the fission-producing neutrons to effective use in the pile. Finally, the fission products themselves would be used to provide the most intense source of mixed radiation which the Establishment would provide. From 10 grammes' weight an activity of 5,000 curies, with an effective half-life of about 100 days, could be expected.

All radio-isotopes listed for internal supply in the United States<sup>2</sup> would be produced at Harwell, and there would also be a "consumer demand" service. Laboratories wanting particular radio-isotopes not included on the list could write, stating their requirements, and if possible they would be supplied. In general the order of priority would be Harwell's own research requirements first, university laboratories second, and other users third. Allocations would be made by a committee, on which the Medical Research Council was represented, and it might be assumed therefore that the final criterion would be the value of the research which it was proposed to undertake rather than the formal status of the hospital or laboratory concerned.

A further point which emerged from Dr. Cockcroft's address was that, although small supplies of cyclotron-produced isotopes from United States sources had been made available to the Medical Research Council, the form of existing legislation in that country is such as to prevent the export of any radio-isotope made in a nuclear pile, although their properties have in most cases been freely published.<sup>3</sup>

### Distribution and Disposal

Dr. J. V. Dunworth (A.E.R.E.) referred to the production of "eight-days" radio-iodine ( $I^{131}$ ), which, as Prof. Robley Evans lately indicated,<sup>4</sup> has been adopted as the standard form of radio-iodine in the treatment of Graves's disease. He mentioned also that  $C^{14}$  was among the exceptional radio-isotopes which, although of lower mass than the corresponding stable isotopes, could none the less be prepared in a pile. It had a half-life of only 20 minutes, but on account of the greater energy released in its breakdown would be easier to work with than the more familiar form of radio-carbon ( $C^{14}$ ). The latter had a half-life of more than 6,000 years but, its radio-activity being comparatively feeble, was less easy to detect and to measure.

Mr. W. G. Marley (A.E.R.E.) gave some further information on distribution plans. Radio-isotopes prepared in the pile by irradiation of stable forms of the same chemical element, by a straightforward process of neutron absorption, would be distributed in the original aluminium "cans" in which they had been irradiated. Chemical separation, where necessary, would be undertaken centrally. This applied both to substances such as  $C^{14}$ , which involved transmutation from a different chemical element—nitrogen in the example quoted—and also to those radio-isotopes which were most conveniently obtained from the fission products built up in a pile during its normal operation. Distribution would in general be through the Amersham centre, but direct supply was not excluded in the case of short-lived radio-isotopes, for which speed of transport was essential.

Referring to safety precautions, Dr. Dunworth stated that one microgram of plutonium in a cat would suffice to cause at that point a sarcoma which was likely to be fatal. The

fouling of drains with radio-active material of any kind must be prohibited, and large quantities could be disposed of only by sinking in the ocean. Before distribution competence to handle would have to be established, including the making of routine measurements of contamination. Local committees of physicists, chemists, and medical practitioners might, he suggested, be established for this purpose.

### ANIMAL BENEFACTORS OF EXPERIMENTAL RESEARCH

The tables were turned on anti-vivisectionists by Prof. G. H. Wooldridge in his Stephen Paget Memorial Lecture to the Research Defence Society on June 17, when he described the benefits brought to animals as a result of experimental research. Dealing in the first place with anaesthetics, he pointed out that the vast majority of these agents, general and local, were either discovered or perfected as a result of such research, and that this had meant that hundreds of thousands of essential operations annually performed on animals were now carried out without any pain or suffering whatever. All veterinary surgeons as a routine measure resorted to anaesthetics on every possible occasion to prevent and relieve pain. Many suffering animals whose recovery was hopeless had been given the benefit of euthanasia by means of "nembutal."

The use of sulphonamides, again, had been established by experimental research, and such drugs had enabled thousands of animals suffering from pneumonia and other infections to be relieved and cured. It was conservatively estimated before the war that a quarter of the cows in milk were affected with mastitis, a disease in which sulphanilamide, if given in the early stages, brought about favourable results in from 60 to 90% of cases. Penicillin also gave promise in the treatment of this condition, as well as in infections caused by *Staphylococcus aureus* in the udder. The disease known as redwater in cattle, caused by parasites invading and destroying the red corpuscles, formerly took an enormous toll of life in most tropical countries, but by the use of trypan blue, a discovery due to experiments on animals, this loss and attendant suffering had been reduced to insignificance. Another parasitic blood affection, known in South Africa as East Coast fever, had yielded to preventive inoculation. The same was true of rinderpest, or cattle plague. As a result of intensive experimental research an immunization technique had been perfected and cattle plague totally eradicated from South Africa, where at one time it had threatened to exterminate all the cattle. This was not merely an economic gain, for cattle plague was an extremely painful disease to the animals themselves owing to the local lesions produced.

### Diagnosis and Control

Other diseases of cattle which had been controlled as the result of inoculation were anthrax and "black leg" or "black quarter," the latter due to a soil organism. It had also been demonstrated that vaccination of young heifers effectively prevented contagious abortion in cows. As for bovine tuberculosis, tuberculin had been shown by guinea-pig and cattle experiments to be a satisfactory diagnostic agent, and with its aid there was a good prospect that tuberculosis of cattle might ultimately be stamped out in this country. Among diseases of horses which had been largely controlled by experimental research Prof. Wooldridge mentioned glanders and tetanus; among diseases of sheep, lamb dysentery and "swayback"; and of pigs, swine erysipelas and swine fever. In dogs and cats experimental work on nutrition had resulted in the reduction of the incidence of rickets almost to vanishing-point. Prophylaxis had enormously reduced the incidence of distemper, while rabies in this country had been exterminated simply because, as a result of experimental research, its cause and mode of transmission had been discovered.

Prof. Wooldridge concluded by saying that it was abundantly clear that practically all species, at any rate of domesticated animals, had come to enjoy most remarkable benefits as a result of experimental research, and no veterinary surgeon could possibly do his duty to the animal world unless he took full advantage of the discoveries made by research workers.

<sup>1</sup> *British Medical Journal*, 1946, 2, 951.

<sup>2</sup> *Rev. sci. Instrum.*, 1946, 17, 345.

<sup>3</sup> *Brit. J. Radiol.*, 1946, 19, 481.

<sup>4</sup> *British Medical Journal*, 1947, 1, 594.

Yet, as a later speaker reminded the audience, the late Prof. Hobday was attacked by the anti-vivisectionists when he was carrying out his long series of experiments on the production of anaesthesia in domestic animals by means of inhalants such as chloroform and ether—experiments which put an end alike to the physical anguish of the animal patient undergoing operation and the mental anguish of the operator.

## INTERNATIONAL MATERNITY AND CHILD WELFARE

An international conference on maternity and child welfare was held in London during the last week of June. Delegates from many European countries, including Germany, Austria, and Italy, attended, and two of the sessions were devoted to a discussion of Europe, her present needs and future outlook, in which delegates from twelve countries participated. The Minister of Health, in opening the conference, referred to the gratifying fall in infant and maternal mortality in Great Britain. In 1946, when the birth rate was the highest for over twenty years, infant mortality stood at 43 per 1,000 live births, and maternal mortality at 1.43 per 1,000 births, or less than half the figure for 1938. The stillbirth rate was about two-thirds of what it was before the war. These advances, said Mr. Bevan, had been made because the Government was trying to ensure that such resources as were available reached those who most needed them. The improved vitality and "bonniness" of infants was also to be attributed to the higher standard of infant care brought about as a result of propaganda and the more intelligent devotion of the modern mother. He believed that still greater improvement could be effected through the planning of available resources, which was the aim of the National Health Service Act.

Mr. Bevan praised the work of voluntary organizations in this as in other fields, and said that local authorities in working out their new schemes would be wise to make use of voluntary organizations and to contribute towards their funds. Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health, who presided over the ensuing session, also stressed the useful part played by voluntary organizations. "We cannot do without voluntary organizations in this country," he said. "They have to be given as prominent a place in the new Health Service as they have had in the past. It would be a sad day for this country if voluntary work were to come to an end."

A discussion developed on the training of doctors and midwives. Sir Andrew Davidson, Chief Medical Officer of the Department of Health for Scotland, said that to gain adequate medical experience for maternity and child welfare work intending practitioners in this branch of medicine should divide their time between maternity and child welfare services, especially those which had a department for breast-feeding difficulties, nurseries which catered exclusively for healthy children, and sick children's hospitals. The singleness of the mother and child as a biological unit should always be kept in mind. Lady Reading urged that medical students as part of their training should attend infant welfare centres in order to see how doctors dealt with normal children.

### Nutrition of Mother and Child

In a session on nutrition Dr. H. E. Magee, adviser in this subject to the Ministry of Health, said that the national indices of the health of mother and child, which had been improving during the war, were checked in 1940-1, but since 1942 maternal, infant, and neonatal mortality rates had been falling. There was less anaemia among women and children in 1943 than in pre-war years, and there had been further improvement since then in some areas. The constructive and protective nutrient requirements of the expectant mother were almost entirely met by her rations and allowances alone, irrespective of canteen or other extra meals and the family pool, and the rations of the nursing mother and infant together provided more than enough of nutrients for both. He held that much of the improvement in the health of mother and child during

and since the war as compared with pre-war years could be attributed to better diet.

Of the reports made by Continental delegates the most encouraging came from Norway. Dr. Hanna Berghoff described the work of the Norwegian Women's Nursing and Health Association, which had 200,000 members (in a country with a population of only three million) and 300 stations for maternity and child welfare spread all over the country. The latest statistics for all Norway gave an infant mortality rate of 35.5 per 1,000 live births, and in Oslo in 1945 the rate was 21.2, the lowest ever recorded. It was stated that in Austria at the present time the question of providing milk for infants is the outstanding problem. In one maternity hospital in Vienna a collecting centre for mothers' milk has been established from which the bottled milk is taken daily to the homes where it is needed.

## PHYSICS IN THE LIFE OF A SURGEON

The Cavendish Lecture of the West London Medico-Chirurgica Society was given at Kensington town hall on July 1 by Mr. H. S. Souttar. His exposition was clarified by diagram and charts—the work of his own hand—one stretching almost half-way across the room and showing the range of radiation through more than sixty octaves, only one of which was visible light.

Speaking first of the physics of the human body, Mr. Souttar said that few were aware of the actual measurement of the forces which the muscles could exert or the exquisite precision with which the movements of the joints were controlled, a fact that was all that was required. By this cunning device of traction he induced the muscles to relax and exert no force at all, for he removed the source of irritation produced by the contact of the fractured ends of the bone. The lecturer gave a simple example of the important secondary effects of the forces which the surgeon employed. If traction were put on the femur of a patient lying in bed there must of course be some counter-pull to prevent the patient from being pulled out of bed, and this was most easily obtained by raising the bed foot. But this counter-pull acted on the centre of the pelvis, while the traction pull passed through the hip. The side of the pelvis was thus pulled down, so that the pelvis lay obliquely and the leg was effectively abducted at the hip. In the case of a fractured femur this was of no importance, but in many conditions of the hip-joint abduction was the essential point of treatment. It might be imagined that this was easily obtained by swinging the leg out, but that was by no means the case, as the pelvis might swing with it. Traction in the line of the leg was the correct physical method of obtaining abduction—a simple fact not always appreciated.

### Resistance to Forces

Mr. Souttar then turned from the forces which the human body was capable of exerting to those which it was capable of resisting. As an example he considered the effects of a blow on the head. If a man were struck on the head by a stone weighing 1 lb. (0.45 kg.) and falling a distance of 9 ft. (2.74 m.) he would probably have some degree of concussion, though his skull might not be broken. If it deformed the skull 1/4 in. (0.63 cm.), which was about the possible limit, any such deformation would be resisted by a rise in intracranial pressure which, in the example quoted, would be at least of the order of 80 lb. to the square inch (5.5 kg./sq. cm.). Such a pressure even though it lasted for only a fraction of a second, might force every drop of blood from the capillaries, leaving the brain anaemic, with the clinical result of instantaneous paralysis, furnishing a complete justification of Trotter's theory that phenomena of concussion were the result of sudden anaerobiosis resulting from the rise of intracranial pressure.

Mr. Souttar described a curious case which many years ago came under his care at the London Hospital. A small child was knocked down by a light cart and the wheel passed over her head. He cleaned up the dirty lacerated wound of the scalp and noticed a fine crack vertically through the temporal region. The condition of the child precluded any further disturbance. Two days later she regained consciousness, but after two days more she became comatose, with clear signs of intracranial pressure. He trephined and found beneath the hair-like crack not blood, as he had expected, but an extradural disk of hard mud 2 in. (5 cm.) in diameter and 0.5 in. (1.25 cm.) thick in the centre, and on removal of this the child made an uninterrupted recovery. This considerable mass of mud could have got in only through the crack, and as the force applied was only momentary the crack must have opened widely. He estimated that a force of 250 lb. (113 kg.) weight must have been supported on an area of 5 sq. in. (32 sq. cm.), so that the pressure within the skull must have been 50 lb. to the square inch (3.2 kg./sq. cm.).

Touching finally on another branch of physics—radiation—he said that x rays and gamma rays of radium had taken their place as established instruments of surgical technique, but to understand their use something must be known of their origin and nature. Both arose within the atom, but from very different sources. X rays were produced by hurling at the atom a stream of electrons driven by powerful electric forces; gamma rays arose from the disturbance of the electron field of the atom owing to the explosion of the nucleus of the atom itself. The radiation was identical in kind with x rays, but with x rays produced by an energy of two million volts. "I believe that in radiation we have one of the greatest weapons of surgical progress, but it is indeed a weapon and not a tool, and only those who are prepared to devote their lives to its study have any right to use it except in very limited fields or with the close co-operation of those who understand its dangers as well as its powers."

Beyond the region of the gamma rays there were the cosmic rays—far shorter and of correspondingly greater energy—arising, it was believed, from the actual destruction of matter and having their sources in the distant nebulae. It was certain that these rays had a profound influence on the cells of the human body, perhaps indeed were essential to life itself

## TEN YEARS OF WAR SURGERY

Dr. J. Trueta lectured to the Abernethian Society at St. Bartholomew's Hospital on June 19 on "Ten Years of War Surgery." This was one of the last lectures he is giving in this country before returning to Barcelona. Dr. Trueta was chief surgeon of a big industrial institution in Catalonia in 1929, and when the Spanish war broke out he became chief surgeon to the general hospital of that province, where he developed in a larger field what he had begun to try industrially—his technique for the treatment of compound fractures. He came to Great Britain in 1939.

In his lecture he pointed out that the experience gained in war had been the main factor in surgical progress for many centuries. War was of benefit to surgery, though this was not paralleled by its benefit to surgeons, because the work had to be done in a hurry under conditions of difficulty and improvisation, and good teaching, so essential to the training of a surgeon, tended to disappear in a war. He had built up for himself a code of principles, and in 1936, when the Spanish war broke out, he had started a propaganda campaign in Spain to endeavour to convince others of those principles. The main and decisive principle was the importance of blood supply. It was no use relying only on the sulphonamides: every bit of bad tissue must be removed. Penicillin, while the greatest of gifts to the good surgeon, was not of much use to the bad. There was a great deal of difference between the surgeon who relied only on these compounds and the one who meticulously removed every trace of damaged tissue. Bacteria were only 50% of the sepsis problem, the other 50% being the condition of the tissues.

With a war wound the pessimistic conception obtained that there would always be bacteria in contact with the damaged tissues. During the Spanish war there had been no sulphonamides and no penicillin, and yet the results were very much

better than they had been in 1918. In a series of 1,073 cases of compound fracture he had had only six deaths; two or three of the cases had come to him fifty minutes after bombing, but some as long as forty-eight hours after, having received no intermediate treatment at all.

The second important point was immobilization. Complete immobilization was essential; partial immobilization was worse than none at all. Plaster had two properties: it kept the limb quiet, and it protected the wound against contamination from outside. Up to that point he thought most surgeons would agree, but there was a difference of opinion among them on the drainage of wounds. He did not have pus from his wounds. He recommended the use of very close mesh dry gauze because it had absorbent powers and fulfilled the necessary duty of starving the bacteria. He had never once seen pus forming under dry gauze.

## COMMONWEALTH FUND FELLOWSHIP AWARDS

The committee of award of the Commonwealth Fund Fellowships (35, Portman Square, London, W.1) has made the following appointments to Medical Fellowships offered by the Commonwealth Fund of New York, which are tenable by British graduates in American universities for one year beginning September, 1947.

J. P. Bentley, M.B., F.R.C.S., Charing Cross Hospital Medical School and King's College, University of London, to Emory University, Atlanta, Georgia (in Surgery).

R. P. Brittain, M.B., Ch.B., LL.B., University of Glasgow, to New York University College of Medicine (in Forensic Medicine).

J. Innes, M.D., F.R.C.P.Ed., University of Edinburgh, to Washington University, St. Louis (in Medicine).

A. Slessor, M.B., Ch.B., University of Glasgow, to Harvard University Medical School (in Medicine).

H. Stalker, M.D., F.R.C.P.Ed., University of Edinburgh, to Cornell University Medical School (in Medicine).

## Preparations and Appliances

### THE SMALLEST HEARING-AID

A demonstration was given in London recently by the Multi-tone Electric Co., Ltd., of a hearing-aid said to be the smallest in the world. Its length is about 8 cm., its width about 4 cm., and with the small battery pack, into which the instrument may be plugged to form a single unit, it weighs only 160 g. The upkeep costs are from one penny for thirteen hours to one penny an hour, according to the degree of deafness. The new instrument is known as M.T.3, short for "midget telesonic three-stage." The three-stage amplifier consists of a space charge double tetrode and an output pentode, used as a pentode when a magnetic miniature earpiece is plugged in. A novel feature is the volume control switch, consisting of a differential condenser used in a negative reaction circuit. This, it is claimed, cannot go wrong or become noisy with age. Another advantage is that with the inductive load of the magnetic earpiece or bone conductor the higher frequencies are emphasized as the amplification is increased. An alternative response curve can be obtained by means of the tone control screw on the back of the instrument, operated by substituting a longer screw than the one with which the instrument is normally delivered. The telesonic system, with which the instrument may be used, was developed during the war as a means of local communication. The deaf person, it seems, has only to attach this hearing-aid to a small adaptor, which automatically cuts out the microphone from the circuit and converts the instrument into a telesonic aid, to be able to use it with the telephone or in buildings where the telesonic system is installed. The M.T.3 costs 30 guineas with crystal miniature earpiece and standard mould.

## Correspondence

### State Medical Service in New Zealand

SIR,—The letter from the pen of Sir Ernest Graham-Little (May 3, p. 611) invites comment. Your heading of "State Medical Service in New Zealand" is unfortunate and quite inaccurate. We have had a State salaried service in this country for many years looking after the mental hospitals, all of which, except one, are under State control. The scheme to which your correspondent refers, however, is simply a compulsory universal prepayed system whereby there is a more equitable distribution of that costly article, medical care. The only part the State plays is to collect the premiums and pay the doctor 7s. 6d. for each service rendered. It also pays the chemist for any drug ordered by the doctor providing it is one listed in the *B.P.* and *Addenda* or *B.P.C.*, and will even pay a portion of the cost of a proprietary equal to the sum payable for the official equivalent if such exists. It also pays all public hospital bills and similar sums to private hospitals, and all x-ray and laboratory facilities. Finally, it pays for immunization of school-children and provides the material free, so that now it is almost impossible to find a child who has not been immunized.

Nowadays people can get medical care for all conditions instead of having to self-diagnose and self-prescribe a patent medicine. Nowadays the doctors can and do order all sorts of laboratory procedures without wondering whether the patient can pay. And at last the profession, for the first time, have learned to think and prescribe in terms of official nomenclature and not in terms of a trade jargon covering a bewildering jumble of proprietary medicines, about the exact composition of which so many were profoundly ignorant. Yet, in spite of these and other great advances, we are told that the standards have dropped. Other people think differently. We are also told that patients cannot get attention at night and during the week-ends. I am sure that hundreds of G.P.s in this country will join with me in saying that this is grossly inaccurate and quite unjust. Certainly it is not true of the South. Finally, a dearth of specialists, if such really exists, could be readily explained by the increased amount of medical work consequent on discovering illness in people who previously could not afford medical attention. At any rate, as the general practitioner scheme has only been in operation for six years, it cannot have played any part in the alleged shortage. Furthermore, the difficulties of taking a postgraduate course in Great Britain at the present time are too real to need any stressing.

It is becoming rather tiresome to see stalwarts of organized medicine in America and Great Britain labelling this country as the Ugly Duckling in reports which are essentially superficial, misleading, and biased. If they must survey the New Zealand cenc, then it is only fair that they do it thoroughly and conscientiously. It will then be found that, while the present scheme is neither wholly good nor wholly bad, yet on points it is much in advance of the old system, and that the establishment of the sociological principle that medical care shall be free and universal is here to stay.—I am, etc.,

Wanaka, New Zealand.

ALBERT D. G. BLANC.

SIR,—The following extract from a letter which has just reached me from a university professor (non-medical) in New Zealand may be found interesting and suggestive:

"If you introduce your own State Service in England, you will probably be able to profit from our mistakes. A common objection is that a young practitioner without much ability can earn a good salary so soon that he has no incentive to specialize. . . . Moreover the system does not discriminate between men of superior and inferior qualities. The general opinion is that our best medical practitioners will tend to leave New Zealand to an even greater extent than before."

I think you will agree that the above stresses a tendency which needs to be borne in mind.—I am, etc.,

Weybridge, Surrey.

A. C. LANKESTER.

### Adder Bite

SIR,—In view of the fact that we have had two cases of adder bite within the last three months, we feel their case histories may be of interest. In both cases we tried the effect of "benadryl" to counter any allergic symptoms which might have arisen; in both cases this appears to have been effective. In the second case we were able to obtain anti-viperine serum, but injection was not possible until several hours after the bite, and its full value could not be assessed. In both cases there was a marked degree of shock, vomiting, and upper abdominal pain of considerable intensity. Recovery was uncomplicated, and both patients have reported no subsequent ill effects.

### CASE REPORTS

*Case 1.*—De B., aged 60, bitten by unidentified snake—an adder from his description—at the junction of the middle and lower third left shin, at 5 p.m. on April 11, 1947. No tourniquet applied, and patient travelled thirty miles before being seen by one of us (H.H.M.) at 7.30 p.m. By this time he was considerably shocked and vomited several times, complaining of severe upper abdominal pain. A cruciate incision was made into the site of bite until blood flowed freely. No tourniquet was applied because of the time lapse (24 hours) since the bite. The patient was given morphine 1/6 gr. (11 mg.), and the leg was immobilized between pillows. That night the patient developed swelling of lips and face; he was given benadryl 50 mg. by mouth, and the swelling subsided by morning. The following day, April 12, his leg began to swell, became brawny, and finally turned mottled blue and black up to and including the groin. This continued for one week with adenitis of left inguinal glands. On the second night his face and lips again swelled, and he was given 50 mg. of benadryl with good effect. His general condition continued satisfactory, the pain and swelling of leg after a initial three days' increase gradually subsiding, and he was discharged upon the tenth day with slight oedema of leg. On May 9 slight oedema still persisted at end of day.

*Case 2.*—P. T., aged 17, on June 17 found a snake coiled up under an earth bank. He picked it up, thinking it was a grass snake whereupon it bit him on the dorsum of his left thumb over the interphalangeal joint, at 6 p.m. His young brother tied a handkerchief tourniquet around base of thumb, but apparently not very tightly. He walked one and a half miles home, where he arrived in a collapsed condition. He was immediately taken to hospital. One of us (G.E.F.) saw him at 6.45 p.m. He was then in a very shocked condition, grey in colour, pulse very rapid and weak, vomiting repeatedly and complaining of severe upper abdominal pain. A cruciate incision was made into the site of the bite and intermittent venous occlusion of upper arm was commenced. By this time there was considerable local swelling and pain. Benadryl (100 mg. in 4 oz. (114 ml.) of saline was injected P.R. and 1/6 gr. morphine given. General condition improved, and at 1 a.m. on June 17 10 ml. of anti-viperine serum was given intramuscularly into left deltoid. After a restless night sulphadiazin (2 g. stat., 1 g. 6-hourly) was commenced and continued to a total of 20 g. Benadryl 50 mg. t.d.s. was given for two days. No allergic symptoms were reported. Brawny swelling of hand, forearm, and upper arm developed, with temperature up to 100° F. (37.8° C.) on first day. Swelling became maximum on third day, involving laterra chest wall and scapular region with axillary adenitis. Region of bite became bluish, with serous discharge. Recovery began on fourth day, and patient was discharged home with slight swelling but no pain on eighth day. June 30, reported fully recovered.

—We are, etc.,

H. H. MATHIAS,  
G. E. FRENCH.

Tenby, Pembrokeshire.

### Choice of Drugs in Treatment of Duodenal Ulcer

SIR,—I have read with interest the article by Dr. A. H. Douthwaite (July 12, p. 43) and in particular his remarks on the use of belladonna in the treatment of peptic ulceration. With him I agree that its effectiveness is undoubted, as indicated in my article on "Dyspepsia and its Surgical Significance" in the *Journal* of June 3, 1933 (p. 954). From my own studies of its effects its main action lies in the prevention of coeliac stimuli reaching the intestinal musculature, in particular the pyloric and other junctional sphincters. By doing so it relieves all stomach excitability. The unfortunate feature in its administration, as pointed out in my article, is the low concentration in the tissues which produces the distressing subjective symptoms of dry mouth and ocular disturbances. An adequate and long course of therapy is required if permanent cure is to be reached.—I have not met the patient who will submit to it.

In the surgery of dyspepsia—and surgery is frequently required—it is essential in many cases that pre-operative treatment be often long and even trying, and it was this feature that led me in my search to discover the value of bromide combined with other aids in the treatment of dyspepsia.—I am, etc.,

Dundee.

JOHN J. ROBB.

### The "Costoclavicular Syndrome"

SIR.—Might I be permitted to make an addition to Mr. M. A. Falconer's valuable letter (July 12, p. 69) on this subject? At operations where the axillary inlet is displayed in the living subject it can easily be shown that depression and retraction of the shoulder cause diminution of the space between the clavicle and the first rib; downward traction of the arm also causes the subclavian artery and lower trunk of the brachial plexus to come into more intimate contact with the uppermost rib. Both these facts can be observed when operating for other conditions on patients who do not complain of the "costoclavicular syndrome."

In fact we are all potential sufferers from compression of the neurovascular bundle in the axillary inlet. Under normal circumstances the arm is only held in the position of strain for relatively short periods; also the natural mobility of the neurovascular bundle allows it to move out of harm's way. If, owing to a number of causes such as congenital abnormalities, loss of mobility, continued postural strain, dropping of the shoulder girdle, etc., compression is long continued, the "costoclavicular syndrome" results. As already stressed, there is no one mechanical cause: symptoms are often due to a combination of causes; therefore, if the symptoms and signs are severe enough to warrant operation, exploration must be thorough.

Secondly there is considerable variation in the exact relationships of the subclavian artery and the components of the brachial plexus. I believe it is the relative vulnerabilities of the artery and nerves which determine whether vascular or nervous symptoms predominate.—I am, etc.,

Liverpool.

R. ROAF.

### Spinal Pumping

SIR.—In your annotation entitled "Spinal Pumping" (July 12, p. 62) you refer to the work of A. D. Speransky, which lies "buried in the Russian tongue." We feel that attention should be drawn to the following facts. The first English translation of Speransky's work *A Basis for the Theory of Medicine* was published in New York in 1935, and was reviewed in your issue of Feb. 8, 1936, p. 263. In this volume the theoretical basis of "pumping" is elaborated, though the reader who is anxious to discover it must be prepared to follow to its conclusion a difficult and lengthy presentation.

However, all the important original papers which constitute the basis of the work appeared not only in Soviet journals but also in German publications (chiefly the *Zeitschrift für die Gesamte Experimentelle Medizin*). Since 1933 isolated papers have also appeared in the *Acta Medica Scandinavica* and other non-German journals.—We are, etc.,

JAMES B. BRIERLEY.  
E. J. FIELD.

University of Bristol.

SIR.—Your annotation on spinal pumping (July 12, p. 62) was somewhat unfortunate in its choice of metaphors. We are told that Soviet medicine, untouched by contemporary medical thought, has been developing behind the only too familiar "iron curtain," likewise that the work of Speransky—one of the most illustrious of Soviet medical scientists—remains "buried in the Russian tongue." But if contemporary medical thought is somewhat absorbed in the study of antibiotics then surely Soviet scientists, by their contributions in this field, particularly with reference to gramicidin, show a similar interest.

With regard to the "iron curtain," the library of the Royal Society of Medicine appears to be well stocked with current Soviet medical publications. It is true that they are mostly untranslated, but is the *B.M.J.* sent to Moscow already printed in the Russian language? It would seem that what is needed here is not a liberal use of threadbare clichés but some diligent and purposive organization. As for Speransky remaining buried

in the Russian tongue, I would recommend your annotator to refer to the *B.M.J.* of Feb. 8, 1936 (p. 263), where the first English edition of Speransky's book *A Basis for the Theory of Medicine* is reviewed, albeit most inadequately. The book was published in English in 1943 by International Publishers, U.S.A.

In his book Speransky gives a very detailed account of the long years of experimental work which eventually led him to formulate—however tentatively—a new attitude to disease processes. Just as it is to be hoped that the results achieved by Gillman and Gillman working along these lines will stimulate others to try the method, so it is even more important for Speransky's basic experiments to be checked on the widest possible scale so that his conclusions may either be rejected or further developed.—I am, etc.,

London, N.W.11.

J. S. HORN.

SIR.—With reference to the annotation of Speransky's method of spinal pumping (July 12, p. 62), I should like to correct an error. Your annotator states: "... the steps that led him to adopt this bizarre method of treatment remain buried in the Russian tongue." Speransky's book *A Basis for the Theory of Medicine*, which contains the information your contributor is after, has been available in English since 1935, and has been in the library of the Royal Society of Medicine for several years to my knowledge. A second edition (1943) is available through any bookseller from the International Publishers, New York.

The question again rises: "Who is responsible for the iron curtain—us or the Russians?"—I am, etc.,

London, W.2.

A. W. LIPMANN KESSEL.

SIR.—In the *Journal* of July 12 (p. 62) there is an annotation on the subject of experiences in treating rheumatism and rheumatoid arthritis by the method called spinal pumping. It sounds from the annotation that this odd treatment was carried out only once on each patient. Is this correct? Naturally if a series of lumbar punctures had to be performed on each patient the procedure would be much more hazardous and less impressive. I should be grateful if you would clear up this point for me.—I am, etc.,

Reading, Berks.

K. D. SALZMANN.

\* Gillman and Gillman pumped their patients once, twice, or three times, according to requirements. They comment in their article referred to in our annotation: "First, a single spinal pumping can be followed by lasting beneficial effects; secondly, when a relapse occurs it is usually not as severe as the original attack; and, thirdly, if spinal pumping induces salutary effects on one occasion then a second or even a third pumping is indicated in the presence of refractory joints or if a partial relapse occurs."—Ed., *B.M.J.*

### Stress Fractures of the Metatarsals in Childhood

SIR.—With reference to Dr. Lewis D. Rutter's article on "Stress Fracture of a Metatarsal in a Young Child" (July 12, p. 5) I should like to quote a case which attended the orthopaedic clinic here over one month ago.

The father brought his child of 3 to us complaining that she was not walking properly, and that she walked on her heel with the intent of saving the fore part of her right foot. Examination revealed some puffiness on the inner side of the foot. Tenderness was doubtful. X-ray examination showed a cuff of new bone formation round the mid-shaft of the third metatarsal, with some subperiosteal new bone formation spreading proximally and distally along the shaft. No fracture line was visible. A differential diagnosis of march fracture and Ewing's tumour was arrived at, a case of the latter having been seen previously in the metatarsals of a child of 9 years. Also with Ewing's tumour in mind, the child was asked to be seen 3 weeks later, and in the meantime weight-bearing was to be restricted. X-ray examination on June 30, 1947, showed a definite fracture line, and the diagnosis was then quite obvious. There was then consolidation at the site of the fracture. The child was walking better and tenderness was completely absent.—I am, etc.,

Scunthorpe, Lincs.

ELIZABETH C. MCCLURE.

**Nicotinamide and Diabetes Mellitus**

SIR,—In the *Journal* of June 14, which I have just received on my return from holiday, I noticed a letter from Dr. W. Gordon (p. 863) in reply to my short memorandum on the subject of nicotinamide and diabetes mellitus (March 29, p. 414). I must hasten to correct the erroneous impression under which Dr. Gordon appears to be labouring—namely, that I am in charge of the Diabetic Clinic at Salford Hospital. This is not so, and my observations on the use of nicotinamide in diabetes mellitus were carried out in my capacity as chief assistant to Prof. T. H. Oliver, at Manchester Royal Infirmary, and were not performed at Salford Royal Hospital. I shall look forward with interest to the publication of further observations on this subject by Dr. Gordon, particularly to learn how an increased production of insulin, which he attributes to nicotinamide, may occur without affecting the sugar tolerance curve.—I am, etc.,

Manchester.

H. J. WADE.

**General Knowledge and General Practice**

SIR,—The reasons for the "distressing lack of culture" in medical students and doctors are the same as those to be found elsewhere. The average boy about to study for one of the professions has a father who is tacitly admitted to be on a lower level of culture than that which the son hopes to reach. Such boys are brought up in households where leisured and informed conversation on a variety of subjects is unknown. From school age onwards they fight against time and examiners. They have no time to read widely, to think deeply, to travel, to make the acquaintance of well-informed persons, and to become aware of their own ignorance. They are caught young and soon begin to know more and more about less and less.

The remedy is early selection, alleviation of financial anxiety, a higher and later standard of general education, and the rising of the age of registration. Our declining civilization cannot provide this. What does the British Medical Association suggest as a palliative?—I am, etc.,

Cricklade, Wilts.

T. R. THOMSON.

**Advice to Lay Committees**

SIR,—I feel I should report a difficulty in connexion with my work as psychiatrist in charge of the child guidance clinic of a local authority which raises a question of principle. The facts are briefly these: A short time ago I recommended that a patient of mine, an 8-year-old boy, should be sent to a boarding school and, with the mother's agreement, put it forward as a case eligible for assistance from the authority under section 8 (2) (d) of the Education Act, 1944. After much delay and repeated applications an interview was finally arranged, first between myself and two members of the authority's education committee, and then between these members and the child's mother. I was then informed that the committee had rejected the application.

The question of principle involved should be of great concern to the doctors who will next year be brought into close relationship with lay committees. The point at issue is whether, or in what circumstances, a lay committee is entitled to reject specialist medical advice.

In this particular case, the distinction between the function of the committee and of the medical officer was perhaps less clear than in some. The Education Act lays it down that local authorities may assist in the costs of boarding school education for those children whose parents wish for it and for whom the authority considers boarding school education desirable. It is a reasonable view that the "authority" is the elected representatives of the people; but the question is, how should these elected representatives form their opinion? On many matters the only basis is the advice of their technical experts. This would be accepted by all were the advice to be, for instance, sanatorium treatment from a tuberculosis officer, surgical treatment from an orthopaedic specialist, or convalescence from a cardiologist. The difficulty in the present case, leading to confusion of thought, is that the advice was not for any highly

technical treatment. It is therefore assumed that the decision is not come to on the basis of technical or specialized knowledge.

I have not specified here, because I could not without betrayal of confidence, and I did not specify fully to the committee, my reasons for this recommendation. It was, however, based on study of the case carried out over many months, and the recommendation for a change of environment was made because I had reached the conclusion that the environment was responsible for the child's condition. The committee may doubt the wisdom of the advice tendered. The medical adviser may be wrong. It is not part of my argument that I was right—merely that I formed my opinion with information, knowledge, experience, and training not available to laymen. If my conclusions were doubted, was not the correct course for my committee to call for further, and more expert, medical advice?

This particular dispute arose in the relatively new field of psychiatry, where the special qualifications of the doctor may be suspect. Similar difficulties can, and undoubtedly will, arise in other fields unless doctors now face these problems, clarify and define their functions as the servants of public bodies, and work to see that these are understood and respected.

I am, Sir, a supporter of the National Health Service, and in that service the role of lay committees as spokesmen for, and protectors of, the public will be indispensable; but I now see, and stress the danger, that lay committees may interfere with medical treatment, not from lack of good will but from lack of understanding. If we do not now collectively act to prevent this, our patients will suffer, while each individual doctor squanders his substance and his enthusiasm fighting his individual battle.—I am, etc.,

London, W.C.1.

PORTIA G. HOLMAN.

**Local Executive Councils in N.H.S.**

SIR,—The Regulations (S.R. and O., 1947, No. 889, Part I, 4 (2 and 3)) relating to local executive councils state that one-third of their total number of 24 members (excluding the chairman) are to retire every year and that the order of retirement is to be decided by lot. By this method it is possible that all the seven doctors, or the three dentists, or the two pharmacists *en bloc* may have to retire in the same year.

I think, myself, that this is not the real intention of the Regulations. I believe that it is intended that every electing body should have, as far as possible, an election every year. If this view is correct I suggest that the drawing of lots for the order of retirement should be carried out in sections. Thus considering the professional half of the council alone, first of all the three dentists should each in turn draw one of three papers marked one, two, or three; then the two pharmacists should each draw from three similar papers; and finally the seven doctors should each draw from two papers marked one two marked two, and two marked three, together with the one paper left over after the pharmacists have made their draw. In this way, one dentist would retire each year, one pharmacist in two years out of the three, and two doctors in two years and three doctors in a third year.—I am, etc.,

Leeds.

J. H. E. MOORE.

**Royal Civilian Medical Corps**

SIR,—It is now almost five minutes to twelve, the chalk lines have been drawn on the parade ground, and the markers are taking up their positions. Is it too late to suggest again that it does not require the conscription of the whole profession and the creation of a vast medical trust, with its wastage of scarce resources and its problems of organization and integration almost beyond the wit of man, to ensure that the poorer members of the community shall not be deprived of aid through lack of means? The formation of a Royal Civilian Medical Corps would effect the most precise adaptation of means to an end, both as regards the Government and the profession. Those members who favour a hierarchical medium in which to express themselves, those who have the power urge, those who feel they have latent administrative ability, those who love uniforms, badges of rank, decorations, regular mealtimes.

# Vitamin Therapy—its uses and limitations

## GROWTH REQUIREMENTS IN CHILDHOOD

The relatively high metabolic needs of growing children must be met not only by energy-producing foods, but also by the factors needed for their metabolism, namely vitamin B<sub>1</sub> (aneurine) and the co-enzymes of the vitamin B<sub>2</sub> complex. Failure to supply these may be revealed in poor growth, debility, abnormal fatigue. Such a combination is highly suggestive of a deficiency of the factors—vitamins, protein, minerals—so richly supplied by Bemax.

### BEMAX

*Stabilised cereal embryo*

1 oz. of Bemax provides approximately:—

Vitamin B <sub>1</sub>	0.45 mg.	Vitamin E	8.0 mg.	Protein	30%
Vitamin B <sub>2</sub> (Riboflavin)	0.3 mg.	Manganese	4.0 mg.	Available Carbo- hydrate	39%
Nicotinic Acid	1.7 mg.	Iron	2.7 mg.	Fibre	2%
Vitamin B <sub>6</sub>	0.45 mg.	Copper	0.45 mg.	Calorific Value	104

*References: Shortage of space precludes list of references but full documentation may be obtained on application to Clinical Research Dept. 27 A.*

**INCREASED  
SUPPLIES**

Chemists now receive sufficient Bemax to ensure that all prescriptions are met.

## Anginal Pain

In view of the now generally accepted theory that the pain of Angina Pectoris is due to myocardial anoxaemia, a potent coronary vasodilator, such as Cardophylin, may be of value in relieving the anoxaemia when this is due to an inadequate blood supply to the myocardium, especially where coronary constriction is the main factor in interfering with the blood supply.

## Cardophylin

A SPECIALLY PREPARED COMPOUND OF THEOPHYLLINE-ETHYLENEDIAMINE

### INDICATIONS

ANGINA PECTORIS, CHEYNE-STOKES RESPIRATION, PAROXYSMAL NOCTURNAL DYSPNOEA, CARDIAC ASTHMA, OEDEMA

In Tablets of 0.1 g. for oral use.

Ampoules for intra-muscular injection 0.4 g. in 2 cc.

Ampoules for intra-venous injection 0.24 g. in 10 cc.

Suppositories each containing 0.36 g.

LITERATURE & SAMPLES ON REQUEST.

**Ensign**  
FILM

pensions, pagantry, and privilege would surely welcome the establishment of such a corps. Volunteers would not be lacking.

From the Government side there would be the immense advantage of having a disciplined permanent cadre ready for an immediate switch in the event of war, the movement of doctors about the country would be facilitated, the difficulties of incorporating remote hotted camps within the present hospital service would be resolved by the formation of parachute troops, and whole divisions could be hurled at will into medically neccessitous areas.

There would be corps d'élite bearing the names of distinguished leaders: the 1st Bourne Brigade, the Ryle (Duodenal) Division, the Black (Eye) Guards, the Stark Murray Chinwits are only a few of the suggestions which spring to mind. Regimental traditions would develop, and in times to come the veterans of many campaigns would forgather in their beta-screened concrete clubs to show their operation scars and fight over again their old battles with disease, real and imaginary. What heroic tales would be told to stir the blood of the young men (subject to the approval of the State haematologist)—the Colonic Lavage Campaign of 1950, the Preventive Raid of 1952 (a blunder this, based on erroneous information from intelligence as to the cause of the falling birth rate, but none the less glorious), and the mysterious Accidie Revolt of 1955 among the survivors of the middle classes, which was finally defeated by the Hormone (Injection) Division.

The problems of organization are large but not immense. These and the avoidance of duplication of services are surely not insuperable obstacles to those who feel themselves gifted in large-scale overall planning with "blue-prints," "items of service," and all the other semantic devices which now pass for thought. All that is required is the idea and the will. Forward the Brigadiers!—I am, etc.,

Bournemouth.

T. R. AYSLEY.

### Standard of Nursing Education in U.K.

SIR,—I am directed by my Council to draw your attention to a letter which has been received from the executive secretary of the Registered Nurses' Association of British Columbia cancelling the existing agreement for reciprocal registration of nurses between this Council and the Association, as it is felt by the Association that the improvements in standards of nursing education in this country, both in respect of general educational qualifications required for entry to the nursing profession and in respect of the nursing training received, have not kept pace with those in British Columbia, and that in fairness to members of the nursing profession in British Columbia and to the public which has come to expect a higher standard of nursing it is not possible to continue the reciprocal agreement entered into with my Council in 1934. In the reply which my Council has sent to the executive secretary of the Association it has been pointed out that, although the hours of instruction a student nurse is required to have undergone before entry to the examinations in British Columbia are considerably in excess of the minimum numbers of lectures laid down by my Council for entry to the examinations in this country, the majority of training schools do in fact arrange for many more lectures to be given than the required minimum, and that, taking into account clinical instruction, tutorials, and revision classes which do not appear on official record sheets, the actual hours of instruction and the variety of clinical experience afforded to most student nurses in this country do approximate much more closely to those in British Columbia than would appear from a comparison of the respective minima laid down. In view of the fact, however, that the General Nursing Council is being pressed from certain quarters to lower its standards of training still further it is felt that attention should be drawn to the fact that nursing education standards in this country would already appear to be falling below those in the Dominions, and that the letter from the Registered Nurses' Association of British Columbia is a timely reminder of the urgent necessity to raise rather than lower the standards of nursing education in this country.—I am, etc.,

M. HENRY,

Registrar.

London, W.1.

General Nursing Council for England and Wales.

### Myopathy with Spina Bifida

SIR.—Dr. Ronald G. Paley (Jan. 11, p. 53) points out the coincidence of the combined occurrence of spina bifida and myopathy. As this association is seldom found, which a perusal of the literature on this subject during the last 25 years indicates, Dr. Paley suggests that it is only an accidental association.

I am not entirely in accordance with the opinion that the status dysraphicus, to whose syndrome belongs the spina bifida, is due to chance concurrence. In 1942, in a review on myotonias (Thomsen and Steinert—diseases and myotonia acquisita) I described 6 cases out of 14 that presented spina bifida. The others, with only one exception, showed different abnormalities in the vertebrae. Later, Passouant (1943) found 3 patients with dystrophica myotonica in a total of 5 cases with spina bifida. The appearance of such skeletal abnormalities in myopathic cases were known by different authors, and in this respect Hirschfeld in 1925 points out the necessity of a more profound analysis in order to elucidate its significance and causal importance. Consequently I feel inclined to accept the idea that the status dysraphicus can be found more frequently at least in certain myopathies than in normal human beings (10% according to Curtius and Lorenz), and that it represents a favourable genotypic milieu for the occurrence of phenotypic myopathies.—I am, etc.,

Buenos Aires, Argentine.

ALFREDO LANARI.

### Calculation of the Colour Index

SIR.—Dr. W. K. Taylor's letter (July 5, p. 33) is regrettable. The value to the patient is the criterion for the use of any laboratory investigation. Should haematocrit determinations be of enough use in the diagnosis or the treatment of disease, the haematologist must be prepared to perform them even at the risk of becoming a "mathematical robot."

Dr. Taylor states that values for the colour index outside the range 0.9 to 1.05 are probably pathological. In R. G. Macfarlane's study of the error of the Haldane haemoglobin estimation (M.R.C. Special Report Series No. 252, London, 1945, p. 59) the variability of 60 trained observers was studied; 12 had coefficients of variation such that a normal colour index could give values exceeding Dr. Taylor's range (allowing  $\pm 2 \sigma$ ) from variation in the haemoglobin alone without making any allowance for the quite considerable variance of the red-cell count. Finally may I suggest that a nomogram is merely an aid to calculation. Dr. Taylor should construct and use his own nomograms. Was it entirely fortuitous that one of the best photographs of the late Sir Frederick Gowland Hopkins showed him seated in his laboratory holding a slide rule?—I am, etc.,

Sheffield.

ARTHUR JORDAN.

SIR.—Dr. William K. Taylor's arguments (July 5, p. 33) against my suggestion of discarding the conception of the colour index are not easy to follow. Some of them are directed against windmills. Against his opinion that the colour index is a valuable guide to treatment I would say that I should not be surprised if, by and large, the amount of liver extract needlessly administered at private or public expense on the basis of a colour index above unity irrespective of anything else would exceed that given with a properly established indication. Any method of reporting haematological findings which avoids this pitfall and which tends to force the recipient to think in a less facile manner seems thereby alone worthy of consideration.

Regarding the use of a nomogram, Dr. Taylor's twice uttered dictum that a scientist using such a device will thereby convert himself into an automatic machine might have been apposite in a poem condemning time-sparing inventions but sounds a little odd in a note where reasoning is expected to follow logical rather than magical rules. His view that "any improvement in . . . haematology should follow the lines of establishing specialist haematology departments in hospital laboratories" (italics are mine) implies that progress in this subject is not

likely to be achieved by clinicians. With the notable exception of the field of immunology such an opinion is scarcely substantiated by past experience, and there seems no reason to doubt that future progress will similarly be shared between clinicians and pathologists.—I am, etc.,

London, E.2.

HERBERT LEVY.

### Insulin Treatment for Schizophrenia

Sir,—In the *Journal* of May 31 (p. 779) a letter by Dr. L. F. Donnan was published in which it was stated that I had informed the writer that the relapse rate after insulin treatment for schizophrenia is greater than in those cases which recovered spontaneously. This statement was not made by me to Dr. Donnan or to anyone else.

Insulin treatment of schizophrenia has been carried on in this hospital for the last ten years, and the results go to show that it is by far the most successful form of treatment for schizophrenia. Schizophrenia does not differ from any other form of disease in that a certain proportion of cases that have recovered relapse. The experience of this hospital goes to show that the rate of recovery is much greater in cases treated by insulin than by any other method and that the relapse rate shows no proportionate increase.—I am, etc.,

Dublin.

JOHN DUNNE.

### On Complete Removal of the Prostate

Sir,—Following perusal of Mr. H. S. Souttar's article (June 28, p. 917) it seems to me that many surgeons lacking experience in prostatic surgery might be led to try the procedure he describes, with results which would be far from beneficial, and in fact might be disastrous, to the patient.

The very first paragraph of Mr. Souttar's article contains assumptions regarding the extravesical approach which are not generally accepted. The extravesical approach does not present considerable advantages over the transvesical methods; the post-operative period is not shorter and easier and bleeding is not more readily controlled. Mr. Souttar seems to have no wide experience of the modern operations (Harris, Hey, or Millin) which make possible immediate closure of the bladder. It seems a retrograde step to consider substituting the difficult and probably dangerous technique he describes for these comparatively simple and safe methods, but it might have a place in the eradication of early prostatic carcinoma, and indeed some months ago I heard Mr. Millin describe a technique for this condition somewhat similar to that now described by Mr. Souttar.

It seems strange that Mr. Souttar should be unaware of the correct spelling of Mr. Millin's name; one presumes that he is referring to Mr. Terence Millin.—I am, etc.,

Glasgow.

WALTER W. GALBRAITH.

### In-patient Treatment of the Maladjusted Child

Sir,—In reply to the letters of Drs. W. H. Whiles (June 21, p. 898) and J. A. McCluskie (July 5, p. 29), I would like to say that since the article was written we have now a special children's admission villa in the grounds of the hospital in addition to the annexe already described. This villa, which is entirely self-contained, possesses a pleasant garden and also an area of about 1/6 acre, which is fenced off and in which the children have plenty of scope for outdoor play.

Incidentally, however, with regard to the particular point raised by Dr. McCluskie as to the effect of chronic psychotic females on the children, I can assure him that matters were not at all as he anticipated. In fact, several of these ladies manifested much more tact, forbearance, understanding, and consistent handling of the children than is exhibited by the average parent. The point of course does not arise now that there is no longer any contact between the children and adult patients in the hospital. I must explain to Mr. G. A. Foulds (June 21, p. 898) that the article was written on very general lines and was only meant to give an outline of the work. As regards the child with the intelligence quotient of 170, this point was only included to indicate the fact that some of the children at least can be classed as brilliant. The test, which was form L of the Terman-Merrill Revision, was not carried

out at this hospital, but a few months later a similar test on form M gave the result of 159.

It may be helpful to add that the term "returned home" indicated that the child was fit once more to live a normal life in his own home environment, and when it is realized that 95% of these children were unable to do this despite adequate out-patient treatment, not only in this city but in some of the best-run child guidance clinics in the country, I think it will be appreciated that the "benefit" was not inconsiderable.—I am, etc.,

Portsmouth.

W. LIDDELL MILLIGAN.

### Causalgia of the Face

Sir,—Mr. J. A. W. Bingham (June 7, p. 804) is to be congratulated on his neat demonstration of a possible afferent path for painful sensation in the cervical sympathetic. Most surgeons dealing with the sympathetic nervous system for causalgic states, advanced Raynaud's disease, and particularly erythromelalgia are probably led to much the same opinion, but few have so definitely advanced the matter towards final solution. Mr. C. H. Cullen (July 5, p. 32) might like to consider a recent article by Dr. Threadgill, which in general supports Mr. Bingham's thesis by some interesting animal experiments and supplies the basic references.—I am, etc.,

Dublin.

PATRICK FITZGERALD.

### REFERENCE

Threadgill, F. D. (1947). *Surgery*, 21, 569.

### Health of Young Workers

Sir,—Dr. C. H. Hoskyn (July 5, p. 29) invites further opinions on the subject of health supervision of juveniles in industry, and as I have for some years past undertaken such work as part of my duties as an industrial medical officer I can say with confidence that a close liaison between school health services and industrial health services is of great importance. This point has been emphasized in a recent paper entitled "The Change from School to Industry" (Lloyd Davies, T. A., and Newth, A. A. E., *Public Health*, 1947, 60, 177), and if it is agreed that a knowledge of the conditions and environment under which the young person is to work is essential to enable a satisfactory assessment to be made of his fitness for the occupation which he seeks to enter, then clearly the industrial medical officer is the person to carry out the examination.

Under Section 48 of the Education Act, 1944, a duty is imposed on the local education authority to "provide for the medical inspection at appropriate intervals of pupils in attendance at any school or county college maintained by them," but such supervision has long been carried out by the medical services in progressive firms, and indeed forms one of the most satisfying duties which fall to the lot of the industrial medical officer.

Under Section 69 of the Education Act, 1944, the Minister is empowered to make Regulations about the conduct of medical examinations for the purpose of the Act and provision may be made "requiring that any class of such examinations or inspections shall be conducted by duly qualified medical practitioners having such special qualifications or experience as may be duly prescribed." I would have thought that the special knowledge and experience of the industrial medical officer would have enabled him to play a useful part in this work, perhaps as a part-time officer of the school medical service.—I am, etc.,

Ripley, Derby.

GERALD F. KEATINGE.

Sir,—In the publication *School and Life* (H.M.S.O., 1947) the Central Advisory Council for Education (England) has made certain recommendations on the supervision of health during the early years of employment, and Dr. C. H. Hoskyn (July 5, p. 29) rightly draws attention to the challenge these recommendations make to industrial medicine, the main concepts and developments of which were summarized in your leader "Whither Industrial Medicine?" (June 14, p. 853). While the recommendations of the Central Advisory Council apply particularly to England and Wales, the pattern of legislation to-day is such that, should the responsible Minister accept them, they would be adopted for the country as a whole. Accordingly

they require, at this juncture, examination by all those engaged in the practice of industrial medicine and interested in juvenile health.

Many of the suggestions made in the report are excellent, and industrial medical officers will welcome the proposal for a closer liaison and freer interchange of records and information with the school health service. It is indeed unfortunate, however, that the Central Advisory Council should make such sweeping and novel recommendations on the supervision of juvenile health in industry without examining the many excellent schemes already in operation and without full discussion with the doctors administering such a service. The complete supervision by one doctor from the nursery school age till the age of 18 years is an admirable conception. This should be the joint responsibility of the family doctor and the school health service. The Council propose that the medical officer in the school health service be required to obtain a specialized knowledge of child life to carry out work in school clinics, to be attached to a children's hospital, and to maintain close liaison with the school nurse. If these services are to be efficient, then they will constitute a wide field of study and a whole-time specialty. To widen such a field, by adding to it the supervision of the health of the juvenile in the factory, suggests that the Council do not appreciate the conception of a doctor in industry and fail to realize that he is not only a works doctor but an important member of the personnel organization.

In order to play his full part in such an organization the doctor requires a thorough postgraduate training, with experience in general practice and in hospital. It is preferable that he should hold a higher medical qualification or the diploma in industrial health. He must also have an intimate knowledge of the factory environment, of the various manufacturing processes carried out, of the industrial hazards involved, of the financial inducements and other rewards for the day's work, of the home environment of the employees, and of a multitude of other factors.

It is essential, as in the case of the school child, that the responsibility for the juvenile in industry be a joint one with the family doctor and the industrial medical officer working in close liaison, but because of the latter's experience and position in industry I believe that he is best suited to maintain that close liaison, so essential to the success of any scheme, between the family doctor, the certifying factory surgeon, the school health and education services, the specialist hospital services, and the executives of industry. In the light of those conceptions I suggest that the supervision of juvenile health in industry be entrusted to the medical and welfare services already in existence.—I am, etc.,

Glasgow.

WILLIAM HUNTER.

### History of Arab Medicine

SIR,—I read with interest what Prof. Major Greenwood had to say (March 8, p. 314) about my comments (Feb. 1, p. 202) on the late Dr. Neligan's quotation of Browne's *Arabian Medicine*. Permit me to use the same source, from which I cite the following: P. 26: "... he who judges Arabian Medicine only by the latter [its Latin translations] will inevitably undervalue it and do it a great injustice [Leclerc]." Browne states that during the period of translation the Arabs already possessed a copious anatomical vocabulary (p. 30). This would suggest an advanced stage of medical knowledge; and (p. 112), "... still the question remains whether the Arabs did more than transmit the wisdom of the Greeks, and whether they added much original matter to the scientific concepts of which for some eight centuries they were the chief custodians." This, Browne believes, is not an easy question to answer, and much laborious research is needed ere it can be answered definitely (such research work is being sponsored by the Palestine Arab Medical Association). P. 113: "And it must be said once and for all that no just idea of Arabian Medicine can be derived from the very imperfect Latin renderings of the standard Arabic works;" and p. 115: "On all these grounds, then, even if we rate the originality of Arabian Medicine at the lowest, I venture to think that it well deserves more careful and systemic study." Thus does Browne himself modify the statement requested by Prof. Major Greenwood.

From *The Arab Heritage*, Faris (Princeton University, 1944, p. 243): "It is now generally understood in certain specialized circles of competent historians of medicine that the early patterns of hospitalization and hygiene in Europe received

their energizing impetus from Arab medical science." In *Meet the Arab* the well-known Arabist, my learned friend Dr. Vann Ess, of Iraq, referring to Arab contributions to science says, "A very substantial achievement which has in fact put all of us Occidentals permanently in debt," and "A century of translation, though itself conspicuous for marked achievement, was but a prelude to the original contributions made by the Arabs." Works of many of these Arabs were of such significance, as they, in the words of Van Ess, "By their own efforts contributed in making medicine a science indeed."

The second point raised by Major Greenwood was that I assured him that the Christian church regarded belief in infection as heretical. The passage reads: "such heretical statements in Europe might have brought on the vengeance of the Church and perhaps cost the life of such a heretic." There is nothing new in this statement. Disease being a visitation from God, it would be heretical to attribute it to other mundane causes. The Church maintained, for example, that even the prevention of pain during childbirth was contrary to religion and the express command of the Bible. This conception the staunch Scotsman Simpson in 1847 fought; and his "Answers to the religious objections against anaesthesia in midwifery and surgery" is a masterpiece. Simpson maintains that opposition on theological grounds had been presented against every humane innovation in medicine, such as vaccination. Smallpox, they said, "is a visitation from God, but vaccination is produced by presumptuous and impious man: the former Heaven ordained, the latter a daring and profane violation of our holy religion." And lastly Servetus, a contemporary of Vesalius (16th century), because of his courage to maintain that the blood passes from one side of the heart to the other, through the lungs, as in fact it does: in consequence of this heresy his books were confiscated, and he was himself burned at the stake.—I am, etc.,

Jerusalem

I. B. GEORGE.

### Lectures from Edinburgh

SIR,—In recent years great stress has been rightly placed on the need for closer links between the preclinical and clinical parts of the medical training, and among other things one assumes that these include some reference by the clinical teachers to those physiological findings which have a direct bearing on their subjects. Some questions of interest with regard to this are raised by the letter of Dr. Edwin Bramwell (May 24, p. 741) on the *Edinburgh Postgraduate Lectures in Medicine*, in which Dr. Bramwell reveals that the Edinburgh lectures are published with the aid of a grant from the trustees of the Honyman Gillespie Fund, under which animal experiments may not be referred to.

As it is not altogether clear what is implied by this statement, I would be grateful for some enlightenment on the following points. (1) Is it to be understood that, although the Honyman Gillespie Fund cannot ordinarily be used for reference to animal experiments, special permission has been granted in this case, or was the Honyman Gillespie Fund available for publication of these lectures because they were considered to be free from the offending references? If the former interpretation is correct no further explanations are necessary, and Dr. Bramwell is to be congratulated on overcoming a prejudice so detrimental to progress in medical science. If, however, the second interpretation is the correct one the following further questions arise. (2) Does the present volume contain only those lectures which do not refer to animal experiments, omitting those which do, or are all references to animal experiments in the postgraduate teaching at Edinburgh forbidden? (3) Does this mean that clinical teachers who wish to refer to animal experiments are prevented from taking part in the postgraduate teaching at Edinburgh? (4) Since in fact reference is made to animal experiments in some of the lectures, does this mean that the lecturers are prevented from describing only their own animal experiments? (5) If one of the purposes of the publication of the lectures is to enable practitioners "to keep abreast of the times," why does the Edinburgh School place itself under a censorship which prevents reference to modern physiological progress?—I am, etc.,

Sheffield.

D. H. SMYTH.

## Primary Treatment of Fingertip Injuries by Skin Grafting

SIR.—This is not a new method of treating this type of injury, but it has not received the attention which it deserves. As a rule, when skin loss has occurred and suture cannot be effected, skin flaps are fashioned and a formal amputation, often involving removal of the whole of the distal phalanx, is performed. I have treated a number of such injuries by primary skin grafting within the first eight hours with excellent results. The method is simple and, with a little practice, quite rapid and easily carried out in the casualty department. Normally the fingertip wound has clean edges, a variable quantity of soft tissue being lost. When the edges are ragged, limited excision of the ragged edges and necrotic and heavily soiled tissues is carried out, and bone fragments projecting above the surface level of the wound are trimmed off with bone forceps. Any further operation producing shortening of the digit is avoided.

## TECHNIQUE

Digital block anaesthesia is produced using 2% procaine without adrenaline. Haemostasis is secured and the digit covered with a sterile towel while the graft is cut. The skin of the front of the forearm is cleansed with soap and water, and a suitable area large enough to cover the raw fingertip is infiltrated with 2% procaine containing 1 in 1,000 adrenaline. Using a sharp scalpel and a pair of fine rat-toothed forceps, a full thickness graft is cut exactly to the size required and subcutaneous fat carefully removed. Several small holes are cut in the graft to allow for the escape of blood and serous exudate. The graft is then stitched into position over the fingertip wound, using atraumatic needles threaded with gossamer silk. Strict haemostasis is not essential with this type of graft, since firm pressure is maintained by the sutures and final pressure dressing. A light sprinkling of penicillin in sulphathiazole powder is blown on to the surface of the graft and the site covered with a small square of tulle gras; this in turn is covered with sterile gauze soaked in saline.

It is essential that the graft be kept moist, particularly in the early stages, as it is nourished by the tissue fluids within the first twenty-four hours. Some authorities use a dressing which can be continuously irrigated through small-bore rubber tubes without disturbing the dressings. The pressure dressing employed in my cases consists of a pack of cotton-wool soaked in saline moulded to the fingertip and held in position by a light plaster-of-Paris splint. In the absence of pain or of a raised temperature this dressing is left in place for fourteen days. After this time the graft should have taken firmly and present a healthy pink appearance, although a small surface slough is usually present. The sutures are removed, and further sterile dressings are applied for fourteen days, when as a rule no further dressings are required. The arm wound is dealt with by undercutting the edges and suturing them together. This presents no difficulty in view of the small size of graft usually required.

No hard and fast rule can be laid down for dealing with a damaged nail if present. In general it can be said that where a good part of the nail remains it is best left to grow over the dorsum of the graft. When, however, the whole of the nail has been avulsed and the nail bed lacerated, it is probably better to remove any remaining remnants of nail bed and cover the whole raw area with the graft.

After six to twelve months sensation has returned in good measure and a useful finger, unshortened, is left. The fingertip thickens and forms an appreciable pulp in about six months. I have found that split-skin grafts are not nearly so satisfactory as the full-thickness grafts, because they are difficult to hold in place, and when healed they usually present a thin sensitive scar on the fingertip. The percentage of takes secured is remarkably high—in my cases about 80%, if the injury is dealt with within the first eight hours and gross obvious sepsis is not present.

Should the graft not be satisfactory because of gross soiling, etc., a first-rate dressing will have been applied, and subsequently amputation or other methods of treatment can be carried out in a clean field. As a primary treatment skin grafting is worthy of a high place in dealing with fingertip injuries and could be much more widely used than at present.—I am, etc.,

S. J. KRISTER.

## POINTS FROM LETTERS

## Shortage of Nurses

Major R. H. MUMFORD, R.A.M.C. (Nr. Pontefract, Yorks), writes: Without wishing to express an opinion as to the merits of using Service-trained workers to alleviate the present shortage of nurses, I want most emphatically to repudiate some remarks made by "Ex-Q.A.R.N.N.S.R." (June 21, p. 903) regarding V.A.D.s. . . . During the recent war it was my good fortune to see much of V.A.D.s at work, especially during a period of over two years during which I was O.C. of a unit which depended on them for most of the nursing. My memories are not of the clumsy quacks pictured by your correspondent but of cheerful, conscientious, and efficient workers whose efforts consistently gave satisfaction to the patients they nursed and the doctor in charge. . . .

S.B.C.P.O. H. ROSTON writes: I have followed with interest the correspondence in the *Journal* on the "Shortage of Nurses" . . . I am sure that "Surgeon Commander R.N." was referring to the continuous service sick berth staff, who received an intensive course of 11 months' training and then continued to serve in many phases for 12 or 22 years. During the war years it was a necessity to reduce the training period of staff and V.A.D.s, with the unfortunate results quoted by the two nursing sisters, and I am sure that "Surgeon Commander R.N." did not mean that these nursing orderlies be granted State registration without further training. I realize that the Nursing Council will allow Service trained orderlies to take the State examinations when they have completed the necessary training, but unfortunately, as in my own case, a draft prevents the candidate from being at the examination centre at the times fixed by the Nursing Council. After serving 12 or more years most men are married and have family responsibilities, and therefore cannot take up training in civilian life for financial reasons, but surely after 12 years' experience and passing examinations for higher rating they should not be lost to the country during this shortage of nurses because they do not receive full civilian recognition. I am sure that in time the Service examinations will be brought into line with those of the General Nursing Council, but in the meantime what is to happen to men like myself who, after 12 years of nursing experience all over the world, return to civilian life? . . .

Surgeon Commander, R.N., writes: Dr. R. Howell Roberts (June 21, p. 903) has misunderstood me. I expressed a private opinion about the present shortage of civilian nurses, and he need not complicate the issue by dragging in the late Lord Nelson. We are short of nurses in civil life now. There are many experienced nurses in the country who will not come forward under the present conditions but might consider doing so if action were taken on the lines which I suggested (May 24, p. 740). The future training of Service nursing personnel is another matter, complicated by the National Service Act, but might be modified if a proper approach were made by the General Nursing Council to the respective authorities. In fact all long-term nurses in the Services are encouraged to sit for their S.R.N., but attendance for examination at a distance from their places of duty is often impracticable. Ex-Q.A.R.N.N.S.R. (p. 903) will remember that one of her primary duties as an officer of the Royal Naval Nursing Service was to train and supervise the work of those under her, and I am sure that none of the V.A.D.s or S.B.A.s for whom she was responsible would have failed in their duty as did the unfortunate girl whom her sister met in the Army. Recommendation for registration of ex-V.A.D.s would of course devolve upon the respective matrons in-chief, who would be careful not to flood the market with undesirables.

\* \* This correspondence is now closed.—ED., B.M.J.

## Coroners' Inquests

COUNTY CORONER writes: In the preamble to an analysis of a series of cases of sudden death (July 12, p. 51) Dr. Robert Richards compares the private inquiry of the procurator-fiscal in Scotland with the inquest of the English coroner. He finds the former "a procedure possessing certain advantages over the coroner's inquest," but leaves his readers in the dark as to what they are. Perhaps he will enlighten them in a further communication, especially those in this country who practise forensic medicine and deprecate the private inquest no less than the private post-mortem examination.

## Game and Tsetse Fly

Dr. GEORGE PRENTICE (Fort Jameson, N. Rhodesia) writes: It may have escaped your notice that at a meeting of East and Central Africa Fauna Conference held at Nairobi in May it was decided that game should be destroyed in areas affected by the type of tsetse fly which transmits sleeping sickness. . . . Where varieties of tsetse exist that are not yet incriminated, other experiments are to be made. That is taking risks but may have some justification. . . .

## Obituary

ALEXANDER GAVIN MORISON, M.A., M.D., D.P.H.

The sudden death of Dr. Gavin Morison, Medical Officer of Health of Wembley, at the early age of 54 robs the public health service of a skilled leader and the doctors and people of the borough of a true friend.

When he came to Wembley Morison brought wide experience of preventive medicine in Bristol and Bolton, and also of general practice. He had been Port Medical Officer to Bristol, where he got great satisfaction from housing work in slum areas, and he had served in the Navy during the war of 1914-18. Morison came to the rapidly growing borough of Wembley ten years ago, when the old idea of public health as a necessary nuisance was dying; the time was ripe for a leader with exactly his gifts to develop the new ideal. This he did with outstanding success, in spite of the severe handicap of a stroke which occurred almost immediately after he took up office. It is a tribute to his courage and tenacity and to the wise care and companionship of his wife that he worked unremittingly for ten years without ever letting his health interfere with his duties. These were no easy years in a big, expanding borough subjected for more than half that time to the stresses of war. Another man might with less reason have excused himself, but Morison never failed to turn out, day or night, to every bombing incident. The memorial he built was a highly efficient public health department with every general practitioner his ally and friend. Local doctors knew what he was doing and what he wanted them to do. Their problems were made easy and their difficulties swiftly overcome by his skilful organization and by his personal help. Patients never found themselves mere cases. They realized at once that, whatever had to be done to safeguard the public, they remained people whose lives and interests Morison had immediately made his personal concern.

Morison was a gentle man with great tact and patience. Sympathy was inherent in him; he did not need to turn it on for occasions. No matter how foolish a question might be, he never showed anything but the gravest interest, gave the problem most careful thought and the applicant a wise and courteous answer. The gentle hesitancy with which he put forward his views disguised a profound and extensive knowledge of his job.

It is tragic that Morison should have died on the eve of the introduction of the National Health Service, when his special gifts of tact and tolerant guidance will be needed so much. The people of Wembley and their doctors have lost a real friend, and they share in deep sympathy that loss with his widow and daughter.

Mr. JOHN DANIEL HARMER died suddenly at George, South Africa, on June 25, at the age of 69. He graduated M.B., Ch.B. at Edinburgh in 1905, gaining first-class honours in all subjects. In 1903 he had been the most distinguished student of his year in anatomy, winning the gold medal in this subject. He subsequently held house appointments at the Royal Devon and Exeter Hospital and at the Leith Hospital. His outstanding ability was soon recognized by those for whom he worked. Prof. R. J. A. Berry endeavoured to persuade Harmer to continue with his studies in anatomy as a member of his staff, but Harmer was more attracted to surgery, and in 1909 became F.R.C.S.Ed. In the first world war he joined the R.A.M.C., and as a surgeon specialist saw service in France, Mesopotamia, India, and Africa. In the last year of the war he was posted to Rhodesia, and on demobilization he transferred to the Colonial Medical Service in that colony. In Northern Rhodesia he gave of his best for twenty-one years as a surgeon specialist, and was fond of recalling how in his early days there he would travel by horse, mule, or ganger's trolley to see his patients, and then how in his "old age" he started to make use of the aeroplane for his professional visits. He was awarded the O.B.E. in recognition of his outstanding work in Rhodesia. He had been a member of the B.M.A. for forty years and was president of the Northern Rhodesia Branch from 1933 to 1936. Although retired he joined up in the R.A.M.C. in the recent war, but had to resign his commission owing to ill-health. Nothing daunted, he asked to be sent abroad to relieve a medical man

for active service, and was then sent again to South Africa. Undoubtedly his selfless service in the war injured his health and hastened his demise. Harmer never spared himself, and endeared himself to patients and colleagues everywhere he went. It was indeed a privilege to know "J.D."

T. N. P. W.

The sudden death of Dr. MICHAEL JOHN MURRAY on July 5 came as a great shock to all who knew him. Born in Greenock in 1888, he graduated at Glasgow University in 1912, and while there was prominent in student affairs as President of the University Irish Nationalist Club. In the 1914-18 war he served in the R.A.M.C. in Gallipoli and later on the North West Frontier in India. He was twice mentioned in dispatches. On his return from war service he settled in Dundee, where he practised for 26 years until the time of his death. He was happily endowed with a cheerful personality, coupled with a deep sense of sympathy and understanding, which endeared him to his patients; his qualities of mind and heart commanded the respect of all who came in contact with him. The National Health Service, with its many problems, could not but appeal to one so intimately concerned with the interests of his profession and the well-being of the community. A sound debater and capable of forceful comment, he threw himself whole-heartedly into the solution of these problems and took a prominent part in many medico-political discussions during the past few years. His colleagues confirmed him in their regard by electing him Chairman of the Local Medical and Panel Committee and Representative to the Representative Body. He was also a member of the Scottish Subcommittee of the Insurance Acts Committee from 1943 to 1945. His untimely death is deplored by all and robs the community of a colourful personality and the medical profession of a loyal and beloved colleague. In the words of one who knew him well, "he was truly a great man, and his natural capacity for making friends was surpassed only by an even greater capacity for keeping them." We mourn his loss and extend our sympathy to his widow and family of three.

The death of WILLIAM EVERETT, F.R.C.S.Ed., on June 15 was briefly noticed in the *Journal* of July 5. A colleague, "C. J. P.," adds the following appreciation: Winchester loses an outstanding personality whose loss will be felt by all sections of the community. His health had not been good for some years and he had a number of painful illnesses which he had borne with great fortitude. Although he himself was aware of all the possibilities arising from the condition from which he suffered, he faced the future with great courage and his cheerful aspect made the shock of his passing all the greater for those who were not aware of the true state of affairs. A native of Edinburgh, Everett was a senior medical student at its university when war broke out in August, 1914. His patriotism would not allow him to wait to complete his medical qualification, and within a few days of the outbreak of war he volunteered to serve in the ranks of the R.A.M.C. Shortly afterwards he embarked for France and saw service with the British Army until 1916. In that year a shortage of qualified medical men became apparent and he was recalled from the Army to complete his medical studies at Edinburgh. Qualifying in 1917, he joined the Royal Navy as a temporary surgeon-lieutenant and was posted to a Q "mystery" ship in the Mediterranean. After a period of considerable hazard he was transferred to the Naval hospital in Bermuda, where he was in charge of the surgical division and x-ray department. On his way to Bermuda he was delayed in New York, and was "captured" by the Americans to take part in their War Loan Campaign. In this effort his speeches were successful in raising large sums of money for the war. On demobilization he returned to Edinburgh to resume his studies, took the F.R.C.S., and was awarded the University Prize for Pathology. From Edinburgh he moved to Bradford, where he held the post of senior resident at the Bradford Infirmary. He was later appointed resident surgeon at the Barry Accident Hospital, where he remained for four years. After a period in consulting practice in Cardiff he moved to Winchester in 1929. Here he was soon appointed a member of the honorary staff of the Royal Hampshire County Hospital, and he quickly established a reputation as a surgeon. As a diagnostician he showed a careful, balanced judgment, and he readily obtained the complete confidence of his patients. As an operator his profound knowledge of anatomy combined with sensitive and dexterous hands enabled him to undertake the most intricate and delicate operations with success. At the time of his death he was senior honorary surgeon at the County Hospital. This institution always claimed a foremost part in his affections; and anything which he could do to forward the welfare of its inmates or staff was readily done.

William Everett was a man of high ideals and of great moral courage. Allied with his outstanding skill in his profession was his imaginative sympathy for patients under his care—and indeed for everyone who was in trouble. Many in the humbler walks of life have special reasons to be grateful for acts of kindness, happily conceived and quietly performed. He was very fond of children and was particularly successful in gaining their confidence and affection. He was an artist of skill, and had considerable gifts as a lecturer and teacher. As a colleague he was loyal, staunch, and considerate, and was ever ready to respond to appeals for help and advice. Everett was a man of wide culture and a delightful companion. To anyone privileged to enjoy his happy hospitality, it was very apparent how much his home life meant to him and in what affection he held his wife and children. To these, his many friends in all walks of life will extend their warmest sympathy.

## Medico-Legal

### DIVORCE AFTER TEMPORARY INSANITY

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Under Herbert's Act divorce may be granted where a party to the marriage is incurably of unsound mind and has been continuously under care and treatment for five years immediately before the petition. "Care and treatment" are clearly defined. A person of unsound mind is deemed to be under care and treatment while he is detained in pursuance of any order or inquisition under the Lunacy and Mental Treatment Acts, 1890-1930, or while he is receiving treatment as a voluntary patient, if that treatment follows without any interval a period of detention in pursuance of the kind of order already described, "and not otherwise." The result is that if a patient starts his treatment as a temporary patient under the Mental Treatment Act and then changes to voluntary status he does not come within the Act, and the partner cannot have a divorce for insanity.

This anomaly was shown by a recent case<sup>1</sup> in which a wife, shortly after bearing a child, showed signs of mental disorder and was admitted to a mental hospital as a temporary patient. Six months afterwards, at her own written request, she was admitted at the same hospital as a rate-aided voluntary patient. Ten years afterwards she was still there and quite incurable. The husband petitioned for a divorce, but the judge found himself unable to grant a decree because the period of voluntary treatment followed detention, not in pursuance of any order or inquisition, but under the temporary provisions of the 1930 Act. Before the wife was admitted as a temporary patient the husband had signed a form, as prescribed by the Act, requesting the superintendent to receive his wife as a temporary patient. This application was duly accompanied by the appropriate recommendation of two medical practitioners. Counsel for the husband argued that if a patient may be lawfully detained for six months without his or her consent as a person of unsound mind it must be presumed that the detention was imposed by virtue of some legal order. The Court of Appeal replied that this attractive proposition was based on the assumption that all the safeguards provided by the 1930 Act to ensure that the patient is properly detained are scrupulously complied with. The Master of the Rolls<sup>2</sup> laid down in 1940 the principle which the courts apply in these cases. He said that the safeguards which the legislature has laid down to ensure that detention shall take place only in proper cases are strict, and unless they are strictly observed the detention of an alleged lunatic is illegal. The machinery must be carried out according to the letter of the law. Now the 1930 Act lays down that within a month of the reception of a temporary patient he shall be visited by two members of the visiting committee, and if they think he should continue to be detained they must sign a statement to that effect and leave it with the person in charge; if they think otherwise they must before the end of the second day report their opinion to the Board of Control. The state-

ment or report of the visiting committee is therefore an essential requisite for the lawful detention of the temporary patient.

The judge trying the case at first instance had no evidence before him about what the visiting committee did, and decided the case on the ground that the temporary treatment procedure does not contain either an order or an inquisition. The Court of Appeal had inquiries made and ascertained that the visiting committee had not signed the required statement to the effect that it was proper that the wife should continue to be detained. The letter of the law had not been carried out; the wife was not lawfully detained, and the husband, therefore, through no fault of his own, could not have his divorce. This result points clearly to a need for the revision of Herbert's Act to bring its provisions more into line with common sense.

It is worth noting that if the voluntary treatment follows immediately on a further period of temporary detention, the "care and treatment" provisions of Herbert's Act are satisfied because the temporary detention is prolonged by an "order" even though it has not been initiated by one: *Benson v. Benson* (1941).

## The Services

The President of the U.S.A. has conferred the Legion of Merit degree of Officer, on Lieutenant-Colonel D. A. O. Wilson, R.A.M.C. in recognition of distinguished services in the cause of the Allies.

The Queen of the Netherlands has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

*Knight Officer of the Order of Orange Nassau with Swords.*—Major (Temporary) R. Strang, R.A.M.C.

*Knight of the Order of Orange Nassau with Swords.*—Captains J. N. Blair and F. G. Tucker, R.A.M.C.

Dr. Saw Ba Tin, Medical Officer, Kyaaukkyi, Burma, has been appointed M.B.E. (Civil Division) for services to the Forces during military operations in Burma prior to Sept. 2, 1945.

### R.A.M.C. PRIZE FUNDS: THE CONSULTANTS PRIZE

The consultants to the War Office and the Armies in the Field in the late war have presented a sum of money to the R.A.M.C. in order to found a Consultants Prize, to be competed for at intervals of one to three years. The prize will be awarded for the first time in 1948 and will be to the value of 25 guineas; it is open to serving officers of the R.A.M.C. holding a regular or a short service commission. The first prize will be awarded for an essay of not more than 10,000 words on a professional subject, based on the author's own experiences between 1939 and 1946. It is hoped that these essays will ensure that valuable war experience, which would otherwise be lost, will be recorded for future guidance and possibly for publication. Entries should be sent in through the usual channels so as to reach the honorary secretary, R.A.M.C. Prize Funds Committee, R.A.M. College, Millbank, London, S.W.1, by Aug. 1, 1948.

The Colyer Prize was founded in June, 1926, to commemorate the twenty-five years' service of Sir Frank Colyer as honorary curator of the odontological museum of the Royal Society of Medicine, and the following regulations were approved: That the accumulated income of this fund be used every third year for the purpose of awarding a prize for the best original work in dental science completed during the previous five years by a dental surgeon educated at any duly recognized dental school in Great Britain or Northern Ireland, and who has not been qualified to practise more than five years at the date of the award; that notices be sent to each dental school in Great Britain and Northern Ireland stating the conditions and the date at which the next prize will be offered; that the chief medical and dental journals be asked to give publicity to the announcement of the prize without incurring the fund in the expense of advertisement; that the prize committee shall have power to withhold the prize if they consider there has been no work submitted of sufficient merit to justify the award; that if the prize committee decide to withhold the award they shall be empowered to arrange for a lecture, or lectures, upon some subject related to the odontological museum and may accord the lecturer an honorarium from the prize fund. Applications from candidates, together with a general account of their researches, should be submitted to the Prize Committee of the Society (1, Wimpole Street, London, W.1) not later than Oct. 1, 1947.

## Medical Notes in Parliament

### Vaccination of an Infant

Mr. DRIBERG on July 15 drew attention to a mishap to an infant child of a family at Hatfield Peverel, Essex. At the age of 4 months the child was vaccinated. The vaccine did not take on the first occasion and she was vaccinated three times within seven weeks. The father alleged that on the third occasion the child was vaccinated with a double injection. On the fifth day after this third vaccination the baby was suddenly taken ill and was found to be suffering from what was described as an inflammation of the brain. Some weeks later she was returned to her home blind and not developing in any way. She suffered constantly from fits. Two children's specialists had seen her but said there was no hope of her recovery.

Mr. BEVAN expressed deep sympathy with the parents. No fault whatever attached to the doctors concerned and there was no departure from normal practice. There was no evidence whatever of carelessness or uncleanness. He rebutted the suggestion that there were two insertions at one time. Over seven weeks there were three insertions, the first two unsuccessful and the third successful from the point of view of inoculation. That happened frequently. There could be no imputation against the professional skill of the doctors concerned or against the way in which they carried out their duties. Post-vaccinal encephalitis did occur but was so rare that it amounted to one case in 49,000 inoculations. It would be deplorable if the publicity given to this case frightened parents from having their children vaccinated. It was doubtful whether the baby's condition was due entirely to post-vaccinal encephalitis. There were other possibilities which he did not wish to emphasize. Mr. Bevan pointed out that when the Health Act came into operation, compulsory vaccination would disappear. Relying on the laws of probability it appeared to him that there was some association between the comparative immunity from smallpox enjoyed by the mass of the population and the use of immunization and inoculation.

Replying to Col. Stoddart-Scott, Mr. Bevan said he understood that the serum used had been tested and there was no evidence of any abnormality. In fact there was no evidence at all of any unusual circumstances.

Mr. SOMERVILLE HASTINGS asked if an examination had been made into the health of the parents and also whether the figures given by Mr. Bevan of the number of cases of post-vaccinal encephalitis were of the total vaccinations or of primary vaccinations.

Mr. Bevan said he was informed that encephalitis was extremely rare in primary vaccinations of infants under the age of 1 and also extremely rare in revaccinations of adolescents or adults who had been vaccinated in infancy. It was somewhat less rare in primary vaccination of school-children and adolescents who had not previously been vaccinated. Even in these patients it was uncommon. In the last year for which figures were available this infection occurred at the rate of 1 in 49,000 vaccinations of all classes. There had been no investigation of the parents in this case.

### V.D. in Army

Answering Mr. Wilson Harris on July 15, Mr. BELLENGER said the annual rate of incidence of venereal disease in the British Army in Britain recorded during 1938 was 11.7 per 1,000. In 1946 the annual rate per 1,000 troops in Britain was 32.8, and in B.A.O.R. 158.6. The quarterly rate for the first quarter of 1946 was 5.3 per 1,000 in Britain and 30 per 1,000 in B.A.O.R. This was slightly lower in Britain than for the corresponding quarter of 1946, but approximately the same in B.A.O.R. In 1938 there was probably less recording of cases than in 1946, and modern medical practice, which treated the cases much more quickly than it did in 1938, probably accounted in part for the apparently higher incidence.

### River Pollution

A discussion on river pollution was initiated by Mr. HAROLD DAVIES on July 16. He said that nine-tenths of the water which fell on the surface of England was made useless by river pollution through discharge of untreated domestic sewage into streams and the failure of industrial undertakings to render effluent harmless. Consumption of drinking water was continually increasing. In a few years London would need from 15 to 60 gallons of water per head per day. If the rivers were not polluted water could be drawn from them to serve

the towns. Was the Government aware of the possible effect of effluent reaching the rivers from atomic energy factories?

Mr. MALLALIEU said the Fishery Board Report for the River Lume for 1945 said that into that river a minimum of 60,000 gallons of crude sewage was discharged every mile every 24 hours.

Mr. JOHN EDWARDS, replying for the Ministry of Health, said the Government shared the concern that there should be widespread improvement in the condition of the rivers. There had been a deterioration in the state of the rivers during the recent world war, though not on the same scale as during the first world war. The difficulty did not lie in lack of powers but in the impossibility of providing labour and materials for extensions or improvements of sewage disposal works and the fact that the authorities did not exist to make effective use of the powers in existence. Improvement of existing systems of sewage disposal was most important. With the urgent need for electricity stations and gas plants and for housing, what could be expended on sewage schemes was at present limited. It was unfortunate that too many industrialists were indifferent and often sought refuge in some old privilege rather than face a clear social responsibility to deal with waste products. There was no short-term remedy for river pollution, but the Government was preparing for the time when the country would have materials and labour necessary for the job and authorities powerful enough to enforce the law.

### Bubonic Plague

Mr. CREECH JONES stated on July 16 that in the outbreak of bubonic plague in Palestine up to July 15, 15 cases had been treated, only one of which had been fatal. Heavy and widespread infection among the rat population was reported, but energetic measures had been taken and no new cases had been notified since July 8.

*Medicinal Alkalis.*—A shortage of alkaline powder for medical purposes is due to shortage of bismuth metal. Every effort is being made to obtain increased supplies of bismuth.

*Coroners' Courts.*—Mr. Ede can hold out no prospect at present of amending the law relating to coroners' courts.

*Free Meals.*—Provision of free meals to children attending occupation centres set up under the provisions of the Mental Deficiency Acts will be sympathetically considered when the scheme for the supply of free meals to school-children is in operation.

*Nurses in Forces.*—Sisters and nurses still on duties connected with the Army number 2,531, of whom 1,581 are serving overseas.

*Hospital Beds.*—The number of hospital beds in Scotland, including beds in mental hospitals and in mental deficiency institutions, is approximately 62,600. The corresponding figure for England and Wales is approximately 469,300. These figures do not include beds in convalescent homes, about which full information is not at present available.

*P.O.W. Rations.*—Ration scales are laid down which are applicable to all prisoner-of-war camps in this country. Each camp is inspected approximately every two and a half months by an officer from the War Office.

*Schools for Deaf.*—Under the Handicapped Pupils and School Health Service Regulations, no child may be admitted to a school for the deaf unless an adequately qualified and experienced medical officer approved for the purpose has examined him and found him to be suitable for education in such a school. In all schools for the deaf arrangements must be made for the medical inspection, supervision, and treatment of the pupils.

*Surgical Dressings.*—The production of surgical dressings and gauze was in part interrupted by the fuel crisis but is now adequate to meet essential needs. The Ministry of Supply is inquiring into the difficulties said to be met in obtaining supplies for Scottish hospitals.

*Children's Soap Ration.*—In the present shortage of fat, Mr. Strachey cannot extend the extra soap ration for babies to children up to the age of 2 years.

*Supplies for Germany.*—There are no limitations on the dispatch of vitaminized concentrates and domestic medical supplies from the United Kingdom to Germany other than those applying to dispatch of such goods to foreign countries generally.

*Medical Services in Tobago.*—In reply to a recent question, Mr. Creech Jones said that in Tobago paupers and old age pensioners received free medical treatment. Persons in possession of a poverty certificate from the local administration or from public assistance authorities paid 1s. the receipt for which entitled them to medical treatment for a fortnight.

## Universities and Colleges

### UNIVERSITY OF OXFORD

In a Congregation held on June 26 the following degrees were conferred:

D.M.—J. M. Walker, G. S. Dawes.

### UNIVERSITY OF CAMBRIDGE

Mrs. Amy M. P. Pantin, M.B., B.Chir., has been elected to the Gwyneth Pretty Studentship for three years from March 25.

### UNIVERSITY OF DURHAM

At Congregations held on July 1 and 2 the following medical degrees were conferred:

M.D.—P. B. Crone, W. A. S. Falla, C. Neubauer, Mary D. Taylor, \*J. H. Middlemiss, \*S. G. Siddle, \*P. Szekely.

PH.D. IN MEDICINE.—\*S. Ali.

M.B., B.S.—J. P. Anderson, A. Ashcroft, G. M. Bell, Joan Bride, Sheila M. Cameron, D. J. Cawthorne, Lucy E. Coates, R. Cowley, Jacqueline Elliott, L. H. Field, Peggy Foster, J. B. Fox, J. Glaser, D. L. Golightly, A. C. Griffith, W. P. Haigh, A. Hand, B. Hayes, Catherine V. Jones, A. J. Jones, A. R. Kirby, H. F. Lake, T. K. Lamballe, Elizabeth L. Lee, W. L. Lee, J. L. Lee, L. L. Lee, M. McLeod, Margaret A. Nattrass, A. O. O'Neill, M. Roper, J. Roper, D. Roper, A. A. Reid, M. C. Robson, A. I. Royle, J. N. S. Simpson, Patrick M. Skellern.

\*K. McKay, \*R. I. Parr, \*W. E. Sumner.

\* In absentia.

### UNIVERSITY OF WALES

The following candidates for the degrees of M.B., B.Ch., at the Welsh National School of Medicine have satisfied the examiners at the examinations indicated: *Surgery*, A. J. Dark, H. B. Davies, Margaret E. Davies, Marjorie J. A. Davies, J. A. Emanuel, T. R. Hunt, H. E. Jones, J. G. Leopold (with distinction), Constance A. M. Llewelyn. *Medicine*, D. R. Bowen, Elizabeth B. Butler, J. P. Ciantar, A. C. Coulthard, A. J. Dark, G. C. Davies, Marjorie J. A. Davies, G. S. Foster, C. Havard, C. H. L. Howells, Eluned K. Jones, H. T. Jones, Rosina E. Jones, W. R. King, J. G. Leopold, L. T. Lewis, R. M. Marshall, Margaret I. Morgan, Vivien J. Parker, F. I. Powell, L. T. Rees, S. Solomon, Heather Stockdale, K. P. Williams.

### UNIVERSITY OF DUBLIN

John Kay Jamieson, M.B., C.M., has retired from the Chair of Human Anatomy and Embryology at Trinity College, Dublin.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a quarterly meeting of the Council of the College, held on July 10, Sir Alfred Webb-Johnson, Bt., was re-elected President for the ensuing year and Sir Cecil Wakeley and Mr. L. E. C. Norbury were elected Vice-Presidents.

Invitations to become the first Fellows in Dental Surgery of the College were issued to eighteen dental surgeons, including the following who are also members of the medical profession: Prof. Robert Vivian Bradlaw, M.R.C.S., L.R.C.P., L.D.S., Eric Wilfred Fish, C.B.E., M.D., D.D.Sc., William Kelsey Fry, C.B.E., M.C., M.R.C.S., L.R.C.P., L.D.S., Prof. Humphrey Francis Humphreys, O.B.E., M.C., M.B., Ch.B., M.D.S., Prof. Thomas Talmage Read, F.R.F.P.S., L.D.S., Harry Thomas Roper-Hall, M.B., Ch.B., M.D.S., Prof. Harry Stobie, F.R.C.S., L.D.S., Prof. Frank Clare Wilkinson, M.D., D.D.Sc.

The Council issued invitations to 21 dental surgeons to serve as the first members of the board of the Faculty of Dental Surgery of the College. The design for the gown for Fellows in Dental Surgery was approved.

The following appointments were made for the ensuing year:

*Hunterian Professors*—Mr. A. W. Badenoch, one lecture on congenital obstruction of the bladder neck; Mr. A. D. Beattie, one lecture on the treatment of peptic ulcer by vagotomy; Mr. D. J. Browne, one lecture on hare lip and cleft palate; Mr. M. A. Falconer, one lecture on a study of principles and results of lumbar intervertebral disk surgery; Mr. Hassan Ibrahim, one lecture on bilharziasis and bilharzial cancer of the bladder; Mr. Robert Guy Pulvertaft, one lecture on repair of tendon injuries in the hand; Mr. V. H. Riddell, one lecture on carcinoma of the breast; Mr. F. E. Stock, one lecture on the surgical approach to hypertension; Mr. A. H. C. Visick, one lecture on a study of the failure after gastrectomy; Mr. S. A. Way, one lecture on the anatomy of the lymphatic drainage of the vulva and its influence on the radical operation for carcinoma; Dr. M. C. Wilkinson, one lecture on observations on the pathogenesis and treatment of skeletal tuberculosis; Mr. H. W. Wooley, one lecture on the surgical treatment of malignant disease of the pharynx and oesophagus.

*Arris and Gale Lectures*.—Dr. E. M. Darmady, one lecture on acute uraemia, its aetiology and basis for treatment; Mr. L. Gillis, one lecture on recent advances in the treatment of arm amputations, cineplastic surgery, and arm prostheses; Mr. H. F. Lunn, one lecture on a contribution to the anatomy of hernia.

*Erasmus Wilson Demonstrators*.—Six demonstrations on the pathological contents of the Museum, one by Mr. V. Zachary Cope, one by Mr. R. J. McNeill Love, one by Mr. P. H. Mitchiner, two by Mr. L. W. Proger, and one, on the surgical manifestations of Boeck's sarcoid, by Mr. R. W. Raven.

*Arnott Demonstrators*.—Six demonstrations on the contents of the Museum, three each by Dr. R. J. Last and Mr. H. F. Lunn.

The eighteenth Macloghlin Scholarship was awarded to Alexander Livingston (Epsom College).

A Diploma of Fellowship was granted to Donald Patrick Robertson and a Diploma of Membership to Antony Josef Ruzicka.

Diplomas in Psychological Medicine, in Laryngology and Otolaryngology, and in Industrial Health were granted, jointly with the Royal College of Physicians of London, to the following successful candidates:

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—E. H. Cranswick, J. A. Crawford, P. B. de Maré, J. J. Fleminger, E. H. Hare, A. B. Hegarty, R. F. Hobson, J. G. Howells, W. Ironside, J. Johnston, G. N. Jones, V. L. Kahan, J. Katz, L. G. Kiloh, A. B. Kinier Wilson, C. C. Lack, A. F. McLean, M. Markowe, D. A. R. Pond, K. C. Royes, P. Sainsbury, A. B. Sclaire, S. Tischler, P. M. Turquet, A. H. Williams.

DIPLOMA IN LARYNGOLOGY AND OTOLARYNGOLOGY.—J. Ackerley, J. N. Appleton, L. F. Day, P. F. King, J. A. Langille, J. M. Marquard, Peggy K. L. Orton, C. C. Ring, R. V. Tracy-Forster, K. L. Wilson.

DIPLOMA IN INDUSTRIAL HEALTH.—W. E. Broughton, Caroline J. Brown, A. Butterworth, J. V. Manning, H. B. Melzer, Niaz-ud-Din, Dorothy Williams.

A Diploma in Anaesthetics was granted, jointly with the Royal College of Physicians of London, to N. C. Smiedt.

### SOCIETY OF APOTHECARIES OF LONDON

At a meeting of the Court of Assistants held on June 17 with Dr. C. Thackray Parsons, Master, in the chair, the report of the death, on June 19, of Dr. Cecil Wall, Father of the Court and Archivist to the Society, was received with profound regret.

The following representatives were appointed: Central Midwives Board, Dr. J. P. Hedley; British Postgraduate Medical School Governing Body, Sir Cecil Wakeley; Central Council for District Nursing, Mr. George Wynn-Williams, in succession to Dr. Douglas Kirkwood, resigned; XIth International Congress of Pure and Applied Chemistry, Prof. E. C. Dodds, F.R.S., and Dr. G. Roche Lynch; Commission Internationale Permanente pour la Médecine du Travail, Dr. Thackray Parsons.

The reports of the representatives on the General Medical Council and the Negotiating Committee were received.

The Honorary Freedom of the Society was bestowed upon S. Stanley Hewett, Surgeon-Apothecary to the King.

P. W. Monckton Copeman was bound apprentice to W. S. Copeman for four years.

The Mastery of Midwifery, *honoris causa*, was conferred upon Sir Allen Daley, Sir Eardley Holland, and Sir William Fletcher Shaw.

The report of the death, on May 16, of Sir Frederick Gowland Hopkins, Gold Medallist, was received with great regret.

It was decided that a course of eighteen subscription lectures on modern therapeutics be delivered in the Hall during October and November, 1947.

The Diploma in Industrial Health was granted by examination to A. Bell.

The Diploma of L.M.S.S.A. was granted upon examination to the following candidates: J. A. Archer-Hall, M. G. Allen-Mersh, A. C. Lewis, G. R. Hollings, R. P. K. Sen, R. D. C. Hart, P. Sattin, F. W. P. Clutterbuck, A. R. Ellerker, J. S. Lambe.

### SCOTTISH CONJOINT BOARD

The following candidates, having passed the final examination, were admitted L.R.C.P.Ed., L.R.C.S.Ed., and L.R.F.P.&S.Glas., on July 18: D. K. M. Allison, W. B. Balderston, Mary E. Barton, R. Black, J. F. Chacko, J. T. N. Cole, J. Crow, T. L. C. Dale, W. Davidson, Maureen M. Devine, D. C. Drummond, C. G. Duncan, Sheila M. Forsyth, S. Goldin, S. H. Goodman, D. S. Griffith, G. F. V. Hossack, Matilda Y. D. Hutchison, W. Jack, L. Kramer, A. Laidlaw, D. M. Lyon, K. I. MacLean, H. McNeill, B. MacTaggart, Mary A. Mahoney, A. Millar, D. L. Moody, Janet Q. Morton, M. C. Penny, W. R. Plews, Doreen S. Ryan, Doreen R. C. Scorgi, A. W. R. Thom, N. Weiselberg, Margaret L. Westwater.

### COMBINED HOSPITALS UNIVERSITY ENTRANCE SCHOLARSHIPS

The following awards have been made:

*St. Bartholomew's Hospital Medical College*: Jane Swithinbank, Newnham College, Cambridge (Scholarship).

*Guy's Hospital Medical School*: W. G. Rhys-Jones, St. John College, Oxford (Scholarship); D. J. Müller, Oriel College, Oxford (Exhibition).

## Towards MORE NORMAL CONTROL

Successful control of diabetes cannot be claimed unless the blood sugar is kept within safe limits and the patient's activities are interfered with as little as possible. One injection of Globin Insulin (with Zinc) before breakfast is no great inconvenience and can control the blood sugar throughout the twenty-four hours in the majority of mild and moderately severe diabetics. Globin Insulin is a further step towards the ideal—the normal control of blood sugar.

**'WELLCOME' GLOBIN INSULIN (WITH ZINC)**  
40 and 80 units per c.c., each strength in phials of 5 c.c.

## 'THIAZAMIDE'

BRAND

### Sulphathiazole

Sulphathiazole is one of the most active sulphonamides at present available for the treatment of pneumococcal, meningococcal, gonococcal and haemolytic streptococcal infections—the sulphonamide of choice for the treatment of urinary tract infection, staphylococcal infections and gas gangrene; an effective chemotherapeutic agent in acute bacillary dysentery and in chancroid.

'SOLUTHIAZOLE' brand neutral soluble sulphathiazole derivative is recommended when parenteral administration is indicated.

May & Baker's sulphathiazole preparations are protected by British Patent No. 533,495, which was granted on 24 May, 1946, jointly to May & Baker, Ltd., and Ciba, Ltd., of Basle.

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD., DAGENHAM

## A Development in Salicylate Therapy

'ALASIL' presents the beneficial therapeutic effects of acetyl-salicylic acid in such a form that it is readily acceptable even to patients with finely balanced digestive systems. This high tolerability is due to the fact that 'Alasil' combines acetylsalicylic acid with Dibasic Calcium Phosphate and 'Alocol' (Colloidal Hydroxide of Aluminium), a potent gastric sedative and antacid.

For this reason 'Alasil' can be administered with confidence in all the conditions in which such an agent is indicated, while its use affords the advantage of greater freedom from the possibility of unpleasant gastrointestinal sequelae.

'Alasil' is, therefore, an analgesic, antipyretic and antirheumatic which can be prescribed for patients of all ages. Moreover, it is so well tolerated that its use can be continued to the desired extent.

# Alasil

TABLETS

A supply for clinical trial with full descriptive literature sent free on request

A. Wander  
Ltd.  
London  
S.W.7  
M 324

Each tablet contains 5 grs. Acetyl-salicylic Acid, 6 grs. 'Alocol' (Colloidal Hydroxide of Aluminium), and 1½ grs. Dibasic Calcium Phosphate.

## PROGRESS and the B<sub>2</sub> VITAMINS

Views on the singleness of vitamin B have had to undergo considerable revision since the early days of the discovery of vitamins. The original recognition of a single water soluble B vitamin, and further division into vitamins B<sub>1</sub> and B<sub>2</sub>, has been followed by the identification of many other constituents which are now known to form part of the vitamin B<sub>2</sub> complex.

As further progress is still to be expected it is often considered preferable to administer a natural source of the B<sub>2</sub> vitamins, such as Marmite, where all factors appear to be present in balanced proportions—those already isolated as well as those which still remain to be differentiated.

# MARMITE

yeast extract

contains

Riboflavin (vitamin B<sub>2</sub>) 1.5 mg. per oz.  
Nicotin (nicotinic acid) 16.5 mg. per oz.

Jars: 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9  
Obtainable from Chemists and Grocers

## PENICILLIN LOZENGE B.P.

### For Oral and Throat Infections

Designed for slow disintegration when sucked in the mouth, 'Avlon' Penicillin Lozenges provide a convenient, pleasant and effective means of maintaining bacteriostatic concentrations of penicillin in the saliva.

Indicated in the prophylaxis and treatment of infections of the mouth and throat, the lozenges have proved highly effective in ulcerative conditions of the oral mucous membrane, e.g., Vincent's angina and in pharyngitis, sore throat and laryngitis. 'Avlon' Penicillin Lozenges each contain 500 international units of penicillin calcium salt and are issued in convenient air-tight containers of 25.

Obtainable from your usual suppliers.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 5.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of:  
(a) The 126 great towns in England and Wales (London included),  
(b) London (administrative county),  
(c) The 13 principal towns in Eire, (d) The 10 principal towns in Northern Ireland.

A dash—denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Smallpox

No further cases have been reported in England and Wales during the past week up to July 22.

At Willenhall U.D. the patient removed on July 9 was confined to bed from the onset. Contacts are limited to members of the household, all of whom are under surveillance. At Bilston Borough the period of surveillance of contacts has now expired without further cases being detected. The last patients at Barnsley C.B., both removed on July 11, are suffering from discrete rashes modified by vaccination seven and nine days before onset. Contacts are still under surveillance, but the position is not unsatisfactory.

## Poliomyelitis

In the week ending July 12 there were 110 notifications of acute poliomyelitis and 16 of acute polio-encephalitis in England and Wales. These are the highest weekly figures since universal compulsory notification was instituted. Notifications were widely scattered, being received from 82 extra-Metropolitan sanitary districts and 11 Metropolitan boroughs. Outside the administrative County of London multiple cases (of poliomyelitis and/or polio-encephalitis) were recorded in Wareham and Purbeck R.D. 8, Houghton-le-Spring U.D. 2, Spennymoor U.D. 3, Watford R.D. 4, Stock C.B. 2, Brighton C.B. 2, Sutton Coldfield M.B. 3, Hull C.B. 2, Bradford C.B. 4, Dewsbury C.B. 2, Sheffield C.B. 2, Shipley U.D. 2, Spennorth U.D. 2.

The main feature in the epidemiology is the multiplicity of foci, with occasional evidence of concentric spread. The latter is particularly obvious in the South-East and South of London. Twenty-seven cases have been removed from Lewisham to L.C.C. hospitals since July 1. The total admissions of suspected poliomyelitis and polio-encephalitis to L.C.C. hospitals have been 65 during the same period. At present there are 50 cases under treatment in these hospitals.

It appears that the number of cases exhibiting signs and symptoms which are predominantly cerebral is still larger than in any previous experience of the disease in this country. The number of cases notified as polio-encephalitis (16) is higher than any weekly total previously recorded. The question whether these cases are due to the same virus as poliomyelitis or to some other cause is not yet settled, but poliomyelitis is the most probable diagnosis in patients showing meningeal reaction. (Attention is drawn to the memorandum which appears on page 141 of this issue in which the steps being taken to investigate this point are described.)

## Botulism

On June 6 five persons who took lunch at a small teashop in the London area on the previous day noticed abdominal discomfort followed by obstinate constipation. Two of them vomited and all subsequently developed difficulty with vision, and/or speech and swallowing. One man died on the twelfth day; necropsy confirmed that death was due to botulism. Two remained ambulant throughout. It is not improbable that several, perhaps half a dozen, other persons were involved. An annotation at p. 138 of this issue of the *Journal* draws attention to the signs and symptoms of the disease. If suspicious cases are known, the attention of medical officers of health should be drawn to them.

## Food-poisoning

Inquiries into the outbreak of food-poisoning at Lincoln, where salami sausage served at a hotel meal on July 5 caused 34 cases of infection with *Salmonella typhi-murium*, have shown that a member of the hotel staff who handled the sausage gave a history of diarrhoea on July 4-5. His faeces have now been proved positive for *Salmonella typhi-murium*. In most cases the onset was severe and within a few hours; all showed symptoms within 24 hours. The majority became very ill, with vomiting, severe diarrhoea, and high temperature, and some fainted. As reported last week (July 19, p. 117), there was one death.

## Discussion of Table

In England and Wales infectious diseases were more prevalent during the week, the increased notifications including measles 892, whooping-cough 188, acute poliomyelitis 23, scarlet fever 19.

Only small fluctuations occurred in the local returns of scarlet fever and acute pneumonia. The increase in whooping-cough occurred mainly in two counties—London 99 and Lancashire 74. There was in general a greater incidence of measles cases, the largest increases being Glamorganshire 122, and London 117, while opposed to this trend were the decreases

in Gloucestershire 105 and Cambridgeshire 103. The chief feature of the returns for diphtheria was a decreased incidence of 12 in Lancashire.

Only two cases of dysentery were notified in Surrey compared with 28 in the preceding week. An outbreak of typhoid in Suffolk, Thedwastre R.D., was responsible for 9 of the 15 cases notified during the week.

For the fifth consecutive week an increase has been reported in the notifications of acute poliomyelitis; the 79 cases occurred in 24 counties, the largest focus of infection during the week being Leeds C.B. 7.

In Scotland there were increased notifications of scarlet fever 16 and dysentery 12, while decreases were recorded for measles 36, whooping-cough 34, and diphtheria 10. The largest returns for dysentery were Edinburgh 10. The rise in scarlet fever was general in the western area.

In Eire a decrease of 16 was recorded in the notifications of diphtheria, while increases were recorded for measles 44, whooping-cough 31, and scarlet fever 22. Diarrhoea and enteritis, 54 cases, remained at the high level of the preceding week. The rise in measles and whooping-cough was mainly contributed by Dublin C.B. The chief centres of scarlet fever were Limerick C.B. and Galway U.D.

In Northern Ireland a rise occurred in the notifications of diphtheria 10 and typhoid fever 10. Seven of the 15 cases of diphtheria were notified in Belfast C.B. Eleven further cases of typhoid were reported from the outbreak in Belfast C.B., where 7 cases were reported last week.

#### Week Ending July 12

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 918, whooping-cough 2,000, diphtheria 181, measles 9,133, acute pneumonia 332, cerebrospinal fever 67, acute poliomyelitis 110, dysentery 50, smallpox 3, paratyphoid 8, typhoid 12.

## Medical News

### The Berkeley Fellowship

Applications from graduates in medicine of the Middlesex Hospital Medical School are invited for the Berkeley Fellowship. Candidates should be under 35 years of age. The salary is £600 per annum, with certain extra allowances for travelling and research. The Fellowship is tenable normally for one year, but applications for renewal will be considered. Applications should reach the Dean of the Middlesex Hospital Medical School by Sept. 1. A broad outline of the programme of work or proposed itinerary, together with an estimate of cost, should be submitted with the application. The Berkeley Fellowship was founded under the will of the late Sir G. H. A. Comyns Berkeley to provide research and travel facilities to a person elected jointly by the Master and Fellows of Gonville and Caius College, Cambridge, and the Council of the Middlesex Hospital Medical School. Under the terms of the bequest medical centres in any part of the world may be visited with the exception of Oxford or Cambridge.

### Memorial to Sir Hubert Bond

A tablet erected by his widow to the memory of the late Sir Hubert Bond has been erected in the chapel at Long Grove Hospital, Epsom, Surrey, and will be unveiled during evensong on July 27, by Sir Allen Daley. The service begins at 5.30 p.m. An invitation to be present is extended to Sir Hubert's colleagues and friends. A convenient train from London leaves Waterloo at 4.42 p.m. and is due at Epsom at 5.11 p.m. Transport will be provided between Epsom station and Long Grove Hospital.

### British Journal of Cancer

We welcome the appearance of a new quarterly journal under the above title. It is edited by Prof. R. W. Scarff, who is assisted by Dr. F. R. Selbie and a board of advisory editors whose names are familiar to those interested in cancer research. The new journal is published by H. K. Lewis and Co., of 136, Gower Street, London, W.C.1. The annual subscription is two guineas and single copies are priced at 12s. 6d. each. There are twelve articles in the first number, the first of which is a paper entitled "Applications of Recent Advances in Nuclear Physics to Cancer Research" by Dr. J. S. Mitchell, Professor of Radiotherapeutics at Cambridge. An interesting feature of this journal is the printing at the end of brief summaries of the articles under the heading "Survey of Papers." This is a variation of the practice of some journals which print such summaries at the head of each article. *The British Journal of Cancer* is a notable addition to scientific medical periodicals, and the excellent start it has made is a promise of good things to come.

### Honorary C.B.E.

Dr. Philip D. Wilson, surgeon-in-chief, Hospital for Special Surgery, New York, and clinical professor of orthopaedic surgery, College of Physicians and Surgeons, Columbia University, who organized and brought over the American Hospital in Britain in 1940, has been appointed Honorary C.B.E.

### Elected F.R.S.Ed.

The following medical men have been elected to Honorary Fellowship of the Royal Society of Edinburgh: Sir Alexander Fleming, Sir Arthur MacNalty, Prof. Alfred N. Richards (U.S.A.), and Prof. Albert de Szent-Györgyi (Budapest).

### Nine Scottish Nurses

The first nursing qualifications to be bestowed by a Scottish university were received by nine nurses at Edinburgh University Graduation Ceremony on July 16. They are the first holders of the University's Sister Tutors' Certificate. The standards set were agreed upon by a committee of the University and the Royal College of Nursing.

### The Future of Spas

The British Spas Federation announces that every spa is preparing a plan, for submission to Regional Hospital Boards, on how facilities for treatment at the spa, including those at rheumatism hospitals, general hospitals, and other establishments, might be used in a regional scheme for the treatment of rheumatic, orthopaedic, and post-operative conditions.

### Belgian Gratitude to Britain

The Belgian Government and people are giving three weeks' holiday in Belgium in August to 500 British children aged 12 to 14. The Save the Children Fund is organizing the party.

### Visitors from Egypt

Dr. Mohammed Razzak, Principal Medical Officer for Child Welfare at Cairo, and Dr. Ibrahim Yusuf, of the Ministry of Public Health at Cairo, are visiting Britain under the auspices of the British Council. Dr. Razzak attended the bicentenary conference at the Rotunda Hospital in Dublin, from which he graduated in 1933; he will tour child welfare and maternity centres in Britain. Dr. Yusuf is studying the management and equipment of hospitals in this country and also the plans for nationalization.

### Wills

The Rev. Dr. William Osborne Greenwood, F.R.S., of Harrogate, who died on Jan. 8, left £340. Dr. William Gloag Galletly, of Anerley, London, S.E., who died on Feb. 23, left £32,536. Dr. Frederic Samuel Barber, of Upper Norwood, S.E., who died on March 15, left £5,291. Dr. Reginald Mark Moore, of Marnhull, Dorset, formerly Medical Officer of Health for Malmesbury, who died on Jan. 26, left £24,358. Lieut.-Col. Henry James Wyatt, R.A.M.C. (retd.), of Weybridge, Surrey, who died on Feb. 12, left £31,576. He left, among other bequests, the proceeds of sale of certain shares to the N.S.P.C.C. and the Royal Masonic Benevolent Institution. Dr. Charles Mowbray Pearson, of Newbridge, Midlothian, who died on Jan. 23, left personal estate in England and Scotland valued at £78,544. Dr. Henry Canwarden, of Guildford, Surrey, who died on April 20, left £1,422. Dr. Harold Augustus Easton, of Worthing, formerly of Thornton Heath, who died on April 2, left £3,530.

## COMING EVENTS

### Mental Health

An International Congress on Mental Health will be held at Central Hall, Westminster, S.W., from Aug. 12 to 21, 1948, and will consist of three conferences: Aug. 12 to 15, morning sessions, international conference on child psychiatry, under the auspices of the International Committee for Child Psychiatry to discuss "Foundations of Mental Health in Childhood"; Aug. 12 to 15, afternoon sessions, international conference on medical psychotherapy, under the auspices of the International Federation for Medical Psychotherapy, to consider "Guilt"; and Aug. 16 to 21, mornings and afternoons, international conference on mental hygiene, under the auspices of the International Committee for Mental Hygiene with its incorporated and allied bodies, at which "Mental Health and World Citizenship" will be discussed. The chairman of the organizing committee of the congress is Dr. J. R. Rees, C.B.E., F.R.C.P., and full particulars can be obtained from the Organizer, International Congress on Mental Health, 39, Queen Anne Street, London, W.1.

### Population

The U.N. Population Commission will meet at Lake Success, N.Y., on Aug. 18.

**Prostitution**

The International Abolitionist Federation are holding a congress at Brussels on Sept. 6-9 on "Present-day Aspects of the Regulation of Prostitution." Subjects to be discussed include regulation by public authorities, compulsory treatment of venereal diseases, the administrative internment of persons said to be asocial, and the part played by men in prostitution. Those in Britain willing to take part in these discussions should register before Aug. 1 with Miss Hardwick, Association for Moral and Social Hygiene, Livingstone House, Broadway, London, S.W.1 (charge 6s.).

**W.H.O.**

The International Commission of the World Health Organization will meet for its fourth session on Aug. 30.

**Industrial Design**

The Scottish Committee of the Council of Industrial Design will hold an exhibition of industrial design in the Royal Scottish Museum, Edinburgh, in August and September, opening on Aug. 25. A special feature of the exhibition will be a section arranged by the Department of Health for Scotland, and there will be exhibits from Scottish firms manufacturing scientific instruments.

**Blood**

The second International Haematology and Rh Conference will probably be held in 1948.

**SOCIETIES AND LECTURES**

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Thursday, July 31, 6.15 p.m. Hunterian Lecture by Prof. H. W. Rodgers: Late Result of Gunshot Wound of Abdomen.

**ROYAL SOCIETY OF MEDICINE**

Section of *Orthopaedics*.—Tuesday, July 29, 8.30 p.m. Paper (illustrated by a film) by Dr. H. H. Kessler (Newark, New Jersey): *Cineplastic Amputations*. Members of the Sections of Physical Medicine and Surgery are specially invited to attend.

**POSTGRADUATE DIARY**

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, W.C.—Wednesday, July 30, 4.30 p.m. Mr. V. E. Negus: The Larynx.

**APPOINTMENTS**

The Secretary of State for Scotland has appointed Mr. H. W. Guthrie, K.C., to be chairman of the Scottish Nurses Salaries Committee in succession to Mr. John Wheatley, K.C.

Dr. Marcus M'Calley has been appointed radiological consultant for the English Southern Counties.

Dr. Ernest H. Capel, of Birmingham, has been appointed Chief Medical Officer of the National Coal Board.

Dr. Capel, who is 40, received his medical training at the Middlesex Hospital, proceeding M.D. in 1933. He is a member of the Advisory Medical Committee of the Industrial Welfare Society, and until recently was Secretary of the Birmingham Group of the Association of Industrial Medical Officers.

BOWEN, RONALD A., M.B., D.A., Assistant Administrator of Anaesthetics, St. Bartholomew's Hospital, London, E.C.

GRETTON-WATSON, B. G., M.B., B.Chir., D.P.H., Deputy Medical Officer of Health and Deputy School Medical Officer, County Borough of Dudley.

**BIRTHS, MARRIAGES, AND DEATHS**

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

**BIRTH**

REED.—On June 27, 1947, at Oaklands Nursing Home, St. Leonards-on-Sea, to Susan, wife of Dr. B. C. M. Reed, a son.

**MARRIAGE**

LUSH-GEE.—At Hutton, Essex, on July 12, Dr. Brandon Lush to Dr. Margaret Gee.

**DEATHS**

KERRY.—On June 25, at the Radcliffe Infirmary, Theo R. F. Kerby, M.R.C.S., L.R.C.P., D.M.R.E., aged 52, dear husband of Mary Kerby, Redesdale, Brackley.

MORISON.—On July 16, suddenly, at 28, Forty Lane, Wembley, Alexander Gavin Morison, M.A., M.D., D.P.H., Medical Officer of Health, Wembley, aged 54.

WOODRUFF.—On July 14, 1947, suddenly at Telwerth, Surbiton, David Winthrop Woodruff, L.R.C.P., L.R.C.S., aged 62.

**Any Questions?**

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

**Bleached Bread with Added Chalk**

**Q.**—Is the substance used for bleaching bread, and the excessive amount of chalk in it, prejudicial to health?

**A.**—Sir Edward Mellanby has recently claimed (*B.M.J.*, 1946, 2, 885) that the treatment of flour with nitrogen trichloride (the agene process) produces toxic compounds which cause canine distemper. The connexion with canine distemper has been disputed. Sir Edward gives a disturbing list of substances used as bleachers and "improvers." Even if the bleaching processes are harmless, this pointless monkeying with important foods seems most reprehensible.

The addition of chalk to flour is an entirely different matter. Chalk is an inert substance. The amount added is not excessive. The total amount of calcium supplied per day by the flour of a normal consumer is not more than 220 mg., which is about one-third of the average day's intake of calcium and equal to the amount in one-third of a pint of milk. There is no evidence that intakes of calcium salt of the order of 1 g. or more are harmful.

**Solar Plexus Knockout**

**Q.**—What is the physiology of the knockout blow in the "solar plexus," with its temporary respiratory paralysis and the feeling of never being able to breathe again?

**A.**—The effects of a blow in the "solar plexus" are usually ascribed to afferent impulses set up in the visceral nerves by the blow. These reflexly cause inhibition of respiration, a slowing or stoppage of the heart, and a fall in blood pressure. In Goltz's classical experiment inhibition of the frog heart is caused by tapping the intestines.

**Escape of Semen**

**Q.**—What is the cause of the semen escaping from the vagina after normal intercourse?

**A.**—It is normal for a considerable proportion of the semen to escape from the vagina after coitus, but this tendency is exaggerated if the introitus is stretched and gaping as a result of childbearing and particularly if prolapse is present. A change in position immediately after coitus, especially standing and walking, also favours the escape of semen. Although many women have the idea that effluvium seminalis is the cause of sterility, it rarely, if ever, is important.

**Actinomycosis**

**Q.**—Are human beings who drink the milk from a cow suffering from the condition known as "lumpy jaw" in danger of contracting actinomycosis? Are sulphonamides of use in treatment in humans and in animals?

**A.**—Actinomycosis is a local disease and the organism is not present in the milk of diseased cows, so there is no danger of infection from drinking the milk. Sulphonamides certainly help to cure human actinomycosis, but mainly by combating secondary septic infections. Presumably the same would hold good in the case of animals. Some have found that sulphonamides seem to assist the action of penicillin, which, of course, is itself a powerful remedy for actinomycosis.

**Excretion of Citrate after Transfusion**

**Q.**—How is the 2% solution of disodium citrate in transfused blood excreted, and how is it estimated in the urine?

**A.**—The greater part of the citrate in transfused blood is converted into sodium bicarbonate: 30 to 40% is excreted in the urine as citrate. Methods for estimating citric acid are given by Pucher, Sherman, and Vickery (*J. biol. Chem.*, 1936, 113, 235) and by Krebs and Eggleston (*Biochem. J.*, 1944, 38, 426).

**Penicillin for Congenital Syphilis**

**Q.**—Is penicillin of value in the treatment of congenital syphilis? If so, what dose would you advise for a child of 4?

**A.**—Yes, penicillin is probably the most effective single therapeutic agent for congenital syphilis, but it would be wise to supplement it with arsenic and bismuth unless there is any contraindication; the total dose should be 100,000 units per kilogram of body weight. Penicillin may be in aqueous solution or in an oily base; in the former case injections should be given in equally divided doses every three hours over a period of about twelve days; in the latter once or twice daily is often enough.

**Judicial Hanging**

**Q.**—What is the length of the drop in a judicial hanging?

**A.**—On an average, six feet (1.8 metres), varying inversely with the weight of the body. The knot is placed at the angle of the jaw, and the object is to jerk the head sideways, fracture or dislocate the vertebral column, and rupture the spinal cord. This happens almost invariably, the dislocation usually occurring between the second and third cervical vertebrae. Although some other structures may be damaged, the strain is not nearly enough to divide the muscles and ligaments completely.

**Injection Treatment of Arthritis**

**Q.**—What are the most recent types of treatment by injection for arthritis other than (1) injecting the patient's own blood after exposure to ultra-violet rays, and (2) injecting lactic acid into the affected joints?

**A.**—The most recent methods of treatment by injection in arthritis, other than those mentioned, are (a) by sodium bismuth tartrate, which is inferior in its results to gold but may be useful where gold is not tolerated, and (b) the intravenous injection of organic salts of copper, which has been tried in France and for which good results have been claimed. Acid potassium phosphate has been used on the same lines as lactic acid but appears to have been supplanted by the latter.

**Leprosy Bacilli**

**Q.**—Can you tell me how leprosy bacilli react to heat, to antiseptics, and to sunshine? There seem to be no facts to go on except the probable similarity to tubercle bacilli.

**A.**—As is inferred in the question, there are no exact data on this subject, because leprosy bacilli cannot be cultivated; ordinary methods of determining susceptibility to heat, light, and disinfectants are therefore impracticable. Among the various *Mycobacteria* which can readily be cultivated there are no great differences in these properties, and it is reasonable to assume that leprosy bacilli react in very much the same way as tubercle bacilli.

**Methyl Testosterone for Hypogonadism**

**Q.**—Is methyl testosterone of value in the treatment of male hypogonadism? If so, for how long should it be given and in what dosage? What are the main toxic effects?

**A.**—Methyl testosterone is of value in hypogonadism and the dosage is usually one 5-mg. tablet by mouth three daily. It is most logically given in cases of primary hypogonadism, such as eunuchoidism or following traumatic castration. It is also of value in hypogonadism secondary to a pituitary deficiency—for example, Fröhlich's syndrome or infantilism—but initial treatment in these pituitary cases should be with gonadotrophic hormone, which, however, may require supplementing with testosterone or methyl testosterone. Although the latter substances stimulate the penis they have no stimulating effect on the gonads. Their general metabolic effect—for example, nitrogen retention and muscular development—is important, as also is their psychological effect. Treatment must be continued for some months and sometimes indefinitely as it is substitution therapy. There are no real toxic effects, but the psychological effects may be excessive in children or adolescents. In people with normal gonads large enough doses will cause involution and disorganization of the testicles.

**NOTES AND COMMENTS**

**Chronic Nasal Blush.**—Dr. A. F. WALSH (Collic, Western Australia) writes: In the hope that I may be able to help the patient whose doctor's query appeared under "Any Questions?" (May 24, p. 749) I would like to tell him of my own experience. Having been a sufferer myself I fully appreciate the embarrassment and humiliation of the patient. It seems as if the entire company is looking at one's nose—as indeed they do from time to time. The erythema of the nose is most marked when the mind is most active—i.e., when sweating hardest before exams, when hardest pressed in busy practice, or worrying over business affairs. In my case there was no complaint of indigestion, but I am convinced that an occult gastritis was present, and so I can now always control the attacks by adhering to a "maintenance ulcer type of diet" with plenty of milk, eggs, cream, butter, and fatty meat, etc., and also with the help of alkaline powder when the flush is threatening.

And now I would like to ask a question myself. Three months ago I enucleated a prostate from a patient aged 60 who was the complete picture of prostatic obstruction. Three weeks after the operation there was no passage of urine per urethram, so under G.A. I passed a large sound into the bladder. It required a good deal of force to pass the sound. Since then he has suffered from incontinence of urine for the last two months. He now wears a permanent rubber urinal, which is a great nuisance. I wrote to our leading urologist in W.A. asking his advice *re* a penile clamp. His reply was that he had never had to use one and had never seen a case of post-operative incontinence except in tabetic cases. I should add that the prostate was a small fibrous one and very difficult of enucleation. I would deeply appreciate your advice in this distressing matter.

**Chronic Bronchitis.**—Dr. TREVOR H. HOWELL (Purley, Surrey) writes: Under the heading "Any Questions?" (July 12, p. 81) I feel that your correspondent might expect more help on the problem of bronchitic asthma. In the elderly this is often a serious problem. It throws much strain on the heart and circulation, thus tending to shorten life. In certain cases the symptom of bronchial spasm seems to be a precursor of left heart failure with pulmonary oedema. As your correspondent says, ephedrine often loses its effect in advanced cases, so that an alternative is needed. My own experience has evolved three other methods of relief. As antispasmodics, "aminophylline" or "benadryl" are superior to ephedrine. For injection, "hyperdure" adrenaline can give relaxation for several hours, which is especially useful at night. Finally a course of diathermy to the chest—say twelve applications, starting at ten minutes and then gradually working up to half an hour—sometimes acts when everything else has failed.

**Fissured Lip.**—Dr. STANLEY ROBERTSON (Musselburgh) writes: Having had occasion to treat several such cases, perhaps my treatment may be of interest. I find most of these patients were edentulous, with the "bite" too close. This results in a deep sulcus at the angles of the mouth leading to retained moisture and fissures. The cause must be removed by "raising" the bite. For the local treatment I find "albuic dental cerate" an excellent preparation. This is water-soluble sulphacetamide in a neutral cerate base, and the preparation is supplied by all dental depots. A mere trace of the ointment on the sore leads to comfort and healing provided the real cause is removed. In passing may I suggest that no denture is free of sepsis?

**Pediculosis Capitis.**—Dr. MICHAEL C. PLATTEN (Birmingham) writes: The details of the patient with pediculosis capitis who did not respond to repeated applications of medicated kerosene ("Any Questions?" July 12, p. 82) suggest that the diagnosis is at fault. I have quite frequently seen pityriasis capitis confused with pediculosis capitis, and it may be that that is the case here.

**Hair Turning White Overnight.**—Mr. R. J. McNEILL LOVE (London, W.1) writes: Following a narrow escape from a flying bomb, the hair of a patient of mine actually turned white in the night, as witnessed by me. What is the physiological or pathological explanation? I can get no satisfactory answer from my dermatological friends.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attilology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads, Westcent, London*.

GERDA SEIDELIN WEGENER  
*Copenhagen*

The study of medicine in Denmark is conducted at the State-owned Universities of Copenhagen (dating from 1537) and Aarhus (from 1926). Every year some 325 students begin their studies, while 30-40% fail for some reason or other to complete the course. The official curriculum takes seven years, but the average time is slightly above eight years, so that most candidates have reached the age of 26 before they qualify.

#### University Curriculum

The student enters the university at the age of 18. During the first two terms—i.e., for one year—he attends lectures and practical classes in inorganic and organic chemistry and in physics, at the end of which he takes his first professional examination. This preparatory examination roughly corresponds to the British first M.B. During this first year the student must also go through a course in philosophy, including psychology, ending with an examination. The course of study for the second M.B. extends over four terms (two years) and comprises human anatomy (including histology and embryology), physiology, and biochemistry. There are lectures and oral examinations as well as practical courses in dissection and microscopical anatomy, and laboratory courses in physiology and biochemistry. As material for dissection is scarce, much of the instruction rests upon museum preparations. Excellent modern institutes and spacious auditoria are available for this technical work. British textbooks of anatomy, such as Cunningham's and Gray's, are in use. The second M.B. is much feared on account of the wide range of factual and detailed knowledge required, especially in anatomy. Though private coaching is common, 40-50% fail at the first attempt (the candidate is allowed two). Plans for the introduction of theoretical papers on much the same lines as in Britain are under consideration.

Clinical work normally lasts eight terms (four years). The student serves three months as junior surgical dresser, two months as junior medical ward clerk, one month as junior at the post-mortem room; three months as senior surgical dresser, three months as senior medical ward clerk, and one month as junior ward clerk at a psychiatric department. The junior part of the course must immediately follow the second M.B. and the student is directed to particular hospitals by the medical faculty; time and choice of hospital departments for the senior part are left to the student's preference (which is often for provincial hospitals). Two months must be spent in out-patient departments. During the clinical training period the student attends preliminary courses given by hospital assistants, as well as a practical laboratory course in bacteriology, and lectures in genetics and hereditary diseases.

The official university hospital of Copenhagen is the State-owned Rigshospital, containing departments for all the special-

ties necessary in medical education. The Rigshospital, dating from 1910, is inadequate and old-fashioned, and plans for its modernization are under consideration. At Aarhus University the new municipal hospital serves as university clinic, though a few specialties are not represented; as yet only the first five years of medical study can be undertaken here, after which the students complete their course in Copenhagen.

#### Extraordinary Clinical Professorships

In order to utilize the clinical material of other hospitals and to make clinical education more effective, the chiefs of certain hospital departments outside the university hospitals in Copenhagen and Aarhus are appointed extraordinary professors. In Copenhagen, where this system has been adopted for several years, there are at present four extraordinary professorships in each of the subjects of clinical medicine and surgery, and one in each of the subjects of paediatrics, dermatology, ophthalmology, and otolaryngology. Here the students get extra clinical courses in small teams. This increase in the number of teachers has become very necessary because the university professors and assistants are comparatively few. In the theoretical subjects a professor with two or three assistants has to teach three or four hundred students at a time.

Theoretical and clinical lectures and demonstrations are attended during the whole clinical part of the study. These are not obligatory, since the characteristic feature of Danish medical study is that it is considered as a free study rather than a school task. So-called "clinics," where a student examines one of the in-patients and reads his case report to the professor and class for subsequent discussion, constitute the principal means of clinical teaching.

The second term comprises a class in clinical medicine and in paediatrics; the third, lectures in neurology and in psychiatry, a clinical course in skin and venereal diseases, concluded by an examination (either passed or not, no marks being given), and a class in clinical surgery; the fourth term, lectures in radiology, clinical courses in ophthalmology and in oto-rhino-laryngology (with examination as above), and a clinical course in fevers. The fifth and sixth terms comprise lectures and practical courses in pathology, bacteriology, pharmacology, and hygiene. Then follow oral examinations (third M.B.) in the subjects mentioned, and a six-hour paper in hygiene. The seventh and eighth terms are devoted to the final clinical study, including lectures in obstetrics, gynaecology, and forensic medicine. Practical courses in pelvic examination and contraception, together with one week's "living-in" at the University Maternity Clinic, are obligatory, but there is no service corresponding to the British "obstetric dresser." Practical operative exercises on cadavers, which played a considerable part in the past, have been cancelled owing to lack of material.

The final examination (second part of third M.B.) comprises oral examinations in theoretical and clinical medicine and surgery, clinical examination in paediatrics, oral examination in obstetrics and gynaecology and in forensic medicine, together with six-hour papers in medicine and surgery. The successful student then receives the degree of "candidatus medicinae et chirurgiae" (M.B., B.S.). To ensure further hospital training, six months in a surgical ward as a junior house-surgeon, and five months in a medical ward as junior house-physician, together with one month's duty at a maternity hospital, have been made compulsory. In this comparatively

Notes.—(i) The Association has undertaken to guarantee £100,000 to a special fund which has been established for the furtherance of the interests of the medical profession in connexion with the National Health Service Act.

(ii) The accounts of the subsidiary company, the Scholastic, Clerical, and Medical Association, are separately kept and audited. The dividends received have been brought into account under Interest on Investments; the remainder of the profits of that Company have been carried forward in its own accounts. In respect of the year ended March 31, 1946, the remuneration payable by the above-named Association to those of its Directors who were also Members of the Council of the British Medical Association amounted to £536 11s. 10d.

## AUDITORS' REPORT TO MEMBERS OF THE ASSOCIATION

Having examined the Balance Sheet, dated December 31, 1946, and Accounts with the Books and Vouchers of the Association except as regards the Scottish Committee Accounts, which have been audited by Messrs. Kennedy, Smillie & Co., and having received all the information and explanations we have required, we report that the Balance Sheet is, in our opinion, properly drawn up so as to exhibit a true and correct view of the state of the affairs of the Association according to the best of our information and the explanations given to us and as shown by the Books of the Association.

We have inspected the Leases of the New Buildings, the proposals for Building Leases on sites of 13, 14, 15, 16, and 17, Tavistock Square and 18, Burton Street, and the Disposition in favour of the Association of the premises 6 and 7, Drumsheugh Gardens, Edinburgh, and have verified the investments of the Association on General Account, on account of the Trust Funds and of the Office Staff Superannuation Fund.

We further report that we have examined the Accounts with the Books and Vouchers, of the above Medical Funds administered by the Association and found them correct.

PRICE, WATERHOUSE & Co., 5, Frederick's Place, Old Jewry, E.C.2,  
Chartered Accountants.

July 10, 1947.

## SCOTTISH REGIONAL HOSPITAL BOARDS

## CHAIRMEN

The Secretary of State for Scotland has announced that the Chairmen of the Scottish Regional Hospital Boards are as follows: Northern Region, Mr. Donald Macpherson; North-eastern Region, Mrs. May Baird; Eastern Region, Mr. William Hughes; South-eastern Region, Dr. J. R. Greenlees, D.S.O.; Western Region, Prof. E. P. Cathcart, C.B.E.

## Correspondence

## "Doctor" Sign on Cars

SIR.—Several of your correspondents have suggested that some sort of distinguishing badge or notice should be prominently displayed on every medical practitioner's car to enable the passing doctor to be easily recognizable in case of emergency. However, no doctor remains permanently glued to the seat of his car, may I suggest that he bear the insignia of his profession on his person?—some sort of uniform, the details of which could vary in order to denote his specialty; and after the National Health Act has come into force "Bevan Boy" could be neatly inscribed on the lapel, preferably in luminous letters so that he could be easily recognizable after dark.—am, etc.,

A. F. ROBERTS.

## Superannuation

SIR.—Under the Draft Regulations recently published by I.M. Stationery Office the financial position of the older general practitioners does not appear to be very happy. For

example, a G.P. who happens to be over 65 on the appointed day and retires on his 70th birthday will have under five years' employment in the new Medical Service, and consequently he will not be entitled to a retiring allowance or a pension.

Is it not possible to permit this body of workers to opt to make payments which will allow a non-contributing period to reckon for pension as if it had been contributing service? This is to be permitted to members of the Federated Superannuation System for Universities and others. For example, a G.P. or other medical practitioner who joined the new Service at 65 and later found he was unable to continue until he was 75 might be given the opportunity to opt to pay a sum equal to what he would have paid if he had been able to continue for the full ten years of further active practice. This will entitle him to a quarter of his average remuneration for his last three years of practically contributing service as pension. In short this means "pay or work."

St. Helens, Lancs.

D. CAMPBELL.

## National Health Service

SIR.—Charles V, a King of France in the fourteenth century, paid the feudal lords for defending their own castles. "for," he said, "he that lets himself be paid ends by letting himself be commanded." This is just as true now as then.

If any medical men are so short-sighted as to permit payment on a salaried basis there is no question but that it will mean eventually Civil Service administration of a bureaucratic nature, and such administration will most certainly take steps to see that no medical man is allowed to draw in public money an annual amount equal to the salary of the highest civilian official of the department. That would be intolerable to a governing body. Time is drifting on, no doubt diplomatically, so that before any agreement or otherwise can be arrived at a State service will be launched as an accomplished fact.—I am, etc.,

St. Mary, Cornwall

B. H. SHAW.

## H.M. Forces Appointments

### ROYAL NAVY

Surgeon Commander V. F. Walsh to be Surgeon Captain.  
Temporary Surgeon Lieutenants N. M. Panton and J. K. Irving, R.N.V.R., have been transferred to the Royal Navy.

### ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commander G. F. Abererombie to be Surgeon Captain.  
Surgeon Lieutenant-Commander E. G. Brewis to be Surgeon Commander.

### ARMY

Colonel (Temporary Major-General) S. Arnott, C.B.E., D.S.O., late R.A.M.C., has relinquished the temporary rank of Major-General.

Colonel C. H. K. Smith, O.B.E., M.C., late R.A.M.C., having attained the age for retirement, has been retained on the Active List supernumerary.

Lieutenant-Colonel (local Brigadier) A. G. Harsant, O.B.E., from R.A.M.C., to be Colonel.

### ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel G. W. Will, O.B.E., has reverted to retired pay on ceasing to be employed and has been granted the honorary rank of Colonel. (Substituted for the notification in a *Supplement* to the *London Gazette* dated May 13.)

Lieutenant-Colonel T. Stanton has retired on retired pay and has been granted the honorary rank of Colonel.

Lieutenant-Colonel W. I. FitzG. Powell, having attained the age for retirement, is retained on the Active List supernumerary.

Majors T. J. Moloney and A. P. Trimble to be Lieutenant-Colonels.

Major L. C. Card has retired receiving a gratuity.  
*Specialist Short Service Commissions.*—War Substantive Captain A. O. McClay, from R.A.M.C., Emergency Commission, to be Captain. Lieutenant L. Mackie to be Captain. Lieutenant D. P. A. L. Scott, from Emergency Commission, to be Lieutenant.  
*Short Service Commissions.*—War Substantive Major D. H. Niblett, from I.M.S., I.A.M.C., Emergency Commission, to be Captain. Captains J. O. S. Anderson and P. C. Barry, from Emergency Commissions, to be Captains. Lieutenants W. G. L. Allan, W. Brodie, J. Carswell, D. A. Chadwick, I. W. Clark, D. S. Cranston, T. Dungavel, J. M. Hughes, J. Maclean, F. R. D. Minett, M. Redfern, H. Benson, N. C. Rees, I. Lamond, D. R. Patchett, and H. F. McElligott, from R.A.M.C., Emergency Commissions, to be Lieutenants.

### TERRITORIAL ARMY

#### ROYAL ARMY MEDICAL CORPS

War Substantive Captain J. A. Dudgeon, M.C., to be Captain.

### LAND FORCES: EMERGENCY COMMISSIONS

#### ROYAL ARMY MEDICAL CORPS

War Substantive Major B. G. Thompson has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

War Substantive Captains H. J. Hamburger and G. D. Rankin have relinquished their commissions and have been granted the honorary rank of Major.

War Substantive Captains E. G. H. Koenigsfeld, A. G. Kulkarni, E. K. Malone, A. A. Brockie, and D. M. Clement have relinquished their commissions and have been granted the honorary rank of Captain.

War Substantive Captains G. C. Hildrey and B. Messer have relinquished their commissions on account of disability and have been granted the honorary rank of Captain.

Lieutenant J. G. Roberts to be Lieutenant.  
To be Lieutenants: E. Anderson, H. C. Anton, B. Bernard, R. A. Chand, J. Cowie, L. Cudkowiec, W. R. Denny, J. H. Diggle, R. Earl, J. J. Flood, A. Folkson, J. M. Forbes, J. C. Foster, J. S. Gardiner, I. R. Haire, B. H. Hogben, D. H. Isaac, A. B. Jamieson, J. M. Livingston, D. O. Lloyd, E. Lyons, J. Millar, K. P. Milne, I. A. H. Munro, K. S. Murray, N. L. Paros, C. I. Phillips, J. M. Posada, B. F. Richards, J. F. S. Robertson, H. K. Rose, A. K. D. Rutherford, J. L. Ryan, R. A. Setchell, S. G. Siddle, N. H. Silverton, R. H. Shephard, D. S. Smith, J. Starkie, H. Stern, J. P. Stuart, D. W. Taylor, O. M. P. Tobias, S. Vakil, R. P. Vass, J. R. Wardley, R. A. L. Wenger, A. A. Weyman, J. White, G. Adam, C. W. Bowen, J. A. H. Brown, S. Cope, D. R. Cairns, R. D. Calcott, P. F. Daly, A. M. Davies, J. Dillon, S. C. Harper, P. J. D. Heaf, B. P. Hill, R. E. Jenkins, R. H. N. Lake, R. W. Lawrie, P. A. R. Lornie, A. C. Milne, J. L. Middlemiss, H. M. Park, D. A. Petrie, J. H. Raphael, J. L. Roden, J. A. Reynolds, M. L. Sacks, R. E. N. Tattersall, F. W. Thomas, M. J. Whelan.

### WOMEN'S FORCES

#### EMPLOYED WITH THE R.A.M.C.

War Substantive Captain E. Gilbertson has relinquished her commission on account of disability and has been granted the honorary rank of Captain.

War Substantive Captains E. Moffett, K. Krainer, and S. Donahue have relinquished their commissions and have been granted the honorary rank of Captain.

Lieutenant (Mrs.) Augustus G. Harrison to be Lieutenant.

*Specialist Short Service Emergency Commission.*—Frances J. Pounds to be Lieutenant.

To be Lieutenants: Nora M. Dwyer, Mary T. Keyes, Mavis H. Swift, Eileen M. K. Irwin, Mary A. C. MacHugh, Sheila M. Dineen, Alice Faulkner, Elizabeth M. Hargreaves, Edith Winternitz, Mary Staunton, Bridget B. Noone, Elsie M. Terry, and Bridget Cregan.

### INDIAN MEDICAL SERVICE

Major-General W. R. Stewart, C.B., C.I.E., hns retired.  
Colonel J. W. Vanreen, O.B.E., has retired and has been granted the honorary rank of Brigadier.

Colonels R. Lee, R. N. Khosla, O.B.E., and J. L. D. Yule have retired.

Lieutenant-Colonels J. W. F. Albuquerque, O.B.E., and A. V. Lopes to be Colonels.

Lieutenant-Colonel M. M. Cruickshank, C.I.E., has retired and has been granted the honorary rank of Colonel.

Lieutenant-Colonels Hari Das, P. M. Antia, R. A. Wartens, and G. V. Ram Mohan have retired.

Majors W. F. Cooper, A. N. Duggal, A. K. M. Khan, S. S. Bhatnagar, B. Chandhuri, O.B.E., H. L. Batra, A. V. O'Brien, L. Dass, S. M. K. Mallick, T. C. Puri, C. Mani, S. T. Davies, H. W. Farrell, O.B.E., B. D. Khurand, and R. R. Bakhshi to be Lieutenant-Colonels.

Major W. B. Roantree has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

Major C. F. J. Cropper, O.B.E., has retired and has been granted the honorary rank of Lieutenant-Colonel.

Captain J. Aitken has retired on account of ill-health and has been granted the honorary rank of Major.

Captain A. R. Woodforde has retired, receiving a gratuity, and has been granted the honorary rank of Major.

Captains A. D. Iliff, G. F. J. Thomas, J. H. Cater, R. D. Ewing, O. Walker, G. B. Jackson, C.B.E., C. W. Greene, W. L. Fennell, O.B.E., T. A. Cunningham, D. S. Piper, J. W. Lusk, M. D. Black, I. D. Sutherland, R. Passmore, G. J. H. Maud, T. P. Binns, and D. R. Hanbury to be Majors.

## Association Notices

### Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

(1) The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

(2) Any member of the Association who is engaged in general practice is eligible to compete for the prize.

(3) The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not therefore be omitted when it bears directly on results, their interpretations, and their conclusions.

(4) Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual General Meeting of the Association to be held in 1948.

(5) No study or essay that has been published in the medical Press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prize-winner in any year is not eligible for a second award of the prize.

(6) If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay, the decision of the Council on any such point shall be final.

(7) Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

(8) The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

(9) Inquiries relative to the prize should be addressed to the Secretary.

## LIVER FUNCTION TESTS IN THE DIAGNOSIS OF JAUNDICE

A REVIEW OF 200 CASES

BY

N. F. MACLAGAN, M.D., D.Sc., M.R.C.P., F.R.I.C.

(From the Department of Chemical Pathology, Westminster Hospital Medical School, London)

It is now generally agreed that no one liver function test will give a satisfactory picture of the activities of an organ which has so many metabolic tasks to perform, and the present tendency, particularly in the United States, is to use a battery of tests in every case of suspected liver dysfunction. Thus Watson (1944) advocates eleven tests for jaundiced and seven for non-jaundiced patients; other workers have used similar combinations (Mateer *et al.*, 1942; Neeffe and Reinhold, 1946).

In this country few hospital laboratories have had the technical assistance required to follow these suggestions on any worth-while scale, and this has led to a rather conservative devotion to older tests such as the van den Bergh reaction, which has only a limited value in the differential diagnosis of jaundice. Thus while recent quantitative modifications of this test are certainly useful in distinguishing between retention and regurgitation jaundice (Watson, 1946; Gray, 1947), the older claims to distinguish toxic from obstructive jaundice by this means have been abandoned by experienced clinicians and pathologists. A recent report by Sherlock (1946) indicates that similar objections apply to the serum protein and cholesterol estimations and to the intravenous galactose tolerance and hippuric acid tests. Unfortunately this latter distinction—obstruction versus hepatitis—is a much more frequent diagnostic problem in jaundiced patients.

The present communication is concerned with two types of test—the serum alkaline phosphatase estimation and certain flocculation tests—which have been the subject of previous reports (MacLagan, 1944a, 1944b, 1944c, 1945). Although somewhat empirical in nature these tests have the advantage of technical simplicity and of being applicable to a single blood specimen. The combination has proved of particular value in distinguishing obstructive from non-obstructive jaundice, no doubt because the phosphatase shows a maximum deviation from normal in obstructive jaundice while the flocculation tests show maximum abnormality in hepatitis. It is hoped that they will be found useful by those who have lost faith in the older tests and have not been able to adopt the "battery" method of approach. While no combination of tests will give a definite diagnostic answer in every case of jaundice, the methods described here appear to be reliable in a high proportion of cases with a reasonably small expenditure of labour and materials.

### Material

This consists of 200 consecutive jaundiced patients (serum bilirubin concentration over 2 mg. per 100 ml.) seen per-

sonally during the last four years in whom the cause of the jaundice was satisfactorily established by methods independent of the tests themselves, to the satisfaction of the clinician in charge of the case. Table I gives a detailed

TABLE I.—200 Cases of Jaundice

Diagnosis	Obstructive	Acute Hepatitis	Chronic Hepatitis	Haemolytic
No. of cases .. ..	56	118	15	11
Basis for diagnosis:				
Clinical .. ..	9	108	8	11
Operative .. ..	25	3	3	—
Necropsy .. ..	22	7	4	—
Age in years:				
Average .. ..	56.7	33.2	39.7	45
Range .. ..	24-76	17-71	10-58	22-64
Duration of jaundice (weeks):				
Average .. ..	6.5	1.4	53	29.7
Range .. ..	1-72	0.2-8	5-250	1-100

Average .. ..	9.7	6.8	3.8	2.9
Range .. ..	2-24	2-25	2-8.3	2-8.1

analysis of the cases, on which the following comments may be made. The obstructive cases show, as would be expected, a higher average age and serum bilirubin than the other groups, and their average duration of jaundice (6.5 weeks) was intermediate between acute hepatitis on the one hand (1.4 weeks) and chronic hepatitis on the other (53 weeks). The obstruction was due to neoplasm in 37 cases, to gallstones in 17, and to lymphadenoma in 2. Diagnosis was by operation or necropsy in 47 of these 56 cases. The 118 cases of acute hepatitis were made up as follows: infective hepatitis (95), post-arsphenamine jaundice (13), jaundice with peritonitis (3), homologous serum jaundice (2), trinitrotoluene jaundice (2), glandular fever (1), leptospiral jaundice (1), eclampsia (1). There were six fatal cases of acute hepatic necrosis in the infective hepatitis group, and the patient with eclampsia also died. Chronic hepatitis cases were mainly of multilobular cirrhosis, but included five cases of chronic jaundice following acute hepatitis and one of Banti's syndrome. The haemolytic jaundice was classified as acholuric in four cases, post-transfusion in three, and of unknown aetiology in four.

### Methods

1. *Serum Alkaline Phosphatase* (King and Armstrong, 1934).—Normal limits, 3-13 units. This method was latterly modified to use 0.2 ml. portions of serum, and the results were read on the King-Gallenkamp photo-electric colorimeter, but the original barbitone buffer was retained throughout.

2. *Serum Colloidal Gold Reaction*.—The buffer methods of MacLagan (1944a; 1946b). These two methods have been

shown to give the same results, but the later one employs an easier method of preparing the gold sol.

3. *Thymol Turbidity Test*.—The original method (MacLagan, 1944b) was used throughout except for a slight change in the turbidity standards noted below. This technique has now been used satisfactorily by a number of workers (Watson *et al.*, 1945; Cohn and Lidman, 1946; Havens and Marck, 1946; Maizels, 1946; Klatskin and Rappaport, 1947; Mawson, 1947), but as others have reported certain difficulties or modifications the following additional technical notes may be of interest.

(a) The pH of the thymol buffer was originally given as 7.8, but Volwiler (1946) found it to be 7.67 and adjusted it to 7.8 by the addition of more sodium barbitone, which would also have the undesirable effect of raising the ionic strength. Mateer *et al.* (1947), on the other hand, agreed with pH 7.8, but found their reagent too insensitive and adjusted the pH to 7.55. Some of these differences may well be due to difficulties inherent in the standardization of pH measurements, such as temperature effects and choice of check solutions. The value of pH 7.8 was obtained with the glass electrode (Marconi) at 20° C. using M/20 potassium hydrogen phthalate as a standard of reference with a value of 4.0, and is in fair agreement with the pK value of diethyl barbituric acid, given by Britton (1942) as 7.92. It should, however, be emphasized that the buffer was designed to have a salt-acid ratio of 2:3 rather than a pH of exactly 7.8. It is of course quite possible to increase the sensitivity of the reagent by lowering the pH, but data previously presented (MacLagan, 1944b) indicate that this would probably have the effect of diminishing the specificity of the reaction. In any case it would seem to be inadvisable to make any alterations in the buffer purely on the basis of the pH measurements, which are in general hardly accurate enough for this purpose unless very special precautions are taken. It is probably more important to check the purity of the reagents, as the possibility exists that certain brands of sodium barbitone may contain an excess of alkali and therefore yield an incorrect buffer. Thus 0.416 g. of the sodium barbitone should require exactly 20 ml. of 0.1 N hydrochloric acid for titration to methyl orange, and the barbitone should melt at  $190 \pm 1^\circ \text{C}$ . (uncorrected). A rough check on the final pH with phenol red is a useful safeguard. Finally, an undue proportion of negative results such as those of Mateer *et al.* (1947) would obviously suggest the need for investigation, and as a rough guide the positives in a series of cases of epidemic infective hepatitis should amount to at least 90%. In the present work no readjustment of the buffer has been found necessary.

(b) Various photometric methods of measuring the turbidity have been published (Shank and Hoagland, 1946; Ley, Lewis, and Davidson, 1946), in which the measurements are standardized against barium sulphate suspensions. I have had difficulty in getting reproducible results with methods of this type, and in the present series visual comparison was adhered to throughout. The standards have, however, recently been made up from diluted normal serum of known protein content treated with three volumes of 3% sulphosalicylic acid. These appear to be as stable as the formazine standards and are simpler to renew and control. A similar recommendation to return to the simpler visual comparison was made by several speakers at the Conference on Liver Injury, New York, 1946.

(c) The normal limits, originally given as 0 to 4 units, have been criticized, and Neeffe (1946) and Mateer *et al.* (1947) both consider values above 2 units as abnormal. This question seems to depend upon the choice of normal controls, and there is no doubt that completely healthy persons do give lower figures than those I obtained on "non-hepatic" hospital patients. Values between 2 and 4 units are relatively frequent in disease apparently unconnected with the liver, and it was in an effort to avoid these "false positive" results that the limits of 0 to 4 were suggested. However, if the test is being used for screening purposes on apparently healthy persons, the limits of 0 to 2 would no doubt be more appropriate. These considerations would not affect the arguments used in the present paper, in which an identical diagnostic significance has been accorded to negative and weakly positive flocculation tests.

4. *Thymol Flocculation Test*.—This is performed as an adjunct to the thymol turbidity test by allowing the tube to stand overnight and recording flocculation, as recommended by Neeffe (1946) and MacLagan (1947). Some difficulty was experienced in grading the amount of flocculation consistently, and eventually the following procedure was adopted. If flocculation was complete the amount was related to the turbidity reading with the following convention:

Turbidity units	0-4	5-7	8-10	Over 10
Flocculation (if complete)	1+	2+	3+	4+

Any case showing incomplete flocculation was recorded as 1+, and absence of flocculation as 0 or negative.

## Results

The results are shown in Figs. 1, 2, and 3. It will be seen that there is a clear general tendency for the obstruction cases to have high phosphatase values and negative flocculation reactions (top left-hand corner), while cases

FIG. 1.—Thymol turbidity test.

of hepatitis usually have positive flocculation reactions and normal or moderately raised phosphatase figures (bottom right-hand corner). The cases of haemolytic jaundice tend towards the bottom left-hand corners—that is, they have low phosphatase values with normal or weakly positive flocculation reactions. An intermediate zone contains cases of all types.

In interpreting the results it is of the greatest importance to distinguish between those of diagnostic value (unshaded in charts) and those which are equivocal and not of diagnostic value (shaded in charts). In this respect the following conclusions apply to all the 200 cases without exception:

1. All cases with phosphatase levels above 42 units were obstructive (26 cases). All with phosphatase levels below 15 units were non-obstructive (67 cases); it should be noted that all the 11 cases of haemolytic jaundice are included in this group.
2. All cases with strongly positive flocculation reactions were non-obstructive. These include: 92 cases with 2+, 3, or 4+ thymol flocculation; 60 cases with 4 or 5+ gold reactions; and 55 cases with thymol turbidity over 8 units.

FIG. 2.—Thymol flocculation test.

3. All cases with negative or weakly positive flocculation reactions and, in addition, phosphatase levels above about 35 units were obstructive. These include: 38 cases with thymol flocculation 0 or 1+ and phosphatase above 35 units; 37 cases with thymol turbidity below 9 units and phosphatase above 35 units; and 34 cases with gold less than 4+ and phosphatase over 37 units.

4. All other combinations of results (shaded in charts) can occur in both types of jaundice and should therefore be regarded as equivocal except in so far as a raised phosphatase value is against a purely haemolytic type of jaundice. Nevertheless in cases where they approach the limits of these areas they can obviously be allowed a relative importance in diagnosis. For example, a jaundiced patient with negative flocculation reactions and a phosphatase of 33 units *might* have

FIG. 3.—Serum colloidal gold reaction.

hepatitis, but is much more likely to have biliary obstruction. Similarly, one with weakly positive flocculation reactions and a phosphatase of 18 units *might* have obstruction but is much more likely to have hepatitis.

The alkaline phosphatase results are in close agreement with those of Sherlock (1946), although expressed in a different form. Sherlock gives 30 units as a rough dividing-line between obstructive and non-obstructive cases, and this would also apply to the present series; such a statement, however, fails to express the equivocal nature of results in the region of 15–35 units, which may occur either in hepatitis or in biliary obstruction, and cannot therefore have decisive diagnostic value. The greater frequency of high phosphatase values in chronic as opposed to acute hepatitis is a finding which is well shown in the charts, and has been referred to elsewhere (MacLagan, 1944c).

The relative merits of the various tests are further illustrated in Table II, which shows the proportions of cases falling in the shaded and unshaded areas in Figs. 1, 2, and 3. It will be seen from this table that a combination of the

TABLE II.—Analysis of Results in 200 Cases of Jaundice

Test	No. Diagnosed	No. Equivocal
Phosphatase	93 (46.5%)	107
Thymol flocculation (T.F.)	92 (46%)	108
Colloidal gold (C.G.)	60 (30%)	140
Thymol turbidity (T.T.)	55 (27.5%)	145
Phosphatase and T.F.	158 (79%)	42
Phosphatase and T.T.	136 (68%)	64
Phosphatase and C.G.	131 (65.5%)	69

All cases in shaded area of Figs. 1, 2 and 3 have been counted as equivocal in this table.

thymol flocculation and phosphatase tests gives the best results, with definite diagnostic information in 79% of cases. The other two flocculation tests in conjunction with phosphatase give a somewhat lower proportion of successful results (68% for thymol turbidity and 65.5% for gold). As opposed to this the best results with any *one* test are 46.5% for the phosphatase and 46% for the thymol flocculation test, so that the advantage of combining the two types of test is evident.

The clinical application of the tests is further illustrated by the following two case reports.

### Case Reports

**Case 1: Hepatitis Simulating Biliary Obstruction.**—A man aged 66 had been jaundiced for two weeks. This had been preceded by anorexia for some weeks following an attack of abdominal pain and vomiting ascribed to food-poisoning, and there had also been a patch of bronchopneumonia during this period with pyrexia to 103° F. (39.4° C.), which had been successfully treated with sulphamezathine. Abdominal pain had then reappeared followed by jaundice with dark urine and pale stools. There had been considerable loss of weight. On examination the liver was enlarged and tender. Cholecystography showed poor concentration of dye. The general picture was thought to be suggestive of malignant disease. The chemical findings were as follows: serum bilirubin, 8.7 mg. per 100 ml.; serum alkaline phosphatase, 17 units; thymol turbidity, 12 units; thymol flocculation, 4+; colloidal gold, 3+. These were strongly in favour of hepatitis, and the patient made a good recovery with medical treatment and has had no recurrence of symptoms.

**Case 2: Biliary Obstruction Simulating Cirrhosis.**—A woman of 43 had been jaundiced almost continuously, with some waxing and waning, for the past 18 months. The illness started with pyrexia and pain in the right shoulder-blade; the urine had been dark and the stools pale throughout. One year previously laparotomy had been performed at another hospital, but no obstruction to the biliary tract had been found. Cholecystectomy had been done and the common bile duct dilated. No improvement in symptoms had followed this operation, and

a diagnosis of hepatic cirrhosis had been made at that time. Clinical examination showed fairly deep jaundice in a well-preserved woman. The liver was enlarged and hard, and there was also clubbing of the fingers and toes. There was no x-ray evidence of calculi. The chemical findings were as follows: serum bilirubin, 10.8 mg. per 100 ml.; serum alkaline phosphatase, 36 units; thymol turbidity, 7 units; thymol flocculation, 1+; serum colloidal gold, 1+; galactose index, 135 (normal, 0-160). These results were strongly suggestive of obstructive jaundice, and a second operation disclosed the presence of a gallstone firmly imbedded in the bile ducts in the region of the head of the pancreas.

### Discussion

In a recent article Ivy and Roth (1943) pose the question "Why do a liver function test?" and discuss the value of a variety of tests, not however including the thymol and gold tests. One reason for doing liver function tests is to distinguish obstructive from non-obstructive jaundice. While admitting the limitations stressed by these writers, it would appear from the results given above that for this special purpose the combination of the serum alkaline phosphatase estimation with the thymol or the colloidal gold test may be expected to provide a reliable answer in a high proportion of cases, the actual percentage varying from 65.5 to 79 according to the particular flocculation test used. The actual diagnostic value of these procedures is in practice rather greater than these figures would suggest, for two reasons. First, there is the inclusion of 13 cases of post-arsphenamine jaundice in the acute hepatitis group. These cases have a particular tendency to exhibit negative flocculation reactions (Maclagan, 1944a, 1944b, 1944c), and are in general easily eliminated on clinical grounds; if they are removed from the series the results, particularly with the thymol flocculation test, would be appreciably better. Secondly, although the cases in the shaded areas of Figs. 1, 2, and 3 have been recorded as failures in Table II, in many cases where the results approach the limits of these areas they were of some diagnostic help, as explained above. Nevertheless, it is true that certain combinations of results can occur in any type of jaundice, and there is probably no test or combination of tests which will give a diagnostic answer in every case.

As regards choice of test, thymol flocculation seems to be the best of the three flocculation tests tried. It is, however, known to be rather often negative in post-arsphenamine and homologous serum jaundice (Maclagan, 1947), and it is therefore desirable to retain the thymol turbidity test. The amount of flocculation can then be recorded more accurately as indicated above. The colloidal gold test has no advantage over the other two in the diagnosis of jaundice, but I retained it because of its greater sensitivity in conditions such as rheumatoid arthritis, malaria, and infective endocarditis (Carter and Maclagan, 1946). It is technically convenient to perform these tests together as they require the same small volume of serum (0.05 ml.).

Although all these tests are still partly empirical in character, it has recently been shown that the underlying chemical change in the case of the flocculation tests is probably a relative excess of gamma globulin in the serum (Gray and Barron, 1943; Kabat *et al.*, 1943; Maclagan and Bunn, 1947a, 1947b). Thus electrophoretically separated serum gamma globulin acts as a precipitating agent, and an absolute increase in this fraction has been demonstrated in hepatitis. Similarly normal serum albumin acts as an inhibitor, and this fraction is often reduced in hepatitis; moreover, hepatitis albumin is less effective as an inhibitor than normal albumin. The rise of the serum alkaline phosphatase in liver disease is, however, incompletely understood, having been ascribed to the phosphatase

content of the bile (Armstrong *et al.*, 1934) and to secondary interference with bone metabolism (Roberts, 1933). It seems more likely to me that this rise represents a positive secretory response of the liver cell to a variety of chemical or bacterial insults, of which biliary obstruction is the most powerful. It is somewhat remarkable that the liver cell damaged by biliary obstruction should fail so uniformly to produce those protein changes associated with positive flocculation tests, but such appears to be the case.

It is not of course suggested that the diagnostic criteria given above will hold generally without any exceptions and in interpreting the results the possible presence of complicating diseases such as heart failure and rheumatoid arthritis should be borne in mind, as these conditions may produce positive flocculation reactions even in the absence of jaundice. However, the fact that no exception has occurred in these 200 cases is an encouraging feature. It is also obvious that the tests described will not elucidate every problem in hepatic pathology, and for special purposes other tests will also be required—for example, the serum protein estimation for prognosis (Higgins *et al.*, 1944) and recent modifications of the pigmentary tests for the diagnosis of non-icteric and pre-icteric hepatitis and haemolytic jaundice (Watson *et al.*, 1944; Pollock, 1945; Watson, 1946; Maclagan, 1946a; Neefe and Reinhold, 1946; Gray, 1947). Such tests are, however, of very limited value for distinguishing obstructive from non-obstructive jaundice which is the special problem considered here, and for which the suggested combination of phosphatase and flocculation tests appears to represent an advance on previous chemical methods of approach.

### Summary

The results obtained in 200 cases of jaundice with the serum alkaline phosphatase, thymol turbidity, thymol flocculation, and serum colloidal gold tests are analysed in relation to the diagnostic value.

The combination of phosphatase with one flocculation test will distinguish obstructive from non-obstructive jaundice in from 65 to 79% of cases. The thymol flocculation test, slightly the best of the three flocculation tests tried.

Diagnostic criteria are given for the various tests. Strongly positive flocculation reactions or phosphatase levels below 15 King-Armstrong units suggest non-obstructive jaundice; negative or weakly positive flocculation reactions with phosphatase levels above 35 units suggest biliary obstruction, and phosphatase levels above 42 units are also in favour of obstruction.

I am much indebted to the medical staffs of Westminster Hospital, Ashford County Hospital, Middlesex, and of E.M.S. Sector 7 for access to their patients and records; to Prof. R. J. V. Pulvertaft, Dr. Alan Morgan, and Dr. A. G. Signy for necropsy reports; and to Drs. J. Amor and J. Marshall for certain sera. Part of the expenses of the work was defrayed by a grant from Westminster Hospital.

## RELATIVE ORAL TOXICITY OF SOME THERAPEUTIC IRON PREPARATIONS

BY

G. F. SOMERS, B.Sc., Ph.C.

Research Division, Glaxo Laboratories Ltd.,  
Greenford, Middlesex

Forbes (1947) and Thomson (1947) have recently described serious consequences in young children, including three deaths, following the unauthorized taking of ferrous sulphate tablets in excessive numbers. These and certain cases previously reported to us raised the general question of the toxicity of iron compounds when large doses were consumed orally, and also of the additional effect, if any, of the small amount of copper and manganese sulphates which were present in the tablets.

Examination of the literature failed to reveal earlier reports of ill effects from orally administered iron compounds, except for occasional references to slight alimentary disturbances. Further, and more surprisingly in view of the widespread use of iron compounds for the treatment of iron deficiency or "nutritional" anaemia, we have been unable to find any account of pharmacological investigations into the action of iron given by mouth, although its effects by injection have received some attention and it is accepted that serious ill effects may follow its absorption into the blood stream.

It therefore seemed desirable to test experimentally on several species of laboratory animal the effects of orally administering very large doses of some of the more commonly used iron preparations. For this purpose we chose ferrous sulphate, with and without the presence of the "trace" metals copper and manganese; ferrous carbonate in the form of Blaud's pills; ferrous gluconate, because of the claims made for it by Reznikoff and Goebel (1937); ferric chloride, so as to include at least one preparation of ionizable ferric iron; and iron and ammonium citrate, widely used in compounded medicines, though nowadays largely replaced by ferrous sulphate for simple oral iron therapy—shown by many workers from Davidson (1933) onwards to be much more effective in haemopoiesis than the non-ionized "scale salts," when compared on an equivalent iron basis. Rabbits and guinea-pigs were used for studying the pathology and histology of any disturbances observed, and mice for the estimation of median lethal doses (LD50) with reasonable accuracy.

As a practical problem in human therapeutics we were really concerned with establishing the "therapeutic index" of ionizable iron—that is, the ratio of its median toxic dose to its median therapeutic dose. Here we encountered two difficulties, the one general and the other particular. First, it is ordinarily impossible to establish such an index for the action of a drug on the human organism, simply because data, unfortunately, are not as a rule available for the median toxic human dose. The pharmacologist therefore normally has recourse to establishing the therapeutic index of a drug on at least one species of laboratory animal, and preferably on more than one. If the value of this index is of roughly the same order for two or more species of laboratory animals it is reasonable to assume that the same value will apply to man; in general, experience bears out this assumption. However, even this line of approach was not available to us, for there is no species of animal—with the possible exception of the rat made anaemic on a milk diet—for which we have information about the median therapeutic dose of iron compounds.

We were consequently forced back on to the unsatisfactory step of relating toxic doses to the body weight of the animal used and arguing on the same basis for man. The objections to this line of reasoning, however, appear much less strong for iron compounds than they might for other drugs, for it will be seen that toxic effects—and, in particular, fatal results—were produced only by doses so immensely out of proportion to the animal's normal intake of iron as to make highly unlikely the ingestion of dangerous amounts by human subjects. The facts established by our experiments nevertheless make it clearly desirable to render access of infants and small children to iron preparations as difficult as possible. Such precautions would normally be taken with many of the common drugs to be found in the ordinary household—for example, quinine salts and acetylsalicylic acid—without in any way detracting from their value and importance in therapeutics.

### Toxicity

The results obtained with the three species of animals used are summarized in the accompanying table. The

Table showing the Median Lethal Toxic Doses of Iron Compounds by the Oral Route

Compound	Iron in Preparation, Calculated as Fe	Dose per kg. of Body Weight					
		Rabbits		Guinea-pigs		Mice	
		Actual	Cal. as Fe	Actual	Cal. as Fe	Actual	Cal. as Fe
Ferrous sulphate crystals	20	3.0	0.6	1.5	0.3	2.5	0.9
Ferrous sulphate prep. with copper and manganese	24	3.0	0.72	1.25	0.3	4.1	1.0
Ferrous gluconate	16.6	3.5	0.58	2.1	0.35	6.6	1.1
Ferrous carbonate pills	12.5	17.8	2.22	16.0	2.0	31.0	3.8
Ferric chloride	32.5	1.2	0.4	0.6	0.2	1.5	0.5
Ferric and ammonium citrate	20	2.8	0.56	1.75	0.35	5.0	1.0

figures from tests on rabbits and guinea-pigs, owing to the relatively small numbers of such animals that can be used in toxicity tests, must be regarded as first approximations: the figures from the tests on mice have a greater accuracy, except those for iron and ammonium citrate, because with this product a great individual variation was found among the animals. Slopes of the regression curves, and the errors of estimating the LD50, which were of the order usually found in tests of this kind, were obtained by the graphical method of de Beer (1945).

It will be seen: (1) That the presence of small amounts of copper and manganese sulphates made no difference to

the toxicity of the iron or ferrous sulphate. (2) That the iron in ferrous sulphate, ferrous gluconate, and—curiously enough—iron and ammonium citrate had the same toxicity, though it must be repeated that the figure for the last compound is subject to a very large error. (3) That the iron in Blaud's pills has apparently only about one-quarter the toxicity of the other forms. It is, of course, well known that the iron in Blaud's pills has also much less therapeutic effect, and these two facts are undoubtedly due, at least in part, to the same basic phenomenon—the relative insolubility of their ferrous carbonate in gastric and intestinal contents. (4) That ferric iron appears to be up to twice as toxic as ferrous iron. We have no explanation for this finding, especially if, as is generally held, ferric iron is reduced in the stomach to the ferrous state. It must, however, be remembered that ferric chloride is a much more acidic substance than ferrous sulphate (or gluconate). The introduction of large quantities into the stomach must involve a considerable increase in gastric acidity, which in turn may hasten alimentary absorption of the iron—possibly an advantage with therapeutic doses but certainly not with toxic ones.

The observation with Blaud's pills suggested that sodium carbonate or bicarbonate might be useful as an antidote to toxic oral doses of iron compounds. Four rabbits were therefore given known toxic doses of ferrous sulphate (3 g. per kg. of body weight) and two of them then received the same amount of sodium carbonate. One of these two lived for two days, while the other survived completely; the two that did not receive sodium carbonate died overnight. This experiment was repeated twice, with similar results—a fact which points to the conclusion that sodium carbonate treatment might, if given soon enough, help to reduce the toxic effects of excessive iron doses by mouth.

### Pathology and Histology

#### Rabbits

The rabbits used were of both sexes and weighed between 2 and 3 kg. They were fasted overnight and were then given by stomach tube doses of the iron compounds, graded and proportionate to their body weights. Two animals were used for each dose and at least ten animals for each substance. If the rabbits survived, daily samples of urine were collected for three days. Haematological examinations included differential and total counts of red and white cells and estimates of haemoglobin levels. Necropsies with examination of all major organs followed as quickly as possible after death. Sections were cut of parts of the stomach, intestine, liver, and kidneys, and were stained for iron as well as with haematoxylin and eosin.

Within a few minutes of receiving a toxic dose of iron the rabbits became prostrated. They lay on their stomachs with limbs extended, their respiratory rate increased, micturition often occurred, and reflex movement of the hind legs was considerably retarded. Coma followed, with shallow breathing and gradual disappearance of reflex movements. The animal either died two to six hours after receiving the dose (according to its size), sometimes following convulsions, or recovered.

The rabbits receiving Blaud's pills had a profuse diarrhoea. This fact, with the freedom of all other animals from this symptom, has, we believe, a very simple explanation. The pills are made by reacting ferrous sulphate with sodium carbonate, so that the ferrous carbonate formed must be accompanied by an equivalent amount of sodium sulphate. There seems no reason why a large dose of Glauber's salts should have an effect on rabbits differing from that on man. Moreover, the laxative effect of the associated sodium sulphate must have hastened the alimen-

tary passage of these large doses of ferrous carbonate: this would tend further to reduce its toxic effects.

At necropsy the stomachs usually showed congested areas with shedding of mucosa, especially at the greater curvature. The amount of damage was to a large extent determined by the size of dose: the smaller toxic doses caused only very slight damage to the stomach wall. Bleeding into the stomach was the exception rather than the rule, but it was seen after the larger doses of both ferrous sulphate and ferric chloride and in one animal that had received ferrous gluconate. The small intestines generally showed much hyperaemia in their upper regions, but here also haemorrhages were seen only after very large doses. Surviving animals showed no evidence of kidney damage, the urine being invariably devoid of abnormal constituents. There were no departures from normal blood counts. Recovery of surviving animals was usually rapid.

Changes in the histology of stomach, liver, and kidney in rabbits killed by the iron compounds were very small, and appeared insufficient to account for the death of the animals. In the stomach there was only slight necrosis of the superficial layer of the villi and deposits of iron on the mucous membrane (occasionally also in the endothelium of the smaller blood vessels). There were deposits of iron in the bile ducts, but only slight hydropic changes in the liver. In rabbits surviving and killed three days after dosing we observed small foci of fatty degeneration, and necrosis was present in the peripheral parts of the lobuli, with deposits of iron, mainly in the Küpffer cells. The other surviving animals appeared to be completely restored to normal health and activity after a few days.

#### Guinea-pigs

The animals used, of either sex, weighed between 200 and 300 g. Their distribution over the different dosage groups was made so far as possible to equalize the average weights of the groups. Each dose was given to at least three animals, and at least ten guinea-pigs were used for each substance tested. The animals were fasted overnight and given the appropriate dose of iron compound by dropping it into the mouth and then tickling the fauces. Necropsies, dissections, and histological work were carried out as on the rabbits.

In general the immediate consequences of excessive iron administration by mouth were the same in guinea-pigs as in rabbits. At necropsy, however, there was evidence of severer damage to the stomach; macroscopically the findings with the larger doses resembled those described by Forbes. After doses of 1.5 g. per kg. of body weight of ferrous sulphate or ferric chloride the stomach contained both fresh and changed blood; necrosis, shedding of mucosa, and areas of haemorrhage were obvious to the naked eye. Severe irritation of the stomach wall followed the ingestion of 3 g. of ferrous gluconate per kg. of body weight: in one animal the stomach was full of blood-stained material. Changes were less severe after dosing with iron and ammonium citrate or Blaud's pills, but at the larger dose levels either preparation caused well-marked irritation of gastric mucosa with occasional petechial haemorrhages.

Histological changes, as in rabbits, were slight and insufficient in themselves to account for the deaths. There was but superficial damage to the gastric villi, with deposit of iron on the mucous membrane, which also showed some areas of capillary bleeding. In a very few instances there were some fatty changes in the liver.

Necropsies were not made on mice, which were used solely to obtain a reasonably accurate estimate of the median lethal doses.

### Discussion

From the experiments described there can be no doubt that in very large doses certain soluble iron salts, whether ferrous or ferric, whether of organic or inorganic acids, and whether normally ionizable or complexes of the "scale salt" type, are toxic to at least three species of laboratory animals. It is reasonable, and probably a wise precaution, by extrapolation to accept as proved that all similar iron compounds can, in excessively large doses, kill mammals of any species, including man. It must, however, be emphasized that toxic doses really are excessive. The amount of ferrous sulphate necessary to kill on the average one out of two 10-stone (63.5-kg.) men, if man's susceptibility on a body-weight basis is assumed to be the same as that of the rabbit, would represent at least several hundred tablets of 3 gr. (0.2 g.) of exsiccated ferrous sulphate, each containing 1 gr. (65 mg.) of iron. Obviously the number may be considerably smaller for infants and young children, being reckoned in tens rather than hundreds.

The similarity in behaviour of various iron preparations suggests that after solution in the stomach they are all reduced to the ferrous state and that ferrous iron when present in very large amounts, whether wholly ionized or not, is alone responsible for the damage. Ferrous sulphate should be completely ionized at high concentrations, and ferrous gluconate probably hardly ionized at all even at low concentrations, yet they show indistinguishable toxicities in very high doses. It may be remarked, in passing, that none of the ionizable iron compounds exists as such in the stomach after therapeutic doses: apart from un-ionized hydrochloric acid in the gastric contents, there will then be present in solution the chloride, sulphate, and other anions, the hydrogen, iron, and other cations, and the various un-ionized soluble constituents. Forbes's contrasting of ferrous sulphate with ferrous chloride in solution therefore seems to be misleading even when the sulphate has been ingested at much above the therapeutic level.

The post-mortem and histological examinations have furnished no positive information about the *modus operandi* of iron at orally toxic levels. A decision between shock due to tissue damage—which at worst was not very great and appeared rapidly reversible in the milder cases—and systemic effects following passage of excess iron into the blood stream cannot be made on the basis of our experiments. They were, in any event, carried out with an immediately practical object—to find and record at what doses therapeutic iron preparations could exert toxic effects on experimental animals. The results of these experiments are reassuring. They show, at any rate in so far as the experimental animals react similarly to man, that the gap between curative and harmful doses of iron compounds is very large—and obviously still larger between preventive and fatal doses. Indeed, I doubt if there are many medicinal substances with so large a "therapeutic index." The upper dose of ferrous sulphate, according to the *British Pharmacopoeia*, is 0.3 g., which would be contained in five tablets of the product causing fatalities that led to this investigation. In few circumstances is it likely that an adult would be recommended to take more than 12 such tablets a day, and the results suggest the harmlessness of anything less than several hundred tablets taken all at one time and on an empty stomach. It is, however, desirable that physicians and pharmacists should warn parents and adults generally that iron preparations should be kept out of reach of the very young.

In the experiments described above I have received the technical assistance of Mr. G. A. Romer in the preparation of sections and slides, and much useful advice from Dr. J. Ungar, to both of whom I wish to extend my thanks.

AND

D. R. THOMPSON, M.R.C.S., L.R.C.P.

Medical Officer, De Havilland Aircraft Co., Ltd., Hatfield

During the recent war, with its urgent demands for manpower, the attention of the medical services was sharply focused on to an aspect of clinical treatment that had under less pressing conditions been of relatively secondary importance. The economic aspect of medical or surgical treatment assumed an importance equal to that previously held by the somewhat ambiguous criterion of a "good clinical result." This is none the less true of to-day. The essence of the problem facing the clinician from the first day of treatment onward can best be expressed in the form of the question: How may this man be returned to his accustomed way of life and employment with a minimum loss of time and skill? The answer to that question embodies the full significance of the term "Rehabilitation," which must include the repair of the injury as well as the restoration of functional efficiency.

In industry to-day there are several examples of the successful handling of the problem of rehabilitation of the injured workman by a close liaison between medical and industrial authorities, the responsibility of treatment being shared equally between the two. Such schemes are at the present time too elaborate and costly to be undertaken by the smaller concerns. In this paper we have briefly described an experimental rehabilitation scheme carried out during wartime. We have attempted to underline the principles of treatment and to show how such a scheme may be applied to the industrial injuries of peacetime, with the minimum of special equipment, under existing factory conditions.

### The Scheme

During 1945 and 1946, thanks to the co-operation of a near-by aircraft factory, a number of long-term Service and ex-Service cases drawn from the orthopaedic, plastic, and peripheral nerve injury units of Hill End Hospital were sent to work in the factory in chosen occupations. The choice of Service men, the majority complete strangers to factory life, was governed partly by the preponderance of Service casualties and partly by the special problem that they offered. As already stated, they were mainly "long-term" cases requiring a series of reconstructive operations or a long course of physiotherapy. It was thought that this experiment might have the double advantage of providing selected remedial exercises and, at the same time, a much-needed change of surroundings.

Sixty-nine patients took part in the scheme, spending an average of 63.9 hours at work over a period of seven weeks. Attendance at the factory was on four afternoons a week from 1.30 to 4.30; the mornings being left free for attention in the physiotherapy department. It was considered of the utmost importance that the scheme should be an adjunct to regular physiotherapy rather than, in any way, a substitute for it (see below).

Clinical control of the scheme lay in weekly factory "rounds" by the surgeon in charge of the case, the works medical officer, and the hospital rehabilitation officer, when the methods employed were discussed and criticized. The jobs, all of which came under the heading of unskilled work, were chosen from a large variety of industrial operations in accordance with the requirements of the disability. Some examples of these jobs are: bench assembly work, light assembly work in a warm electroplating "shop," drilling (using bench drill and single-spindle drill), hacksawing, Lister truck driving, preparation of fuselages, press operating, spray painting, and dismantling wrecked aircraft.

Many production operations, including those mentioned, demand movements which in certain conditions are of remedial value: the movements are for the most part both *repetitive* and *controlled*—two factors which count for a great deal in this connexion. Furthermore, by *simple* adaptation many of the jobs can be altered to suit the strength or range of the operator. Thus by varying the effective length of the operating lever the power required to work a drill may be stepped up or down. Again, by simple alteration of the *height* of the operating handle of a machine a gradual increase in range of, for example, the shoulder-joint can be encouraged.

This series of 69 cases included 53 of upper-limb injury, 46 (87%) of these resulting from gunshot wounds. The upper-limb injuries were various, and included a large number of disabilities which, from the point of view of rehabilitation, offered three main problems that could be summarized broadly under the clinical headings of joint stiffness, loss of muscle power, and muscle contractures. There were in this series no cases in which joint stiffness was present alone. In 26 cases (49.1%) it occurred in association with loss of muscle power, and in 10 (18.9%) it was present in association with both muscle contractures and loss of muscle power. Loss of muscle power was present alone in 11 cases (20.7%), was associated with muscle contractures in 6 (11.3%), and was associated with both joint stiffness and muscle contractures in 10 (18.9%). In no case was muscle contracture the only pathology.

#### (1) Joint Stiffness

Functional inactivity with resulting venous and lymphatic stasis is the most frequent factor in the production of post-traumatic joint stiffness (Watson-Jones, 1943). Prolonged inactivity results in irreversible changes occurring in capsular and ligamentous tissues, with the formation of intracapsular adhesions. Attempts to increase the range of movement by *passive forcing* of such joints often result in further damage to the soft tissues, with further limitation of movement. Bearing these precepts in mind, the problem of overcoming joint stiffness was approached mainly from the point of view of *active mobilization*.

One man had severe limitation of the elbow-, wrist-, and finger-joints as a result of seven months' immobilization and disuse of the right upper limb on an abduction frame for the treatment of a gunshot wound of the shoulder region which involved the brachial plexus. The patient was first put to work on light assembly in the electroplating shop, where the temperature is maintained at between 80° and 90° F. (26.6° and 32.2° C.). He was later transferred to hacksawing, an occupation requiring great muscular effort and involving all the joints of the

upper limb, including the shoulder-joint. The hacksaw was modified by padding the handle to allow him to grip it firm within the range of his metacarpo-phalangeal joint movement (Fig. 1). This produced a pronounced improvement of mus-

FIG. 1.—Patient using hacksaw with padded grip.

power associated with a greatly increased range of joint movement throughout the limb. As the metacarpo-phalangeal joint flexion improved, the padding of the handle was reduced.

The beneficial effect of prolonged active and resistive movements in a warm atmosphere was most marked.

A man whose fingers were almost immobile as a result of a gunshot wound of the hand responded notably to an occupation designed to give him active movements in a warm atmosphere. He drove a Lister truck on light haulage jobs within the factory precincts; the frequent stops and starts necessitated almost continual use of the clutch handle, which he operated with his injured hand, and which was situated in the stream of hot air from the motor.

Where the joint stiffness was not so severe less specific and controlled operations were applied. Among those which proved valuable was one in the salvage department where a spanner was the main instrument and a high degree of mobility of the hand was necessary.

#### (2) Loss of Muscle Power

Restoration of muscle power in cases uncomplicated by joint stiffness, flexion contractures, or nerve lesions offers few problems in treatment if a graduated scale of exercise was provided. When complicated by stiffness of joints, improvement of muscle power is no less important. "A stiff joint with powerful muscles is less disabling than a mobile joint with powerless muscles" (Watson-Jones, 1944). It was found that industrial operations designed primarily to increase joint movement might fail in this, but, as a result of increased muscle power, improve the efficiency of joint movement within its limited range. Where loss of muscle power resulted from denervation atrophy more carefully graduated control of work done was required. Muscles show a return of voluntary power after recovery from a lower motor neurone lesion very extremely rapidly, and it is advantageous to encourage the use of splints where possible. It must, however, be borne in mind that splinting in peripheral nerve injuries is designed to compensate, far as is possible, for the paralysis and to encourage active

ovement rather than to restrict movement. In a recover-  
g radial or post-interosseous nerve lesion a "cock-up"  
oint not only releases the re-innervated wrist extensors  
om the effect of gravity but puts the antagonists at a  
sadvantage. The active contraction of the extensors of  
wrist is in no way interfered with by his manœuvre.

#### ) Muscle Contractures

A large proportion of patients treated in this scheme were  
ffering from peripheral nerve injuries. The frequent  
currence in median and ulnar nerve lesions of fibrous  
uscle contractures affecting flexor muscles of the fore-  
m presented a special problem. Whether the fibrous  
ntracture resulted from a true ischaemic lesion, a de-  
ervation atrophy, or a simple muscle destruction, the  
inical picture varied only in degree. The principle  
lopted in treatment of these contractures was a gradual  
ssive stretching of the muscle, using the wrist as the  
lcrum, the fingers being maintained in extension  
roughout.

A patient who sustained a gunshot wound of the upper arm  
using an axonotmesis (Seddon, 1942) of the median and  
nar nerves had a severe flexion contracture of the fingers of  
ghteen months' duration. When he started work on sand-  
papering aircraft fuselages his degree of contracture allowed  
m to work only on the upper surface of the fuselage (Fig. 2).  
e was encouraged to work down the curved surface of the  
selage, thus gradually and necessarily extending his wrist

FIG. 2

FIG. 3

FIG. 2.—Patient sandpapering fuselage on its upper aspect. The wrist cannot be extended further without compensatory clawing of fingers. FIG. 3.—Showing wrist extension achieved after three months' treatment.

FIG. 4.—The hand in position on the adapted fly-press.

while maintaining the fingers in extension until, as shown in Fig. 3, the contracture was sufficiently overcome to permit him to sandpaper the side of the fuselage with his wrist in dorsiflexion. The result was achieved in 131 hours, covering a period of three months.

Another method employed to give a similar effect is shown in Fig. 4, which illustrates a fly-press with a modification plate attached to the handle. Forward pressure with the flat of the hand is required to operate the press, thus forcibly extending the wrist, the fingers being maintained in extension against the plate by a leather cuff. Over-extension at the metacarpo-phalangeal joints is prevented by means of a padded fulcrum placed behind the metacarpal heads.

Another patient gained 45 degrees of wrist extension with no further compensatory clawing in 117 hours during a period of three and a half months. In both cases corrective splinting was used, and daily physiotherapy was given over the whole period. When seen one year later neither case showed a recurrence of the contracture.

#### Comment

At first sight it would seem that the experiment described above can have little application to an industrial rehabilitation scheme. The patients were not factory workers and the injuries were in the main not those usually associated with industrial accidents. However, as we have already stated, most upper-limb injuries, whatever their origin, may ultimately present one or more of the triad of joint stiffness, loss of muscle power, and muscle contracture. Such differences that occur are mainly in degree. It is certainly true to say that the injuries dealt with in this experiment were more extensive and of longer standing than those commonly met with in industry. In the acute injuries of industry the problem confronting the surgeon is more likely to be prophylactic than remedial. That is to say, he will more often be concerned with the prevention of onset than with the treatment of the established triad.

We have already laid stress on the importance of the continuation of physiotherapy throughout the period of industrial rehabilitation, and provision was made that this side of clinical treatment was not interfered with. There are certain aspects of remedial treatment that can be carried out only in a properly equipped physiotherapy department and for which industrial rehabilitation can offer no substitute. For example, no amount of active movement of a limb will prevent ultimate fibrous-tissue replacement occurring in a denervated muscle which requires daily galvanism if rapid progressive atrophy is to be minimized (Bowden, 1945; Jackson and Seddon, 1945). There is evidence, however, that passive movement of the denervated muscle is beneficial in preventing the onset of muscle contractures.

In regard to mobilization of stiff joints, much can be done in the physiotherapy department, where the skilled application of heat in the form of wax baths or ray treatment, combined with careful active and passive movements, is in the early stages of greater value than any of the industrial methods. On the other hand, a variety of industrial operations offer unrivalled opportunities for encouraging active mobilization of stiff joints through the improvement of muscle power transmitted over them.

The modern occupational therapy department offers ample opportunity for improvement of muscle power, but in relation to an industrial accident service it has the obvious disadvantage of keeping the workman away from his work rather than getting him back to it. However, the occupational therapy department, with its varieties of hand looms, bicycle fretsaws, printing presses, etc., need not be very far removed from the concept of a hospital workshop equipped with a variety of simple industrial machines that might well

form as it were the "nursery slopes" from which the injured workman graduates to his own factory.

Although the inferences of this paper have been drawn from experience of "long-term" cases, much has been learnt about the possible application of such results to the treatment of acute injuries. Apart from the prophylactic aspect—the prevention of adhesions and loss of muscle tone—recently injured joints and muscles appear to respond rapidly to the controlled industrial methods of rehabilitation of this type. Furthermore, when the injury is of industrial origin the early return of the absentee to full-time or part-time selected work not only prevents a loss of skill and a lowering of morale that so often follows in the wake of prolonged unemployment but also tends to reduce the exaggerated importance attached by the workman to the accident.

### Summary

This paper presents an experiment in the rehabilitation of injured Service men using existing conditions in industry.

The principles of treatment are discussed and illustrated.

From the inferences made the application of such a scheme to a peacetime industrial accident service is discussed.

We are indebted to Dr. W. J. T. Kimber, medical superintendent, Hill End E.M.S. Hospital, for help and advice on the organization of the scheme; to all sections of the De Havilland Aircraft Co., Ltd., for their willing co-operation; and to Mr. S. L. Higgs and Mr. Rainsford Mowlem for permission to publish the cases.

## ACQUIRED SYPHILIS IN CHILDREN

BY

MARJORIE MURRELL, M.B., D.P.H., F.R.C.S.Ed.  
*Clinical Tutor*

AND

MARY SCOTT GRAY, M.B., Ch.B.  
*Clinical Assistant*

*Venereal Diseases Department, Edinburgh Royal Infirmary*

To the great increase in early syphilis during the war years may be attributed the emergence of cases of acquired syphilis in children. Six cases are here recorded in order to focus attention on the possibility that the disease is transmitted through close contact with actively infectious individuals, either adults or children, and by contact with infected articles, and on the possibility of such transmission occurring even in families where there are no known cases of syphilis. For example, several children have been brought for examination because they had picked up and inflated condoms found in the parks, and one of the cases reported may have been infected in this way. Poor environmental conditions, carelessness, and lack of attention to hygienic precautions are not invariably present as contributory factors, as infections through contacts have occurred in professional homes. The early recognition of these cases is of such vital importance, both to the child and to those in close contact, that acquired syphilis as a possible diagnosis should be considered in any case in which there is a rash accompanied by headache, sore throat, and adenitis, and where the rash does not conform to the commoner skin conditions or to one of the other exanthemata. The frequency of the commoner symptoms and signs of secondary syphilis in this group of cases is shown in Table II.

Unfortunately, in no case so far has syphilis been suspected while still in the primary stage, although a primary sore on the tonsil was detected in two of the secondary cases now reported. If a chancre appears on the lip, characteristically as a solitary indurated erosion with accompanying unilateral indolent rubbery enlargement of the neighbouring lymphatic glands, it should not be missed, and yet experience shows that suspicion is often not aroused until the secondary stage is reached. All the cases in the present series had had symptoms for three or four weeks before arriving at the clinic.

In the past five years six cases have been examined and treated. Tables I and II give the chief points noted. In

TABLE I

Case No.	Date Seen	Age (yrs.)	Sex	<i>T. pallidum</i> Demonstrated	Site*	Source of Infection
1	4/1/45	3½	M.	+	Anus	Mother

6	—	—	+++	—	+	—	—	++	+

each case the Wassermann and Kahn tests of blood taken at the patient's first appearance were strongly positive, and the cerebrospinal fluid, taken in all except one case within the first fortnight, gave entirely negative findings in respect of cell count, globulin estimation, Wassermann reaction, and gold-sol test.

### Diagnosis

A detailed history of the illness should be obtained, noting particularly the time incidence of the various symptoms. As a rule malaise and anorexia are early symptoms, then follows the rash and sore throat with adenitis, the condylomata in the genital or anal regions being late in appearance. Should, however, the primary sore be on the mouth or tonsils, the first symptoms will be referred to this area, and in that case the associated glandular enlargement is very noticeable and is usually commented upon.

The family history should be obtained in full, with particular reference to whether the parents have ever had treatment for syphilis. An inquiry should be made as to who sleeps with the child and looks after him; whether he keeps his own towels and washing things; whether he uses outside lavatories; and whether he has been staying away from home recently. A thorough examination should then be carried out from head to foot, noting especially the condition of the hair and scalp, mouth, skin, glands, and genitals. Serum should be taken from moist lesions, after ascertaining whether antiseptics or ointments have recently been applied, and blood taken for Wassermann and Kahn tests.

**Differential Diagnosis.**—All the other infectious diseases associated with rashes must first be eliminated, particularly rubella, which was diagnosed originally in Case 2. The throat infection may also be suspected—diphtheria, Vincent's angina, and streptococcal tonsillitis with a streptococcal rash all being possibilities. In children the rash of

secondary syphilis may easily be mistaken for scabies with impetigo, pityriasis rosea, or toxic rashes in general. Case 4, with numerous early condylomata lata on the vulva, was at first thought to be a case of herpes genitalis. Glandular fever and subacute rheumatic fever should be taken into account when the particular features of adenitis and muscle and joint pains are prominent. It must be remembered, too, that more than one condition may be present at the same time—for example, scabies and a syphilitic rash. If, however, all the signs and symptoms, together with the family history, are taken into account, it is usually easy to make a probable diagnosis, and this can be confirmed at once if *Treponema pallidum* is demonstrated, or in a few days by means of a blood test. It is essential that the parents and all close contacts be examined and blood-tested immediately, and it is advisable to make monthly tests for three months after the last contact for those who have been caring for or sleeping with the child. This maxim is illustrated by the unusual story of Case 6.

### Case History

A girl aged 16 was referred from the ear, nose, and throat department on July 26, 1946, with the diagnosis of primary sore of the tonsil, already confirmed by a strongly positive Wassermann reaction. She still showed typical ulceration of the right tonsil, with marked localized adenitis, but she also showed a generalized rash and adenitis and condylomata around the anus, in the serum from which *T. pallidum* was easily demonstrated. Her family—father, mother, and a sister aged 30 who slept with her—were all examined and tested and found to be negative, and it was a mystery how she had been infected, as she denied any other contact.

On Sept. 13—that is, seven weeks later—a little boy aged 20 months was brought to the department, again diagnosed before admission, this time at the Royal Hospital for Sick Children. In appearance he presented a large square head with bossing of frontal bones, a poor bridge to his nose, and sores on the tongue and lower lip, noticed since August. *T. pallidum* was demonstrated, and blood tests gave Wassermann +++, Kahn +++. He was a nephew of the above patient, and she often visited his home and was very fond of him. It was revealed that his father had had primary syphilis in 1938 while in India. He had been fully treated, and had been observed for two years, with negative tests. There had, however, been either a recurrence or a second infection following a further exposure in 1941, for his blood tests were found to give Wassermann ++, Kahn +, although he had no signs or symptoms. The mother of the boy—an intelligent, co-operative, and clean-living woman—had been previously married, with four children by the first marriage and two by the second. The youngest child was the patient, the older one was conceived before his father went to India and was healthy. The mother had had no signs or symptoms of syphilis at any time and appeared perfectly healthy on examination, but her blood tests gave Wassermann +, Kahn +, and after a provocative injection of neoarsphenamine, Wassermann +++ and Kahn +++. The last member of this unfortunate family to appear was the 22-year-old stepsister of the boy. She reported on Nov. 9 with a history of having noticed swollen glands on the right side of her neck four weeks before, followed a week later by a sore throat and headache, and a rash six days before reporting. *T. pallidum* was demonstrated in serum taken from sores in the mouth, and from moist papules at the anus, and blood tests gave Wassermann +++, Kahn +++. She also was devoted to her small stepbrother and often kissed him. There had been no other possible contact.

### Comment

This sad story emphasizes the necessity for examination of all close contacts as well as the parents in cases of both acute congenital and acquired syphilis in children.

Mention must be made of the treatment adopted in these cases. Although no routine dosage has yet been decided

upon, every case was given parenteral penicillin in hospital in three-hourly doses, day and night, the total dose varying from 1,600,000 to 5,000,000 units per course. Case 3 received 1,600,000 units alone, and for a whole year has shown monthly negative blood tests, with maintained good health. All the other cases have received, in addition to the penicillin, at least one unit course of intramuscular arsenic and bismuth injections. Observation must be maintained for at least two years, with repetition of the cerebrospinal fluid tests before discharge.

We wish to express our gratitude to Dr. Batchelor for his help and encouragement in the preparation of this paper, and to Dr. Clark, the medical officer of health, for permission to publish the cases.

## FACTORS INFLUENCING THE FUTURE PROVISION OF DAY NURSERIES

### LONG-TERM POLICY

*A statement by the Day Nurseries Committee of the Medical Women's Federation adopted by the Council of the Federation.*

It should be the ultimate aim of a policy directed towards well-being in childhood that every mother should have the knowledge, means, time, and accommodation to bring up her own children in health and happiness within the family circle in their earliest years. It is recognized that after about the age of 3 years children benefit from contacts beyond the family circle, especially if the family is small or widely spaced. The provision of nursery schools (already part of the national policy) will increasingly meet this need where a mother is unable to arrange for it herself.

The full achievement of the aim of healthy happy family life in childhood is at present prevented by certain social disorders and conditions, and is likely to be so prevented for many years, probably even indefinitely. Among these social conditions may be mentioned: (a) inadequate housing and overcrowding; (b) circumstances which force the mother to be the sole or main bread-winner of the family (e.g., unmarried mothers, deserted or separated wives, widows, wives with incapacitated or unemployable husbands, etc.); and (c) difficult or bad home circumstances (e.g., illness or incapacity of the mother, poor parentcraft—from the physical or psychological aspect—poverty, drunkenness, etc.).

Day nurseries do not provide the social remedy for these conditions. They do, however, provide a means of alleviating the effects on young children. Other means are available also—as, for instance, home helps, carefully supervised daily minding, and direct financial assistance. Such methods, by retaining a more natural environment for the child, may well be preferable so far as they can be made available. But so long as these social disorders persist to any considerable extent, day nurseries, along with other methods, will be required on a scale commensurate with the extent and seriousness of these conditions in different localities, bearing in mind that for older children nursery schools will also play a part.

The provision of day nurseries should not be allowed to interfere with the radical measures necessary to abate, and not merely alleviate, these social evils—for example, better housing, adequate allowances, and more widespread teaching of parentcraft. As and when social conditions improve, so should health and happiness within the family circle become attainable for greater numbers of children and the need for day nurseries diminish.

For the social disorder of poor parentcraft day nurseries can provide a limited remedy as well as a means of alleviation. The children's life in a day nursery can be an object

## FUTURE PROVISION OF DAY NURSERIES

lesson in child care, and in addition the nursery students are potential mothers. The number of actual or potential mothers who can be reached is extremely small relative to the total parent population. (Even in wartime less than 2½% of the children under 5 years old were in day nurseries.) The need to teach parentcraft is almost universal, and day nurseries absorb too much of the resources of personnel and money to make it practicable to attempt to use them on a scale sufficient to meet this need. It can be more completely met by other educational methods. Nevertheless, the concurrent effect in the teaching of parentcraft is valuable even though it may not be the primary purpose.

**Short-term Policy**

Two circumstances should be considered in relation to the immediate provision of day nurseries: (1) the present widespread prevalence of inadequate housing and overcrowding, and (2) the continuing demand for women in industry. The first of these, though it will also condition long-term policy, is of such seriousness at the present time as to merit special consideration in the continuance of nurseries on a short-term basis. To alleviate the effects of overcrowded and unhealthy housing day nurseries will be needed for a few years on a wider scale than should be necessary subsequently, when the true remedy of better housing becomes more widely available.

The continuing demand for women in industry during the present period of economic reconstruction and the "export drive" brings in considerations of national welfare only indirectly related to child welfare. At the height of wartime provision of day nurseries about 71,000 women were directly released to industry. Intermittent exclusion of children from the nurseries reduced the effective employment of the mothers by about 25%. A further 25% was offset by direct employment of women in running the nurseries. Thus, without taking into account the very considerable volume of labour indirectly employed in the maintenance of nurseries, the gain to industry cannot have been more than the equivalent of about 35,000 women. It must in fact have been very much less, and there may well have been a deficit. When it is remembered that nearly 4½ million men and women have now been released from the Forces, it will be realized that there can be no case for continuing to encourage the employment of mothers of young children, except possibly in certain industries depending mainly on female labour. Where such localized needs exist and are regarded as of importance in national welfare, they can probably best be met by the provision of nurseries in association with the industry concerned. Legislation should be introduced to bring such nurseries under the statutory supervision of the health authority. At present, nurseries that are privately maintained, whether by individuals or commercial firms, cannot be required to conform to any standards in such matters as staffing, premises, and equipment.

**Further Considerations**

In considering the place of day nurseries in the social services for mothers and children, whether on a long- or a short-term basis, certain further considerations merit attention—namely: (a) the provision of part-time occasional nursery care; (b) the need for mothers to be relieved of some part of the constant pressure of family cares; (c) the demand of some mothers to be enabled to work for their own satisfaction, apart from economic or national needs; and (d) the effect of day-nursery life on the health and well-being of young children.

**(a) The Provision of Part-time Occasional Nursery Care**

In the alleviation of some social disorders obviously only whole-time nurseries can help—for example, where the

mother must be the bread-winner or when she is temporarily incapacitated; probably, also, in the worst instances of housing or home circumstances. The effects of many of the social conditions previously mentioned could, however, be considerably alleviated by arrangements for the part-time care of children, say for a few hours at a time or two or three days a week. Such arrangements can be made in association with an existing organization, an instance, a health or welfare centre or a community centre. The simpler set-up and the use of an existing organization allows of a greater number of children being cared for relative to the resources employed—a point worth consideration when many children are living under crowded factory conditions, and when resources, particularly personnel, are limited.

**(b) The Need to Relieve Pressure on Mothers**

Arrangements for the occasional care of children will particularly meet the well-recognized need of almost all mothers of young children for some relief from the remitting pressure of family and household cares. Occasional relief does not conflict with the ultimate aim that every mother should be enabled to bring up her children within the family circle, but rather would tend towards it. A mother can be at her best if she has the time and opportunity to preserve her personality as an individual citizen, and also time for companionship with her husband. Nursery schools will help, but where there are no nursery part-time nursery care is needed also. Time for companionship between husband and wife strengthens the family circle. Daytime care of children will not meet this need. The encouragement of group arrangements for evening "sitters-in" or "good-neighbour" nurseries would help many mothers who cannot make their own individual arrangements to free themselves for at least occasional companionship with their husbands in the evenings. Mention should be made of the fact that family circumstances often arise when even whole-time day-nursery care cannot solve the difficulties—and still less, of course, part-time care. There is a most urgent need for provision of short-term residential nurseries to meet domestic crises in families where there are babies and young children, particularly when adequate care cannot be given in the evening and at night. Although residential nurseries are outside the scope of this memorandum, the question is related to the family care of children, and attention is drawn to the acute need for more adequate means of meeting difficulties of sudden domestic crises.

**(c) The Right of Mothers to Work**

A number of mothers who have no pressing need to undertake work outside the home nevertheless wish to do so for the sake of interest, companionship, or income, if they can make arrangements for the care of their children. The relatively well-to-do mother has been able to satisfy this wish at her own cost by employing a children nurse or governess. The cost and the lack of available personnel and accommodation make such an arrangement generally impracticable. The cost of caring for a child in a day nursery, though substantial, is considerably less, and should be remembered, however, that day-nursery care takes children out of the family circle. The question is further complicated by the present demand for women in industry. In a long-term policy, apart from national need, should the community as a whole provide nursery places and shoulder all or any of the cost to enable a mother to young children to work because she wishes to do so? On the other hand, should any woman be denied the opportunity, available to others, of arranging her life in accordance with her own wishes? There is the question, too,

possible loss to the community, one way or another, if a woman who is trained or skilled in certain work has to choose between that work and motherhood. For those women (and the number is probably not great) for whom a conflict exists between the claims and interests of motherhood and other work there is probably no completely satisfactory solution. A reasonable solution would seem to be that opportunity to work should be made available through nursery places, but that in such cases the mother, and not the community, should bear at least a substantial proportion of the cost, which the additional income would enable her to do without hardship.

#### d) Effect of Day-nursery Life on the Health and Well-being of Young Children

The aim stated at the outset, that every mother should be enabled to bring up her own children within the family circle in their earliest years, is based on the conception of the family as the natural biological unit of human society. It is also strongly supported by knowledge of the benefits in childhood of family life at its best, and of the disadvantages of community life at too early an age.

It is generally recognized that the rate of development of the human infant is such that it is not until some time between the ages of 2 and 3 years that he is ready for more than occasional contacts beyond the family circle. Before that time he is physically and emotionally dependent on his mother, and needs the security of home and family life. It is unnatural and biologically unsound to separate a child from his mother and his home for long periods until he has at least begun to develop his independence. Some infants may be able to adapt themselves fairly readily to surroundings that are essentially unnatural, but others will suffer psychological trauma. It is well known that it is the children between about 9 months and 2½ years who present the greatest difficulties to the staff of a nursery. Prior to that age the difficulties are not so obvious because the child for long periods is unaware of his surroundings and appears to require little beyond attention to his physical needs in the intervals between sleep. Even at this age the lack of true mothering and of breast-feeding is a real deprivation to the emotional life of the child, the results of which may be difficult to foretell. Looked at purely from the psychological angle, group care of young children away from their homes is surely desirable only if the home is such that fear and insecurity replace the normal trust and security of family life—and this is, in earliest childhood, comparatively uncommon even in homes that from other aspects may well be regarded as unsatisfactory.

On the physical aspect of health and well-being a good deal of evidence has accumulated recently which is tending to modify the belief, widely held during the war, that in general children could hardly fail to respond well to nursery life, with its obvious advantages of good food, rest, fresh air, and supervision. The report of an investigation by the Medical Women's Federation (1946), based on the findings of seventy-three independent medical observers scattered all over the country, showed that there was a much higher incidence of respiratory infection among children of all ages in wartime day nurseries than among children living at home and attending welfare centres, and that although there was an improvement in weight and physique of the older children in the nurseries, no such improvement was manifest in the children under 2 years of age. Moreover, the investigation showed that the higher incidence of respiratory infection was not accounted for by significant differences between "home" children and nursery children at the start of their nursery life.

A report based on the records of nursery children and welfare-centre children in Oxford (Allen-Williams, 1945)

showed similar findings; it also showed that infection tended to occur at an earlier age in nursery children.

A study of children in nurseries in Leyton (Menzies, 1946) revealed a high incidence of infection and unsatisfactory progress, especially in children under 2 years of age.

The report of a further investigation on behalf of the Medical Women's Federation (McLaughlin, 1947) records the findings in the examination, during a period of twelve months, of 557 day-nursery children and 641 children living at home, and shows that evidence of respiratory infection was two to eight times more common among the nursery children, that the higher incidence was manifest at all ages, and that the nursery children developed respiratory tract infection at an earlier age than did the "home" children. The results also showed that although the older children in the nurseries were heavier than "home" children in the same age group, this was not so in the age groups under 2 years. A finding of particular importance in this investigation related to measles, which was four times more frequent among the presumed susceptibles in the nursery group than in the home group. Moreover, the excess incidence in the presumed susceptibles was especially marked in the children under 18 months old (33.6% in the nursery group and 5% in those living at home)—an observation of great significance in view of the higher fatality rate of measles among younger children.

This accumulating evidence cannot be ignored. It has been suggested that even though infections in day nurseries are common, nevertheless the risk of serious ill-health is lessened, because day-nursery care leads to improved general physique and better resistance. There is at present no published evidence to support such a hypothesis. In fact, as has been stated, evidence shows that there is no improvement in general physique in the younger children, who are the ones most endangered by infection. It may be that the improvement in weight of older children gives grounds for expectation of improved resistance to serious ill-health, but at present proof is lacking. The children actually in a nursery are not a reliable criterion. Anything more than a mild manifestation of ill-health leads to exclusion of the child, and he may or may not return to the nursery. Those who are seen in a nursery are not the ones who have "stayed the course." Menzies (1946) reports that in the Leyton nurseries the records over a period of 3½ years showed that only 16% of the children who were admitted stayed in the nurseries until school age—and this at a time when there was every encouragement to mothers to leave their children in nurseries.

These considerations and evidence of the effect of group care on the emotional and physical health and well-being of young children have been reviewed at some length because it is realized that they conflict with a view that has been widely held—that day-nursery care is intrinsically a sound health service for children. There can be no doubt that for the younger children this is not so. For the older children there is still the increased danger of infection, but this may be somewhat counterbalanced by improved general physique and by the greater opportunity for mental development at any age when the child is ready for it, especially for those who might not otherwise have comparable opportunities.

The observations and investigations to which reference has been made relate to children in day nurseries, but there can be little doubt that they would apply to any congregation of young children, since group care inevitably increases the risk of the spread of infection. Nursery schools or nursery classes attached to primary schools (both of which cater for children of from 2 to 5 years) are being increasingly provided, and they may tend to be regarded primarily

from the educational standpoint. Due weight must, however, be given to the health considerations outlined above, and it is necessary to emphasize the need for continuous and skilled supervision of health and hygiene for children in nursery schools and classes no less than in day nurseries.

### Conclusion

To sum up, day nurseries are needed principally as a means of alleviating the effects of grave social disorders which make it impossible for many children to have anything approaching a healthy or happy home life. But it should be clearly realized that group care—on its intrinsic merits, and social considerations apart—is not a sound health measure for young children, particularly those under 2 or 3 years old.

It is the realization of this fact and the recognition of the home and family as the natural healthy social background for a young child that warrant the aim already stated—that every mother should be enabled to bring up her own children in health and happiness within the family circle in their early years. The social disorders that stand in the way of achieving this aim should be directly attacked, and the provision of day nurseries should be regarded mainly as an interim measure of alleviation until the attack is successful and home life in early childhood can be widely developed at its best.

## A POSSIBLE MODE OF ACTION OF PENICILLIN

BY

K. M. PANDALAI, M.Sc., Ph.D.

AND

MARIAM GEORGE

(From the Department of Biochemistry, Indian Institute of Science, Bangalore)

Among the many theories suggested to explain the mechanism of drug action the concept that drugs act by metabolic interference has gained much prominence. The antibacterial action of penicillin *in vitro* and *in vivo* appears to be primarily bacteriostatic, inhibiting the growth of the infecting organisms by preventing cell division and multiplication. This is probably achieved by interfering with some metabolic function in the early stages of bacterial development or by acting as an ineffective substitute for some essential metabolite which may have the nature of an enzyme or a vitamin, or even that of certain active groupings in the cell such as the SH group, the  $\text{NH}_2$  group, or a COOH group. Glucose utilization for energy production and cell synthesis is an inevitable metabolic reaction, and substances like nucleic acid, thiamine, riboflavine, nicotinic acid, tryptophan, uracil, etc., besides being essential growth factors in the case of typical parasites like *Staphylococcus aureus*, are also parts of the prosthetic groups of oxidation enzymes involved in cellular respiration. In order to elucidate the physiological characteristics of the antibacterial action of penicillin the influence of some of the above substances was studied, and the results obtained with nucleic acid, which is a major constituent of the bacterial cells, are recorded in this note. It may be added that Mellwain (1941) has demonstrated nucleic acid antagonism to the antibacterial action of the acridine derivatives, and Krampitz and Werkman (1946) suggest

that penicillin may interfere with the metabolism of nucleic acids or nucleotides in the case of *Staph. aureus*.

Twenty-four-hour broth cultures of *Staph. aureus* were used in one loopful in duplicated sterile culture tubes containing a total volume of 10 ml., including nutrient broth and the test substance added in requisite amounts. The tubes were observed after twenty-four hours' incubation at 37° C. and the turbidity in the tubes due to bacterial growth was measured.

TABLE I.—Showing the Influence of Penicillin and Nucleic Acid on the Growth of *Staph. aureus*

Penicillin Alone (Units per ml.)	Growth in Broth	Nucleic Acid Alone	Growth in Broth	Penicillin (Units per ml.) and Nucleic Acid	Growth in Broth	Control in Broth
0.3	—	1/2000	+++	0.3 } 1/2000 0.2 } 0.1 }	+	+++
0.2	—	1/5000	+++	0.3 } 1/5000 0.2 } 0.1 }	+	+++
0.1	+	1/10,000	+++	0.3 } 1/10,000 0.2 } 0.1 }	+	+++
0.05	+	1/20,000	+++	0.3 } 1/20,000 0.2 } 0.1 }	+	+++

Table I shows the remarkable fact that nucleic acid has no particular growth-promoting influence on the organism but is strongly antagonistic to the bacteriostatic action of penicillin. In the presence of added nucleic acid the penicillin either did not inactivate or side-track the cell nucleic acid or, even if it did, the organisms could still thrive on the external source of nucleic acid, thus nullifying the bacteriostatic effect of the drug. That penicillin bacteriostasis of *Staph. aureus* is reversible in the presence of added nucleic acid is clear from Table II.

TABLE II.—Showing the Reversibility of Penicillin Bacteriostasis of *Staph. aureus* by Added Nucleic Acid

Penicillin (Units per ml.)	Nucleic Acid added to Broth after 3 Hours	Nucleic Acid added to Broth after 6 Hours	Penicillin Control	Nucleic Acid Control	Control in Broth
0.1	1/1000 ++ 1/2500 ++ 1/5000 ++	1/1000 ++ 1/2500 ++ 1/5000 ++	+	+++ +++ +++	+++
0.2	1/1000 ++ 1/2500 ++ 1/5000 ++	1/1000 ++ 1/2500 ++ 1/5000 ++	—	+++ +++ +++	+++
0.3	1/1000 ++ 1/2500 ++ 1/5000 ++	1/1000 ++ 1/2500 ++ 1/5000 ++	—	+++ +++ +++	+++

+++ indicates very good growth. ++ indicates fairly good growth. + indicates scanty growth. — indicates no growth.

Organisms that were exposed to penicillin and became non-viable could actually be rendered viable by subsequent exposure to nucleic acid. It is interesting to note that a strain of *Streptococcus viridans* and a strain of *Bacillus subtilis* gave exactly similar results.

Nucleic acid thus appears to be of paramount importance for the growth and multiplication of organisms like *Staph. aureus*, *Str. viridans*, *B. subtilis*, etc. Penicillin probably acts by interfering in some way with one or more phases in the metabolism of the organisms which involve nucleic acid function. Probably penicillin forms inactive complexes with nucleic acids which aid in the utilization of the energy material essential to the nutrition of the parasite and when the inhibition is rendered reversible by nucleic acid addition the latter, besides making good the cellular needs, also helps to lower the effective concentration of penicillin, thus restoring the cells to a condition in which growth is again possible. Metabolic interference by penicillin in phases where nucleic acids play an important part

in cellular processes appears to be the prime factor in penicillin bacteriostasis. These studies are being pursued further.

We gratefully acknowledge our indebtedness to Prof. V. Subrahmanyam and Major K. P. Menon for their kind interest and helpful criticisms, and to the Council of Scientific and Industrial Research, under whose auspices this work is being carried out.

## Medical Memoranda

### A "Fishing" Story

Strange cases come our way from time to time in surgical practice, but I think that the following case is worthy of record.

#### CASE REPORT

A Malay villager was admitted to the Malacca General Hospital on Feb. 27, 1947, in a very distressed state, with laryngeal obstruction. There was a marked stridor and retraction of the intercostal spaces. He was throwing himself about on the stretcher and was very difficult to examine, and of course quite unable to give any history. This, however, was freely and willingly given by about six of his relations simultaneously. It appeared that an hour previously the man had been drawing in his net in a rice field. Holding up the edge of his net, he peered over to inspect his catch, whereupon a fish leaped out of the water into his mouth and disappeared down his throat. All efforts on the part of friends and relations to dislodge the fish proving fruitless, it was decided to bring him to hospital.

On examination the tail of a fish could be clearly seen over the base of the tongue. This was grasped in sponge-holding forceps; but traction only resulted in the tail coming off, making matters worse than ever. The body almost filled the pharynx. Palpation revealed the fact that the long spiked dorsal fin of the fish was extended and firmly imbedded in the posterior pharyngeal wall, which was fast swelling up, and the patient was becoming cyanosed. He was taken to the theatre, his struggles being controlled by 5 ml. of thiopentone intravenously, and a low tracheotomy was performed. Breathing through the tube having been established, it was found that his jaws were firmly closed and could not be opened. He was therefore deeply anaesthetized by open chloroform over the tracheotomy tube, and the mouth opened. By forcing an index finger down alongside the fish the finger-nail could just reach the gill. Then by a process of "bipolar version," one finger inside and one outside the pharynx, the fish was "turned" from "breach" to "vertex" and successfully delivered. There was severe laceration of the posterior pharyngeal wall, which was swabbed with flavine and left to granulate. The tracheotomy tube was removed on the second day and recovery was uneventful.

The fish, which measured 13 cm. in length and 8 cm. at the greatest circumference, is known in Malaya as ikan betok. It frequently leaves the water, and is credited with being able to climb a tree. The Malay villagers affirm that when one is fishing for ikan betok one should "not laugh but keep one's mouth shut." The accompanying photograph shows its approximate shape.

I am indebted to the Director of Medical Services, Malayan Union, for permission to publish this case.

R. M. B. LOWIS.

Acting Surgeon, Negri Sembilan, Malayan Union.

### A Case of Bilateral Syme's Amputation

The following case is published as a surgical curiosity rather than a recommendation for the revival of an obsolescent operation. It was of interest to me because, although I had never seen Syme's amputation performed and could not obtain advice as to the form of surgical boot necessary for the stump. I was able to get a man walking on two stumps with crude boots made by a local shoemaker.

#### CASE REPORT

An African adult male was brought into Tanga Hospital on Sept. 28, 1945, with a history of his foot having been bitten by a wild cat. He had been living for many years in a leprosy settlement maintained by the Universities Mission to Central Africa. On examination his general condition was good and he had a cheerful disposition, remarkable in a destitute person afflicted with a crippling disease. The left foot had been bitten through, leaving the metatarsals projecting from a mass of gangrenous muscle. The right foot was in the slow process of destruction by necrosis and ulceration often associated with leprosy. The fingers of both hands were stunted and deformed as a result of a similar process in the past. The wound was dressed daily with eusol and soon became clean. The metatarsals separated as sequestra, and a smooth granulating area covered the proximal half of the foot. On Nov. 21 a Thiersch graft was applied to this area and took well. It was hoped at first that it would be possible to get him walking on this stump, but the skin was too thin and soon ulcerated over bony points in contact with the ground. Moreover, the other foot was painful, and even with the aid of crutches weight-bearing was almost impossible.

On Feb. 1, 1946, I performed Syme's amputation of the right foot, as the sinuses showed little signs of healing. The head of the third metatarsal on dissection was found to be lying as a sequestrum in a cavity of brown pus. The wound healed by first intention and the patient was highly pleased with the result. The stump seemed so much more satisfactory than the skin-grafted left foot, complete with calcaneus and mid-tarsal bones, and I decided that a second Syme's amputation was indicated. On May 27 the left foot was amputated. Less skin was available to make a good flap, and part of the graft had to be incorporated in the line of incision. The stump healed after slight sepsis, but was not quite so satisfactory as the first.

Throughout his period in hospital he was encouraged to exercise his legs, and he had no contractures of knees or hips. He took part in our daily ward gymnastics to the strains of "Colonel Bogey" and "Blaze Away" played on the hospital gramophone. It was not until August, 1946, that a physiotherapist was sent to Tanga and systematic skilled attention became available. On Aug. 15 the patient first stood on his bare stumps and took a few steps with assistance in the ward. Meanwhile the problem of suitable boots had been under consideration, and at last I persuaded an Indian shoemaker to attempt something which finally looked like a pair of elephant hoofs (see photographs). These boots were fitted on Sept. 2.

FIG. 1

FIG. 2

FIG. 1.—After amputation, showing also the improved "boots."

FIG. 2.—The patient ready for walking.

For the first time for 13 years, one of which was spent in hospital, the patient walked unaided for a short distance. This was increased daily under the supervision of the physiotherapist. Unfortunately, in a few days the left stump became chafed by the rough leather inside the boot and threatened to ulcerate where the scar was close to the bone edges. The physiotherapist knitted him footless socks, and cotton-wool padding was inserted to protect the stump. He was then able to walk for about a quarter of an hour without fatigue, though he was unable to stand alone.

Shortly afterwards I was transferred from Tanga to a distant part of the country and have not seen him since. I last heard that he was progressing slowly and that it was difficult to persuade him to stay in hospital. What his ultimate fate will be it is impossible to foretell, but I think the immediate result is as satisfactory as could be expected. Where conditions of life are primitive there is still a place for primitive methods in surgery.

I wish to thank Miss Q. C. Brown, physiotherapist, for her assistance and the Director of Medical Services, Tanganyika, for permission to publish this case.

L. H. CANE, M.B., B.Ch.,  
Medical Officer, Tanganyika Territory.

### POPULATION POLICY OF AUSTRALIA

*Women and Children First! An Outline of a Population Policy for Australia.* By Victor H. Wallace, M.D., F.R.C.S. (Pp. 350, 15s.) London: Geoffrey Cumberlege (Oxford University Press).

In a novel the scene and period of which were South-eastern Europe and post-war (the first German war) the author remarked that the number of banks in a city seemed to vary inversely as its prosperity. The number of books, papers, committees, and royal commissions considering the problem of population rises steadily as the birth rate declines. Dr. Wallace inevitably says many things which have been said before and accepts some postulates which can be challenged. It may be economically true that the population of Australia could be increased from its present 7.4 millions to 30 millions without harm to the standard of living; it is certainly true that this result cannot be achieved at the present rate of natural increase, and probably true that immigration is a very poor substitute for natural increase. But, as Sir David Rivett remarks in the "Foreword," it is not certain that the average individual of the 30 millions would be happier than the average in the present 7.4 millions. That, however, is another story.

Dr. Wallace sets out to explain how it might be practicable to reach a population of 30 millions. The special interest of his book is that he approaches the problems from the standpoint of an experienced medical practitioner. His contributions to new knowledge are (a) a study of the motives leading patients to seek his advice on contraceptive methods; (b) an informed criticism, from the medical point of view, of measures proposed, or which might be proposed, to stimulate growth of population. Dr. Wallace had kept records of his patients; he circularized some he had seen in recent years and personally questioned. When he had received 530 replies he closed the statistical inquiry. Dr. Wallace is not, and does not claim to be, a statistician. On the data provided in his book no statistician could judge whether Dr. Wallace's patients were a random sample of women desiring to limit their families, or even whether the patients who answered his questions were a random sample of Dr. Wallace's patients. Certainly some of the answers quoted (for instance No. 8 on p. 49) indicate a power of literary expression above the English average. But there is such a thing as common sense; we have no doubt that the author has more than an average share of that not very common quality and accept his sample, or selection, as instructive.

The first thing that strikes a cockney medical reader is that what these Australian women write about is what he hears every day from patients or friends: the difficulty of obtaining suitable accommodation, the aversion of landlords and of neighbours in flats to children, the impossibility of securing domestic help, the wearisomeness of shopping. At first youthful memories of books about bushrangers, billies, and gold-digging make this seem very odd; but if the reader is a statistician, or even a user of Whitaker's *Almanack*, he notes that of the 7.4 millions in Australia 3.6 millions live in the six State capitals (2.5 millions in the two cities of Sydney and Melbourne) and realizes that Dr. Wallace's patients have much the same problems to solve as Greater Londoners. Dr. Wallace's statistical analysis is not minute, but simple reading of his extracts from replies confirms the opinion of most medical men in this country that selfish love of pleasure is *not*, as some self-satisfied moralists preach, the prime factor of a declining birth rate.

And the remedies? Dr. Wallace's views on the medical care of pregnant women and on the organization of maternity clinics and community centres would be endorsed by most British doctors. When he turns to the general economic and social problems what he says is always sensible, but medical readers may possibly feel that neither he nor they are expert judges. He makes it *quite* clear that in Australia—as of course in Great Britain—State Socialism (practised by all political parties) has not gone far in reducing the heavy financial burden upon the parents of large families who wish their children to enjoy at least as much of the intellectual and material pleasures of life as they themselves had. He reckons (to take only one item)

that the average cost of having a baby is approximately £64. To this the State contributes £16. There is some irony in the reflection that, if his analysis is right, the only State which does make a very substantial contribution to the cost of bearing and rearing children is Soviet Russia. Soviet Russia, it may be added, also encourages child-bearing and rearing by the award of "Honours," and Dr. Wallace thinks this psychologically sound. There is in Soviet Russia an Order of the Glory of Motherhood with three classes to be awarded to mothers who have reared 9, 8, or 7 children respectively. If rumour speaks truly, "Honours" are sometimes awarded in this country for less obviously valuable services, but one may doubt whether the Order of the British Empire could be so allocated as to encourage the birth rate. However this may be, Dr. Wallace has written a book which any doctor could read with advantage. Even those sections concerned with purely Australian problems are valuable to an English reader, for they teach him something about a great Dominion which he ought to know and probably does not.

MAJOR GREENWOOD.

### TEXTBOOK OF HAEMATOLOGY

*Principles of Hematology.* By Russell L. Haden, M.D. Third edition, thoroughly revised. With 106 illustrative cases, and 167 illustrations, including 173 original photomicrographs and 95 original charts and drawings. (Pp. 366; illustrated. 25s.) London: Henry Kimpton. 1947.

We welcome a third edition of this book, for it is more suitable for the student than any of the other current textbooks of haematology. The author's approach is physiological and quantitative, and he teaches the student to think of the patient as a whole and not merely of blood pictures. The text is simple and the diagrams, which Dr. Haden has tried and perfected by long years of lecturing, are ingenious and instructive. He includes some very good photomicrographs and some striking examples of a method of representing red cells in bas-relief. Dr. Haden first describes the normal haemopoietic system and the standard methods of blood examination. He gives a good account of the normal haemoglobin value and the meaning of "100% haemoglobin." In the next part of the book he discusses the mechanisms underlying the various blood disorders and describes the common forms of the latter. The final section consists of illustrative case histories. The principal new material in this edition is an account of the methods and results of sternal puncture.

The author seems to have omitted to revise several points. It is no longer believed that the pyloric glands in man secrete Castle's intrinsic factor: it is now thought to come from the fundus. Most haematologists would deny that the megaloblast is a normal stage of erythropoiesis in extrauterine life, and most would estimate the life of the red cell to be 100 rather than 25 to 30 days. Myelosis is a synonym for myeloid leukaemia, and in describing the production of agranulocytosis by amidopyrine it would therefore be better to speak of toxic myelopathy than of toxic myelosis. It is bad luck that this edition was prepared before the recent work was done on folic acid and the chemotherapy of leukaemia, for the new remedies allow a more truly physiological interpretation of treatment than has hitherto been possible.

L. J. WITTS.

### THE CORONER

*Sir John Jervis' on the Office and Duties of Coroners.* By W. B. Purchase, M.C., M.B., D.P.H., Barrister-at-Law. Eighth edition. (Pp. 350, 30s.) London: Sweet and Maxwell.

Sir John Jervis brought out the first edition of this famous textbook in 1829. The last edition, published in 1927, was edited by the late Mr. F. Danford Thomas. Since then, in spite of much public discussion and a departmental committee, there has been no alteration in the law except for the temporary provision dispensing with coroners' inquests on air-raid deaths. Nevertheless, Dr. Bentley Purchase's eighth edition of this book is welcome, for he has had many years' experience both as a London coroner and as honorary secretary of the Coroners' Society of England and Wales.

The last three editions were written as an extended commentary on the wording of the relevant statutes—a form common in legal textbooks. Dr. Purchase has departed from that style,

with its unnecessary complication and repetition, and has arranged his material in narrative form, divided according to the various aspects of the subject. His first chapter, on the classification and appointment of coroners, reveals a surprising variety. All the High Court Judges are coroners *ex officio*, though none of them has ever been known to hold an inquest. There are still a number of franchise coroners, appointed by various corporations, lordships, universities, and other communities with this traditional right. The King's Coroner and Attorney holds an interesting historical sinecure; the Coroner of the King's Household has jurisdiction within the palaces. Apart from these, most coroners are, of course, appointed by local authorities under statute. Dr. Purchase deals fully with qualifications and disqualifications, jurisdiction, and duties, including the curious duty of inquiring into the circumstances of treasure trove. In his chapter on the report of deaths to the coroner he follows the traditional rule that every person about the deceased has a duty (unless the duty is imposed upon some particular person) to give notice to the coroner, his officer, or an officer of police. He admits that there is no sanction for the enforcement of this duty, but does not comment on the interesting opinion given by Sir Roland (then Mr.) Burrows, K.C., at the end of 1943 and discussed in the *Journal* (April 8, 1944, p. 498) denying that such a duty exists in law. He states that the medical practitioner has a social or moral obligation, which has become a well-founded custom, to report deaths to the coroner in suitable cases apart from his duty, which Dr. Purchase holds to be absolute, to issue a certificate if he has attended the deceased during his last illness, even though he cannot state the cause of death. In cases where the practitioner knows or suspects that the death is connected with a crime, Dr. Purchase quotes with approval Mr. Justice Avery's well-known charge to the Birmingham Grand Jury at the December Assizes in 1914, declaring that a practitioner with such knowledge should communicate with the police. That particular case was one of alleged criminal abortion, and medical and legal opinion on the judge's ruling has continued to be sharply divided until the present day. In his section on death under an anaesthetic he is impartial and does not support those coroners who would press anaesthetists and hospital authorities for notice and information which they are not strictly obliged by law to give. The book abounds with clear and accurate information and omits no point of substance. Half the volume consists of an appendix containing statutes, regulations, circulars, and forms, as well as a note on the emergency provisions in force during the war.

D. H. KITCHIN.

### THE BRUNNER GLANDS

*The Duodenal Glands of Brunner in Man, Their Distribution and Quantity.* By Erik Landboe-Christensen. Translated from Danish by Hans Andersen, M.D. (Pp. 267; illustrated, 20s.) Copenhagen: Einar Munksgaard, London: Geoffrey Cumberlege (Oxford University Press). 1944.

Studies on the cells of the gastro-intestinal tract by precise quantitative methods are few in number. Exact knowledge of their function, variation in number and distribution, and modifications in disease is still relatively scanty. The author of this monograph set himself to answer one question: What is the distribution and glandular density of the Brunner glands in a representative section of the population? We may say that he has succeeded in answering it. His technique was a modification of that used by Malfoe and Hellman for the quantitative estimation of the lymphatic follicles in the intestine. He has thus accurately mapped out the distribution and glandular density in 53 patients, none of whom had duodenal scarring or ulceration. His results show the relative constancy of the distribution and a range of variation not appreciably altered in old age. The findings should form a valuable basis for future work on the exact physiological functions of these glands and their variation in disease.

W. T. COOKE.

Messrs. William Heinemann (Medical Books), Ltd., 99, Great Russell Street, London, W.C.1, inform us that they are the agents in this country for *Clinical Methods of Neuro-Ophthalmologic Examination*, by Alfred Kestenbaum, which was reviewed in the *Journal* of July 12 (p. 58). The English price of the book is 25s.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*The Chemical Activities of Bacteria.* By E. F. Gale, B.A., Ph.D. (Pp. 199. 8s. 6d.) London: University Tutorial Press. 1947. An elementary introduction for students of biochemistry and bacteriology.

*Vital Statistics and Public Health Work in the Tropics.* By P. Granville Edge, O.B.E., D.Sc. 2nd ed. (Pp. 265. 15s.) London: Baillière, Tindall and Cox. 1947.

Discusses the application of statistics under conditions peculiar to the Tropics.

*Office Immunology Including Allergy.* Edited by M. B. Sulzberger and R. L. Baer. (Pp. 420. 36s.) London: H. K. Lewis. 1947.

A survey of allergy and immunology for the general practitioner.

*A Way of Life for the Handicapped Child.* By Eirene Collis, M.C.S.P., M.A.O.T. (Pp. 183. 10s. 6d.) London: Faber and Faber. 1947.

The author describes her methods of treating cerebral palsy.

*Aids to Practical Nursing.* By Marjorie Houghton, S.R.N., S.C.M., D.N. 5th ed. (Pp. 364. 5s.) London: Baillière, Tindall and Cox. 1947.

An introduction to nursing for the student nurse; with illustrations.

*Unwanted Child.* By Eustace Chessier, L.R.C.P.&S.Ed. (Pp. 152. 12s. 6d.) London: Rich and Cowan. 1947.

An account of the psychology and family background of unwanted children.

*Diagnostic Examination of the Eye.* By Conrad Berens, M.D., F.A.C.S., and Joshua Zuckerman, M.D., C.M., F.A.C.S. (Pp. 711. £4 10s.) London: J. B. Lippincott Company. 1946.

Describes a step-by-step procedure for examining the eye; with many illustrations, some in colour.

*Surgical Treatment of the Soft Tissues.* Edited by F. W. Baneroff, M.D., F.A.C.S., and G. H. Humphreys, M.D., Sc.D., F.A.C.S. (Pp. 520. £4 10s.) London: J. P. Lippincott Company. 1946.

Includes surgery of the subcutaneous tissues, hernias, blood vessels, and the treatment of burns.

*1946 Year Book of Endocrinology, Metabolism, and Nutrition.* Edited by W. O. Thompson, M.D., and Tom D. Spies, M.D. (Pp. 573. 21s.) London: H. K. Lewis. 1947.

Includes recent reports on thiouracil, radio-active iodine, and substances related to desoxycorticosterone.

*The Essentials of Materia Medica, Pharmacology, and Therapeutics.* By R. H. Micks, M.D.(Dubl.), F.R.C.P.I. 4th ed. (Pp. 399. 18s.) London: J. and A. Churchill. 1947.

This edition includes new material on anaesthetics and narcotics, tubocurarine, the antibiotics, benadryl, folic acid, and paludrine.

*Recent Advances in Endocrinology.* By A. I. Cameron, C.M.G., M.A., D.Sc.(Edin.), F.R.I.C., F.R.S.C. 6th ed. (Pp. 443. 21s.) London: J. and A. Churchill. 1947.

Includes an account of a case of Addison's disease successfully treated, and considers thiouracil and synthetic iodo-proteins.

*Handbook of Diagnosis and Treatment of Venereal Diseases.* By A. E. W. McLachlan, M.B., Ch.B., D.P.H., F.R.S.Ed. 3rd ed. (Pp. 375. 15s.) Edinburgh: E. and S. Livingstone. 1947.

Revisions include the discussion of penicillin therapy and its limitations, as well as oil-wax vehicles.

*The American Sanatorium Association.* By Lewis J. Moorman, M.D. (Pp. 72. No price.) New York: National Tuberculosis Association. 1947.

A brief historical sketch of the Association, with photographs.

*Textbook of Pathology.* By E. T. Bell, M.D. 6th ed. (Pp. 910. 50s.) London: Henry Kimpton. 1946.

This edition includes fuller discussion of vitamin deficiencies and tropical diseases.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 9 1947

## PLANNING AND WORLD POPULATION

Mr. Churchill may have wished to make our flesh creep when he suggested that starvation might lie ahead of us, but his observation was a useful reminder that for a long time now the people of Britain have been unable to feed themselves from home-grown produce.

When in 1798 Malthus<sup>1</sup> first propounded his theory that the increase of population would outstrip the food supply, Western Europe was just embarking on the industrial revolution. For the next hundred years manufactured goods produced by large-scale industry were sold to an underpopulated world possessed of enormous agricultural potentialities which could be exploited to provide cheap food for the ever-increasing number of European factory workers. Thus in the light of nineteenth-century economics Malthus was a false prophet. To-day his theory commands more respect.

When in 1940 the British Parliament passed the Colonial Development Act the more backward dependencies of the Empire were at last able to obtain money for schemes which were calculated to raise the standard of living of millions of people by giving them better housing, better water supplies, and improved medical facilities. By the provision of these amenities, among other things, the high infant mortality will be materially affected. The newer insecticides and paludrine will reduce deaths among young children from malaria; penicillin and the sulphonamides will prevent the deaths of young adults from pneumonia, while the same drugs will materially reduce the incidence of syphilis and gonorrhoea, those potent causes of abortion and sterility. Thus merely by chemotherapy alone, even if unsupported by universal education and intensive economic development, a considerable increase should occur in the population of the Tropics. When chemotherapy is backed by the various ameliorative schemes which Colonial Governments have now so eagerly put forward the increase in population may well be as great as that seen in England and Wales, where the population increased from 8,892,536 in 1801 to approximately 40,000,000 in 1931. Similarly, the population of India rose by 83,000,000 between 1921 and 1941, the total now being about 400,000,000; this increase occurred despite some 1,000,000 deaths a year from malaria alone. The highest recorded growth per annum was between 1931 and 1941, when it was 1.2%. An annual increase of 1% per annum means, it may be noted, that the population doubles itself in about 70 years, while if the increase is 1.5% per annum the population doubles in about 46

years. The views in regard to the effects of this phenomenal increase in the population of India so ably put forward by Sir John Megaw<sup>2</sup> in this *Journal* have been fully corroborated by the recent comprehensive *Report of the Indian Health Survey and Development Committee*<sup>3</sup> under the Chairmanship of Sir Joseph Bhose. Though they "recognize that the advance of science, careful planning and the concentrated effort on the part of the community to develop the country's resources may make possible the support of a largely increased population on even a better standard of living than that which exists at present," they realize that "such measures can constitute only a temporary expedient, because a limit to economic productivity will be reached sooner or later, and uncontrolled growth of population must outstrip the productive capacity of the country."

A similar high rate of increase is probable in many parts of Africa. The Social and Economic Council of the Union of South Africa in their second Report<sup>4</sup> stated that for the period 1943-55 they have used as an estimate for planning purposes an increase in the African population of 2.3% per annum. Even though from a census taken in 1946 the actual increase for the decade appears to be only 1.58% per annum, this rate is greater than any hitherto recorded all-India figure. In the case of East Africa Paterson,<sup>5</sup> after careful consideration of all the relevant facts from Kenya, Uganda, and Tanganyika, comes to the conclusion that the rate of increase is now, or will soon be, about 1.5% per annum and that it is not improbable that within a few years the rate may be nearly 2% per annum, in which case the native population will double itself in 35 years' time.

If in these various countries of Asia and Africa this huge increase in population has occurred in the past with comparatively little help from medical science, what may be expected in the next decade, now that medicine has been armed with far more powerful weapons for reducing the death rate? There are four checks on the growth of population: war, epidemic disease, famine, and voluntary control of the birth rate. War with its atomic bombs and rockets will, unless it is prevented, take its toll largely from the highly industrialized urban populations of Europe and America; epidemic disease can with modern medicine and sanitation be localized and controlled. Famine and voluntary restriction of births are the two remaining factors. Anyone who has travelled extensively in India and in Africa must have seen how closely in many areas population is already pressing hard on the means of subsistence. The fertility of the soil is already becoming exhausted because of the absence of fallow, while the thin layer of fertile soil, deprived of its vegetation by the cow and the even more ubiquitous goat, is being washed away by tropical rains. Even if, as the Governor of Kenya<sup>6</sup> suggests, there is a radical reorganization of present systems of land use and agrarian methods, an

ignorant man with a hoe, his wife, and his children are a totally inadequate foundation for an enlightened state of society, a high standard of living, and elaborate social services. Much less is such a family a secure foundation for the production of goods which can pay for the import of food from the few agricultural countries still possessed of an exportable surplus. There remains the hope that in tropical countries a rise in the standard of living may result in a fall in the birth rate such as is now occurring in Western Europe and America. Even if such a fall did begin at once it would rapidly result in the Tropics also in a great increase in the number of old and non-productive people who would have to be supported by the agricultural work of their children. It is doubtful, however, whether either in Asia or in Africa the birth rate will fall within a reasonable period in the face of prohibitive religious beliefs which form a fundamental part of the indigenous cultural pattern. Yet unless the birth rate falls in relation to the death rate and the population problem is solved much talk about colonial development and welfare is, to use an American expression, "whistling in the wind."

## RECENT AMERICAN WORK ON POLIOMYELITIS

The present high prevalence of poliomyelitis in this country lends special interest to reports of recent work in the U.S.A. Workers in Baltimore,<sup>1</sup> using the Lansing mouse-adapted strain in rhesus monkeys, have shown that after intracerebral inoculation the virus can be found in the spinal cord on the day before paralysis at the time when histological lesions are first demonstrable. The concentration of virus is maximal within the next day or two and then falls rapidly. The concentration varies with the stage of the disease rather than with the extent of paralysis. Another Baltimore paper<sup>2</sup> shows that in vaccinated monkeys with high serum antibodies there is no antibody in the cerebrospinal fluid, the anterior horn cells, or in the visual cortex. In monkeys with paralysis resulting from intracerebral inoculation the converse is observed: antibodies are present in the anterior horn cells and the medulla where the virus has multiplied, and not in the visual cortex or, except sometimes in small amounts, in cerebrospinal fluid or serum. The antibodies appear eleven to sixteen days after paralysis and persist or even increase for four or five months at least. These antibodies in susceptible parts of the central nervous system seem to be responsible for immunity, and immunity to paralysis in man may be due to their presence after invasion of the central nervous system without paralysis. Prophylactic inoculations should, however, aim at producing high serum antibody levels, as these have been proved<sup>3</sup> to protect monkeys against intracerebral inoculations. Unfortunately the development of an effective vaccine for use in man is not yet in sight, because it would be dangerous to use the necessary large amounts of live virus and because human strains differ immunologically

from one another and from the Lansing and monkey-adapted strains. This aspect is dealt with in studies at Yale<sup>4</sup> of subclinical poliomyelitis in chimpanzees in which immunity was produced to a homologous but not to a heterologous strain.

From Yale also there is an account<sup>5</sup> of poliomyelitis in Japan. Large epidemics had not been noted there till 1939, and the disease was thought to be uncommon. Yet the presence of a high endemic level was shown by an average annual mortality from 1923 to 1943 of 7.6 per 100,000, which is not much lower than the figure of 8.9 for the same period in the U.S.A. The presence of virus was also shown by a high incidence of paralysis in American troops in Japan. The age incidence in Japan is highest in the 0-5 age group, as it was when large epidemics of poliomyelitis first occurred in Sweden, the U.S.A., and Australia. A marked increase in the proportion of cases in the 5-15 age group has occurred in cities in these countries since 1930. The change is well shown by figures<sup>6</sup> for successive epidemics in New Haven, Connecticut. It was noted that in each epidemic the highest attack rates were in wards on the perimeter of the city and in nearby towns. No one ward was consistently attacked more severely than others, though rates were higher in wards adjacent to those heavily attacked in previous epidemics.

In a review<sup>7</sup> of the work on these and other problems in the epidemiology of poliomyelitis Sabin, who has been prominent in isolating virus from faeces, declares that spread occurs from faeces and not from the pharynx. In consequence he advises the use only of those control measures which will prevent transmission of the virus from contaminated faeces. He adds that control measures are not likely to check an epidemic though they may prevent the infection of a few persons who might otherwise be paralysed. However, other investigators<sup>8</sup> in the U.S.A. have stressed the importance of spread from the pharynx, and a valuable discussion<sup>10</sup> of the probable mode of spread led to the conclusions that nothing in the epidemiology of the disease is incompatible with spread from the pharynx and that spread may occur both from pharynx and faeces.

## INTERPRETATION OF CHEST X RAYS

Many methods of investigation depend on personal judgments which often reveal a lack of consistency in classification between different observers and in one observer's consecutive grading of the same group. The clinical assessment of nutrition in children is a well-known example of this difficulty. Variations in judgment have also been shown in haematological and other studies. A team<sup>11</sup> working for the Veterans Association in America has recently demonstrated similar discrepancies in the assessment of x-ray films of the chest. In an attempt to determine the relative effectiveness of various techniques, 1,256 men had films taken by four different methods: "a 35 mm. photofluorogram, a 4 by 10 in. (10 by 25 cm.)

<sup>1</sup> Radian, D., and Cumberland, M. C., *Amer. J. Hyg.*, 1947, 45, 226.

<sup>11</sup> Birken, C. C., *et al.*, *J. Amer. Med. Ass.*, 1947, 133, 359.

stereo-photosluorogram, a roentgenogram on a 14 by 17 in. (35 by 42.5 cm.) paper negative, and a conventional 14 by 17 in. celluloid film." In each case the films were taken within a few minutes of each other. They were then assessed by five experts who before the investigation had collaborated in an attempt to reach some uniformity of nomenclature.

Comparison of the interpretations of the films by the five radiologists showed varying inconsistencies. The number of the full-size celluloid films found positive for tuberculosis varied from 59 to 100; altogether 131 films were described as positive. All five agreed that the film was positive in only 27 cases. Four were in agreement on 17 films, three on 23, and in 47 cases only one observer described the film as positive. Further individual comparisons showed that from one-third to one-half of the films described as positive by one reader were negative according to the others. The radiologist with the smallest group of 59 positives had 31, 29, 37, and 14% of his positive films described as negative by the other four. The proportion of another reader's 100 positives labelled negative by the other experts varied from 42 to 50%.

The failure of the same individual to be consistent in his judgment was even more astonishing than the variation between different radiologists. All the films were assessed for a second time at a later date by the same five readers. The proportion of first positives regarded as negative on second reading by the same expert varied from 7 to 41%, and the proportion of the second positive readings which had been called negative on a first reading ranged from 6 to 19%. The radiologist who had 59 positives originally found an additional 23 on his second assessment, but missed 4 of his own first positives.

As might be expected from the variations shown by the individuals, a comparison of the four techniques gave large differences for the same reader. The one with 59 positives on the large celluloid film called 27, 30, and 24% of these positives negative when using the other three techniques. It seemed that each of the four methods had the same degree of efficiency, since at the second assessment all five readers missed almost the same number of cases in each of the four types of film. When a majority opinion was taken there was still a considerable discrepancy. Of the full-size celluloid films 61 were positive in the opinion of three or more readers but 10, 11, and 10% of the same cases were described as negative by three or more readers when the other three types of film were used. An attempt was then made to compare the relative efficiency of the four techniques by means of a total score. Since each person in the inquiry had four films assessed by five radiologists there were 20 verdicts for each individual. Of the 1,256 cases 994 had 20 negatives; 101 had only one positive; reading out of the 20; 21 cases had all 20 readings combined and 62 had an assessment from all techniques combined of 11 or more positives. In this last group the total number of positives recorded for each of the four methods were 259, 259, 259, and 250, out of a possible 310 (5×62) by any one technique. This analysis suggested that all four techniques were equally likely to pick out the cases requiring further study. The small-film techniques both gave a larger proportion of over-reading. Thus out of 101 cases with only one positive 46 were read on the 35 mm., 32 on the 4 by 10 in., 13 on the paper negative, and 10 on the 14 by 17 in. celluloid film. A similar order of technique was shown by the other small positive values.

This analysis showed that the various techniques were probably equally efficient. On the full-size celluloid film some useful supplementary detail appeared in a small number of cases. The differences between interpretations

and techniques were due to a large extent to the failure of a radiologist to be consistent. Since mass radiography is being used increasingly often, these discrepancies need serious consideration if efficient screening of early cases of tuberculosis is to be attained. It seems essential that more than one radiologist should examine the films and that any case which one expert describes as positive or suggestive should be referred for further investigation.

## RELIEF OF ANURIA

Many therapeutic claims based on single case records fail to withstand close analysis, either because essential data are lacking or because a multiplicity of therapeutic measures were used simultaneously. This applies particularly to measures undertaken to relieve anuria. The latter error was understandable when anuria was a desperate condition. The clinician knew that if the diagnosis had been made late he had at most three more days before a fatal outcome was to be expected. Life was too short and uncertain for art to be long. Diuretics like lactate, bicarbonate, caffeine, digitalis, sodium sulphate, and salyrgan were combined with procedures such as decapsulation, splanchnic block, or high spinal anaesthesia, often all in one unfortunate patient.

Recent advances have made it possible to view the onset of anuria more calmly. Both the artificial kidney devised by Kolff<sup>1</sup> of Kampen, in Holland, and the peritoneal lavage used by Fine<sup>2</sup> and his colleagues at Harvard allow us to prolong life by dialysing out of the circulating blood those substances responsible for uraemia. Neither of these methods, so far as we know, improves kidney function, although that is a possibility; they merely allow a longer period for natural or artificial restoration of renal function. As a rule, five hours on the artificial kidney will give a respite of two days. Peritoneal lavage is a slower procedure which, although technically easier, has more formidable complications, as has been pointed out by Fine himself.<sup>3</sup> The usefulness of both procedures has been confirmed in this country and it should now be possible to attack the fundamental problem of the anuria itself. Perhaps the most important fact we already know about anuria is that it has many and different causes and that many cases remain completely unexplained. Labels such as "reflex anuria" or "renal anoxia" are of little value. Even in anuria due to a single cause, such as mismatched transfusion, some patients will die and others will recover without, with, or despite treatment. Advocates of a particular line of therapy will always find reasons for other people's failures: this measure was applied too early or too late, too vigorously or too gently, for too short a time, or without the right sort of adjuvant treatment. Only rarely are exact criteria used. One such rarity is the record by Talbot and his colleagues<sup>4</sup> of a unilateral decapsulation in a case of mismatched transfusion. The effects of this measure were observed by ureteric sampling and intravenous urography.

Criteria by which to judge the efficacy of these measures are comparatively easy to lay down when a proceeding can be carried out on one of a pair of kidneys—e.g., decapsulation, sympathectomy, or splanchnic block. They are far more difficult to establish for procedures affecting both kidneys—diuretics, spinal anaesthesia, or bilateral decapsulation. Reliance must then be placed on a close temporal relationship between the procedure and the diuresis, if any.

<sup>1</sup> *De kunstmatige Nier*, 1946 (abbrev. English version: *Artificial Kidney*).

<sup>3</sup> *Lancet*, 1947, 1, 120.  
<sup>4</sup> *New Engl. J. Med.*, 1942, 226, 228.

This involves a careful measurement of the rate of flow of the urine before and after, hourly or even half-hourly. Unless there is an immediate response, the chance that any later diuresis is due to coincidence alone becomes much greater. If failures were published, or even remembered, it seems probable that only a very small proportion of cases would ever be shown to "respond" to these measures. It would be interesting to know what this fraction is, and even more interesting to know how many of such cases recover without treatment. It seems improbable, however, that therapeutic scepticism will ever be sufficiently widespread to make this latter category large enough to treat statistically.

### TOXIC EFFECTS OF MERCURIAL DIURETICS

The use of "salyrgan" as a diuretic is now widespread, and, the patent rights having expired, it has been included in the *British Pharmacopoeia* under the name of mersalyl. The official name indicates that it is a compound of mercury, and in view of the fact that mercury can be toxic it is surprising that mersalyl has maintained, in the main, so consistently good a reputation. The well-known German authority Volhard,<sup>1</sup> reviewing mercurial diuretics, said that for the treatment of the chronically failing heart the use of salyrgan, usually combined with strophanthin, had become indispensable; giving it weekly for many months he had never seen undesirable effects and had usually obtained entirely satisfactory results. Many similar statements have been made on its freedom from danger.

That an inherently toxic substance will eventually be found to cause toxic effects is, however, a reliable rule, and recently Oppikofer and Fehrenbach<sup>2</sup> published a paper on ulcerative mercurial stomatitis and necrosis of the jaw resulting from the use of the mercurial diuretics (salyrgan, "esidrone"). Esidrone was introduced by Ciba in 1938. The usual dose of esidrone, 2 ml., contains 44 mg. of mercury as compared with 76 mg. in 2 ml. of salyrgan. The signs of poisoning recorded by these authors are typical effects of mercury. They were observed in six patients: in five stomatitis with ulceration; in three necrosis of either the upper or the lower jaw or both; in two mercurial angina with ulceration; and in two mercurial dermatitis. In one patient salyrgan was to blame, in a second salyrgan and esidrone together, and in four patients esidrone. The doses were not excessive. The worst case was that of a man of 61, suffering from cardiac oedema, who was treated with about 20 injections of salyrgan over several months. He developed severe dermatitis and stomatitis, with necrosis of the upper jaw. When the salyrgan was stopped the dermatitis and stomatitis cleared up, but a serious jaw defect remained. Six months later the mercurial stomatitis flared up again, this time in the lower jaw, and he bled from the lingual artery.

The Swiss authors of this paper evidently know nothing of BAL (dimercaptopropanol) which was introduced by Peters, Stocken, and Thompson<sup>3</sup> during the war as an antidote to arsenical poisoning, and which has been shown<sup>4</sup> to be equally effective in mercurial poisoning. BAL is not yet generally available, though it has been supplied to V.D. clinics on application to the Medical Research Council. It will soon be in commercial production. BAL combines with mercury in the body and the combination is rapidly excreted. A patient receiving mersalyl will show, as the earliest sign of poisoning, excessive salivation. When

this occurs mersalyl should be withheld and BAL given by intramuscular injection. It is interesting to note that even the acute forms of mercury poisoning can be arrested by BAL. Long and Farah<sup>5</sup> have shown that the sudden failure of the heart which occasionally occurs when mersalyl is given intravenously can be overcome by the intravenous injection of BAL, but recovery of course occurs only when BAL is given without delay. Acute heart failure from mersalyl very rarely occurs if it is given by intramuscular injection. Since the diuretic effect is intended to be of several hours' duration at least, this route is the more rational.

### BLOOD GRAVITY AND HAEMOGLOBIN

The need for the control of intravenous infusion in war injuries led the United States Navy Research Unit at the Rockefeller Institute to develop the copper sulphate method for measuring the specific gravities of blood and plasma.<sup>6</sup> A drop of blood in a copper sulphate solution becomes encased in copper proteinate—and so remains discrete, and sinks or swims according to whether its specific gravity is greater or less than that of the solution. If drops of blood are let fall into a series of copper sulphate solutions of known gravity the drops will neither rise nor fall in the solution which has the same gravity as the blood. The specific gravity of plasma or serum is affected only by variations in the protein content, and the total plasma or serum proteins can be estimated as accurately by the copper sulphate specific gravity technique as by any other routine method. The gravity of whole blood depends on the plasma protein level and the number and specific gravity of the erythrocytes. If we assume a constant value for the erythrocyte gravity we can calculate, from the whole blood and plasma gravities, the ratio of red-cell volume to plasma volume—the ratio more laboriously but more accurately measured by the haematocrit. If we further assume a normal mean corpuscular haemoglobin concentration then we can calculate the haemoglobin level.

Since it is doubtful whether these calculations offer any substantial advantage over a simple haemoglobin determination in the treatment of shock and burns, the copper sulphate method has established itself principally as an accurate technique for the estimation of the total plasma proteins. There are occasions, however, when use can be made of the fairly close correlation between the whole blood gravity and the haemoglobin level. If we assume normal values for the plasma proteins, the erythrocyte gravity, and the mean corpuscular haemoglobin concentration, then the haemoglobin level can be calculated directly from the whole blood gravity, with an error of about  $\pm 10\%$ . This is too great an error for individual haemoglobin estimations, but if we wish simply to pick out the anaemic members of a large group then the ease and rapidity of the method outweigh its inaccuracy.

The New York Blood Donor Centre used this method to "screen" prospective donors.<sup>7</sup> A drop of blood from the finger was allowed to fall into a copper sulphate solution of gravity 1.052; if the blood sank the donor was accepted; if it floated he or she was assumed to be anaemic, with a haemoglobin level under 12.3 g. Only 4% of donors were wrongly classified by this method. Hynes and Lehmann<sup>8</sup> made a similar application of the method. They showed that the blood gravity and haemoglobin were related more

<sup>7</sup> *J. Lab. Clin. Med.*, 1946, 31, 40.

<sup>8</sup> *J. Physiol.*, 1946, 104, 335.

accurately by an empirical curve than by the original linear calculation; only 3% of 270 men were wrongly classified as above or below a haemoglobin level of 11 g.

In practice, if further investigation of anaemic subjects is intended, it is wise to choose a copper sulphate solution corresponding to a haemoglobin level 1 g. above the chosen limit of anaemia. Then practically no anaemic individuals will be missed, though there will be a corresponding increase in normal subjects classified as anaemic.

## TRAINING CLINICAL PATHOLOGISTS

What are the functions of a clinical pathologist? When this topic was debated in our correspondence columns a year ago attention was chiefly paid to diagnostic laboratory procedures, but, as the Association of Clinical Pathologists points out in a recent report, a function of increasing importance is "the control of treatments of various disorders whose progress can most accurately be assessed by laboratory methods." It emphasizes that a clinical pathologist should have a sound clinical training, including higher qualifications in medicine, as well as a wide experience of laboratory technique. The Hospital Surveys carried out for the Ministry of Health recognized the essential part that this specialty must play in a national hospital service, and there was, as Dyke<sup>1</sup> said commenting on them, "general agreement that satisfactory results cannot be attained by mere isolated examination and report on specimens, but only by direct consultation between practitioner and pathologist."

The Association of Clinical Pathologists appointed a committee in January of this year to consider the training and definition of consultants and specialists in clinical pathology. Its members were E. N. Allott (chairman), S. C. Dyke, R. W. Fairbrother, J. G. Greenfield, and W. H. McMenemey. The committee recommends that the five years after qualification should be devoted to gaining further clinical experience (one year), working in a university department (one year), and working in a department of clinical pathology (two years). In the remaining year the student should extend his experience as he wishes. The object of working in a university department is to train the student in scientific method and to introduce him to an atmosphere where research is being vigorously pursued; the committee suggests that students should be encouraged to take a diploma in bacteriology or in clinical pathology. While working in a department of clinical pathology in a large hospital or a group laboratory the student should receive training in all branches of pathology—a study that should include haematology, bacteriology, chemistry, and morbid anatomy. In this connexion the committee recommends that a special committee be set up to approve those laboratories suitable for this training. Those students who have obtained a first- or second-class science degree—for example, in physiology or chemistry—or a doctorate of philosophy should be eligible for recognition as specialists four instead of five years after registration.

The committee recognizes that these criteria cannot necessarily be applied to existing clinical pathologists or to some of those in training. It advocates, therefore, that at present recognized specialists should have been registered for a minimum of five years and have had at least four years' laboratory experience. They should also hold a higher medical or scientific qualification, or have contributed to the advance of medical or scientific knowledge. In accordance with a decision of the Royal College of Physicians the committee does not think that a register of

specialists in clinical pathology should be compiled. Discussing the financial support that these years of training necessitate and whose lack often debars poorer students from undertaking them, the committee quotes the recommendation of the Royal College of Physicians Committee on Neurology that suitable candidates for the special should be supported by scholarships, Government grant or otherwise.

## CARE OF THE AGED

The Nuffield Foundation is an outstanding example of the modern form of charity whereby help is made available at the point where it is most needed, instead of being frittered away in small sums that keep the wolf from the door only to fail when he jumps through the window. Even our most rigorous planners acknowledge that voluntary aid is desirable, and will remain so, if life is to be not merely sustained but made worth living. The Foundation's latest venture is to sponsor, in association with the Lord Mayor of London's National Air Raid Distress Fund, a National Corporation for the Care of Old People, under the chairmanship of Sir George Wilkinson, Bart., and to provide in the early years with the sum of £500,000. The office will be at 9, Mecklenburgh Square, London, W.C.1. Sir William Goodenough, speaking at the inauguration of the Corporation on July 28, explained that its primary function is to co-ordinate the many agencies that already exist for the benefit of old people. It will not assist individuals but will make grants or loans for schemes for old people welfare, maintain an advisory service, establish and demand desirable standards for organizations applying to it for aid, and undertake research. Moreover, by offering grants or loans, it will take the initiative in areas where welfare for the old is lacking. The Corporation will be a complementary partner of the National Old People's Welfare Committee.

As the Rowntree Report<sup>1</sup> pointed out, the old more often suffer from loneliness than from dire poverty. The Nuffield Foundation has taken account of this in its 1947 Report and emphasizes that the community must not become stratified into large groups: provision for the old, in the interests of both old and young, must "be so planned that it is integrated into the life of younger sections of the community so as not only to enliven the surroundings of the older generations but also to enable the young to contribute in awareness and in activity to the welfare of the old. It would nevertheless be regrettable if widespread public arrangements for their welfare should diminish the sense of family responsibility to look after elderly relatives. The Report recognizes that many more suitable dwellings should be built for the old rather than experiments carried out on types of housing, of which enough have already been done. Discussing the dwellings themselves, the B.M.A. Committee on the Care and Treatment of the Elderly and Infirm<sup>2</sup> stressed that houses for the elderly should be decorative, situated where the residents have previously lived so that they may keep in touch with the friends, near churches and shops and places of entertainment—not "machines for living in," to use a phrase popularized by Le Corbusier, but homes. The Ministry of Health, too, has impressed on local authorities this aspect of housing the old. Voluntary aid is perhaps essential to provide this distinction, and the Corporation is well fitted to the task.

## SURGERY IN TWO WARS\*

BY

Major-General PHILIP H. MITCHNER, C.B., C.B.E.  
M.D., M.S., D.Ch., F.R.C.S., D.L.*Hon. Surgeon to H.M. the King; Surgeon to St. Thomas's Hospital*

Before comparing the surgical procedures, or the success which attended them, in the two wars of 1914-18 and 1939-45 it is necessary to consider the social conditions under which the troops existed and the differences in the types of warfare during the two periods. In 1914-18 the men lived in underground shelters, ill-ventilated, ill-heated, and, during the winter, frequently with cold and stinking mud up to the knees or above. The hygiene necessitated by this static war, and the hasty and inadequate burial of the dead, often in the walls of the dugouts themselves, led to insanitary conditions, horrible odours, and infestation with rats and vermin, which rendered life disgusting and almost untenable. Can it be wondered at that after being wounded men had no desire to return to these conditions? Little attention was paid to proper cooking and serving of rations. As a result the men's physical condition and resistance to infection was very poor.

In the 1939 war, once the period of waiting in France was ended by the German break-through, troops were continually on the move. This necessitated physical fitness and mental alertness and provided changes of scene and locality, which permitted of adequate hygiene. The thorough graduated training which the troops underwent at home before proceeding overseas acclimatized them to active service conditions. Such men were desirous and capable of an early return to the fighting front. Moreover, from the early days of the war attention was paid to the type of ration issued and its cooking.

## Mobile Surgical Teams

It was difficult to deal promptly with surgical procedures in this very mobile warfare and the medical services took some time to devise a scheme whereby surgery would be available to the wounded within a few hours of injury. This was ultimately met by the formation of mobile surgical teams.

At first the over-enthusiastic, both medical and combatant, pushed isolated teams too far forward, forgetting that a mobile battle swayed to and fro over ten or fifteen miles, and that a solitary team was incapable of carrying on indefinitely and unable in the front line to retain its casualties after operation for that ten-day period so essential for full recovery. Later, therefore, mobile surgical teams were held at some distance from the battle area in groups of two or three to provide continuous service throughout the twenty-four hours. To ensure retention of patients for ten days and their adequate nursing (so much more efficient in the hands of women than of men) these teams were usually located at an advanced surgical centre with a casualty clearing station. Here such valuable adjuncts as female nursing, x rays, and blood transfusion were available.

As a general rule it may be said that specialists should not be advanced further forward than the C.C.S. with its advanced surgical centre, and that in the main they are better held at the base hospitals, casualties being dealt with in the field by general surgeons on certain well-defined principles agreed with the specialists. Possible exceptions to this rule are orthopaedic and thoracic units, which can under certain conditions be situated advantageously at the advanced surgical centres in the C.C.S. Here too is the best position for the blood transfusion, pathological, and x-ray units.

\* Abridgement of a lecture delivered before the Royal Faculty of Physicians and Surgeons, Glasgow, on Jan. 29, 1947.

## Blood Transfusion

One of the great advances of this war is the institution of blood transfusion—given forward and almost as a routine, though in the mud and blood of the average regimental aid post in battle it is dangerous and has been known to produce fatal septicaemia. As a general rule all blood lost should be replaced quantity for quantity and an extra pint (568 ml.) or even two pints administered subsequently; but in cases of shock where no haemorrhage has occurred blood must be given slowly and cautiously, not more than forty drops to the minute in rate. Seldom more than two pints (1.1 litre) in total quantity is necessary before the patient's pulse becomes perceptible within the limits of normality, indicating that transfusion should be stopped. Should this period be missed, a rising pulse rate and rapidly increasing respirations may lead to the erroneous administration of blood and plasma—often fatal in its results. The patient dies of pulmonary oedema or uraemia following blockage of the renal vessels with disintegrating and unexcreted red cells.

## Chemotherapy

When the war started we had the sulphonamides, and full use was made of them. As a general rule it may be stated that their administration orally in doses of 1 g. 4-hourly for the first 24 or 48 hours and subsequently 0.5 g. 4-hourly until the infection is controlled, as shown by a fall in temperature and pulse, is far more beneficial than their local application to the infected wound. In staphylococcal infections they have little or no effect, and if their administration is not followed by a fall in temperature and pulse rate by the end of 48 hours they should be discontinued, for they are intensely toxic, especially to certain individuals.

About 1943 we were fortunate in obtaining penicillin. Applied locally, and provided it could reach all parts of the infected surface, it was adequate in clearing up local infection, and if applied to the recent wound was a satisfactory prophylactic if early and adequate surgery were combined with its use. Given systemically it proved of great value in combating general and local infection, and its results were almost miraculous against gas gangrene.

## Surgery

The principles of war surgery remained essentially the same in both wars, though the lessons of the former had been largely forgotten in the interval. The damaging power of the missiles used in this war was much greater than those in 1914-18, though their concentration was much less. Severe lacerated wounds with considerable disruption of the surrounding tissues were commoner and more severe in the recent war.

The principle of operation within 6-10 hours, excision of a thin margin of skin and all damaged and infected muscle tissue until red contractile muscle with spurting vessels was encountered, held equally good in each war whether chemotherapy was applied or not. Chemotherapy is but an adjunct to early and efficient excision of every wound.

Primary suture and delayed primary suture—i.e., suture within the first three days after wound toilet—have been carried out on a large number of cases in all theatres of war (1939-45), and combined with routine chemotherapy, especially systemic penicillin, have resulted in successful healing in 80% of the cases in flesh wounds and 73% in lacerated wounds associated with fractures. Secondary suture, carried out under similar conditions, has had success in approximately 75% of cases in both classes of wound. These results are greatly in advance of those achieved by similar procedures in the 1914-18 war or the early stages of this war when chemotherapy was not available.

The mortality from multiple wounds, which occurred more often in this war than in the last, is considerably higher than in wounds involving one viscus alone (58.3% against 39.7%). Chemotherapy will in some cases permit a perforating wound of the abdomen or chest or head to be dealt with and a limb wound to be left for toilet until the following day, when the patient's condition has improved, but in many cases this is not possible because the multiple wounds involve head, thorax, and abdomen and all need urgent treatment.

Burns have been more common and more extensive in the recent war. It is difficult to obtain any figures of the mortality resulting from extensive superficial burns, since many died before reaching medical aid or, after first-aid treatment, before getting back to base hospital. Burns units subsidiary to the plastic units were of great value in the treatment of those burns which reached them, for an experienced team treats this sort of injury better than casual nursing can do.

### Abdominal Wounds

In perforating wounds of the abdomen it is seldom that one viscus alone is damaged. Usually there are multiple wounds of the small intestine, often wounds of the larger intestine and the bladder, and perforation and disruption of one or more solid viscera, while abdomino-thoracic wounds are not uncommon, constituting about 12% of the total wounds involving the abdomen and thorax. In the 1914-18 war a perforating abdominal wound carried an overall mortality of 70-75%, and approximately 50% of those operated on recovered; in the 1939-45 war a similar wound carried an overall mortality of 50%, with a recovery rate of 30-35%. This better prognosis was partly due to the possibility of earlier surgery—owing largely, I think, to the lesser number of wounds occurring in battle to the proportion of surgeons employed in their treatment.

Suture of perforations is performed preferably unless the small bowel or its mesentery is greatly disrupted, when excision and anastomosis are carried out. In the case of large-intestine wounds, however, the 1939-45 war in its latter part saw a great advance in the routine exteriorization of the colon and the performance of colostomy in wounds of the rectum. This led to a considerable diminution in the mortality from these wounds. In the light of further experience it appears that exteriorization of the caecum and ascending colon is not only unnecessary but makes an additional risk for the patient as against those cases where such wounds are treated, like those of the small intestine, by primary suture. Furthermore the closure of the colostomy or restoration of the exteriorized bowel to the abdominal cavity is not entirely free either of immediate or of remote mortality.

Chemotherapy has improved the prognosis; but the introduction of sulphonamide powders into the peritoneum is fraught with the considerable danger of subsequent adhesions and intestinal obstruction and is not a practice to be indulged in with impunity.

The treatment of bladder wounds is by primary suture or, where other viscera are involved, by suprapubic cystostomy. The kidney is not infrequently damaged and usually needs excision. Splenectomy is generally required for wounds of the spleen. If severe, wounds of the liver cause a rapid death, and if slight seldom call for drastic surgical intervention. At all costs plugging, with a risk of subsequent infection, must be avoided. Abdomino-thoracic wounds constitute about 12% of wounds of the abdomen. As a general rule it is better to deal first with the thoracic lesion, suturing the wound of the lung and of the diaphragm, and then to tackle the abdominal damage.

### Thoracic Wounds

It has been the practice in both wars to treat an uncomplicated haemothorax by aspiration alone. The complication of infection, frequently with fatal results, has occurred in both wars. Whereas in the 1914-18 war infection occurred in some 54% of cases of haemothorax treated conservatively, in the early part of the 1939-45 war infection occurred in 33%, with a death rate of 6%. With chemotherapy the infection rate has dropped to 6%, with a death rate of only 1%. Of all thoracic wounds approximately 10% were complicated by abdominal injuries. The death rate in these cases was considerably higher than in those of uncomplicated thoracic wounds (approx. 50%). In all wounds causing an open haemothorax early closure of the gap is essential; in the front line this can be achieved quite efficiently by a large dressing tightly applied. Such cases should not be treated by operation in front of the advanced surgical centre.

### Comparison of Mortality

It is difficult to make an accurate comparison of mortality from wounds in the two wars, but the results of the average

percentage mortality of the various wounds of abdomen thorax are epitomized in the following table.

Percentage Mortality of Wounds in the Two Wars

1914-18	Organ	1939-45
51%	Perforating wounds of abdomen	39.7-47%
50-55%	Small intestine	32-40% { Suture 20% Resection 58%
50-73%	Large intestine (colon)	36-40%
49%	Rectum	25-70%
61%	Stomach	29-38%
30%	Bladder	5-20%
29%	Liver	18%
26-6%	Kidney	5-45%
53%	Spleen	13%
65-85%	Abdomino-thoracic	27-60%
54%	Thoracic	5.7%

### Fractures

In severe lacerating wounds involving bones the primary of the surgeon is the treatment of the wound with meticulous excision of all damaged muscle tissue. The reposition of bone fragments in good anatomical position is of second consideration to this, which prevents the danger of gas gangrene and other infections. Routine administration of anti-gangrene serum, chemotherapy, and fixation of the wound plaster-of-Paris in extension are essential. Over-distraction of the fragments, a practice to which there has been an inclination in this war, just as much as the increased violence of disruption accounts for the marked delay in union seen so often. W main vessels are injured and nerves divided, and more especially if joints are laid open and muscle grossly crushed, it is a saving operation to perform immediate amputation, and, tourniquet has been applied, without its previous removal of the damaged limb.

### Wounds of Nervous Tissue

The results obtained in treating injuries to peripheral nerves are much the same as those in the 1914-18 war. Primary suture without tension or torsion gives the best results, and this is more often possible with adequate chemotherapy. Nerve grafting and other operations to try to restore gaps are of value, and where a gap cannot be bridged by mobilization of the nerve it is better, if possible, to remove a section of the nerve in order to shorten the limb and permit suture. Secondary suture gives less satisfactory results than primary suture, is still the practice of many surgeons. Where this is carried out it is essential to remove the neuroma which has formed at the ends of the divided nerve before suture is performed. The period of recovery is long—for instance, up to five years for high sciatic lesion and two to three years for lesions of nerves in the axilla or upper arm.

Head injuries should be dealt with by a surgeon special in brain surgery, and it is better to transfer such cases after a routine toilet of the superficial wound. Wounds of spinal cord are always disappointing in their results, but surgery to relieve pressure on the spinal cord often brings an unexpected recovery of function. In all cases where paraparesis and retention of urine are present the routine and early performance of suprapubic cystostomy has been proved essential.

### Gas Gangrene and Tetanus

The prophylactic use of anti-gas-gangrene serum and chemotherapy has done much to diminish the incidence and extent of gas gangrene, but without adequate and early surgical removal of all damaged muscle tissue as a routine in the treatment of wounds these aids to the prevention of gas gangrene are useless and dangerous. Tetanus has been relatively seldom seen in the recent war, which may be due partly to the more modern warfare and absence of gross fouling of the soil; but one must think that the routine injection of tetanus toxoid has much to do with the diminution of this scourge.

In this attempt to contrast the surgery of the two wars, difficult and, as I shall doubtless find, contentious attention I am indebted to many colleagues for their assistance in obtaining the figures, and especially to Brigadiers Buxton, H. Edw and Fettes.

## FRENCH RAILWAY (NORTHERN REGION) X-RAY TRAIN

BY

PIERRE LE GÔ, M.D.

*Chief Medical Officer of the Northern Region of the French National Railway Company*

In 1932 two railway coaches, one fitted with radioscopic and diographic apparatus and the other as living quarters, were put into service on the Northern Region of the French Railways for use in the prevention of disease among members of the staff and their families. Railway rolling stock was chosen for this purpose, as offering reasonable comfort at a minimum operational cost.

In 1933 a "waiting-room" coach was added, and the three coaches were in constant use until the exodus of 1940. After short interval the service was resumed in September, 1940, and continued until April 21, 1944, when the train was badly damaged during an Allied air raid on the sidings of La Chapelle, in Paris. Until new coaches could be provided the medical examination of staff and families, which in these circumstances then obtaining had become more essential than ever, was carried on by means of a portable radioscopic unit lent by the French Health Ministry and conveyed by road. A new train has recently been completed at the French railway workshops of Le Landy, just outside Paris. It is made up of two sections: (1) a radiological coach, a coach fitted up

FIG. 1.—The waiting-room.

living-quarters, and a coach fitted up as a waiting-room; and (2) a radiological coach which can function independently. The radiological coach included in the first section comprises a small waiting-room with accommodation for twelve persons, two dressing cubicles which communicate on one side with the waiting-room and on the other with the doctor's consulting-room (equipped with a couch for examination purposes), a radiological room fitted with radioscopic and radiographic apparatus, a laboratory for developing x-ray photographs, and finally an attendant's compartment with a collapsible bunk. The living coach provides quarters for the doctors and nurses, and includes a kitchen, a dining compartment accommodating 6 persons, 2 bedrooms for the doctors and 2 for the nurses, and 3 dressing-rooms with lavatory. The waiting-room coach has seating accommodation for 54. The interior fittings are very simple, and include hinged benches with collapsible backs which can be turned up against the sides of the coach to facilitate cleaning, two lavatories, and an alcove containing boiler for central heating. It may be mentioned that special fluorescent lighting has been fitted into this coach.

The Medical Service plans to use this coach also for meetings, to give lectures on welfare, etc., to the families of the staff, and to serve teas to the children. For this purpose alternate benches can be replaced by tables.

### Equipment of the Train

*Section 1.*—The system of heating is the same for each coach, with a self-contained unit feeding the radiators, the

FIG. 2.—The dressing cubicles.

size and number of which have been fixed to give the requisite temperature for each room, according to its use. Current for electric lighting can be obtained in each coach alternatively from a self-contained 24-volt unit or from a 110-volt main supply when the coaches are stationary. Otherwise the equipment follows standard practice, although it may be mentioned that red, blue, and white concealed lighting has also been installed. The radiographic apparatus is supplied with current obtained from a hook-up with the 110-volt main supply circuit. The apparatus, with which examinations can be made in both vertical and horizontal positions, is the one which was in use until 1944, and is of an old but reliable design. It has, however, been improved upon, and appropriate precautions have been taken to protect the doctor and assistants against the danger of high-tension current. Special precautions have also been taken in order to avoid the risk of damage to the radiological apparatus while the train is in motion.

*Section 2.*—This section consists of one coach, which can function independently or simultaneously with the first. It is equipped so that examinations can be effected with considerable rapidity. It comprises a waiting-room (Fig. 1), 14 dressing cubicles arranged in two groups of seven on each side of a central corridor (Fig. 2), a consulting-room for the doctor (Fig. 3) equipped with a desk and a couch for more thorough examinations, and a radioscopic room from which the nurse can communicate with the doctor by telephone. In this way the doctor can transmit his diagnosis to the nurse, who can in turn give to the doctor the case-history of the patient from the health-card.

The medical staff are protected against the action of rays by a leaden screen fitted between the apparatus and the nurses' office (Fig. 4). The radioscopic apparatus, which is very up-to-date, has been designed for systematic mass examination, and includes: (1) A vertical radioscope, fitted with a leaden partition screen to protect the operator against direct radiation. This machine is of particular interest inasmuch as the patient can be examined in the light and can move about freely, the

FIG. 3.—Doctor's consulting-room, showing x-ray screen.

operator alone being in darkness. This is a very desirable feature, as it considerably reduces the time taken for each examination. (2) An x-ray generator specially adapted for this type of examination and giving a very clear and detailed picture. It is designed for use off the main supply or from the rotary convertor. Its capacity is such that examinations can be carried on for hours at a stretch. (3) Finally, there is a switch-gear control for the generator. The whole of the electrical equipment can be worked off the main supply or a generator.

#### Its Value in Preventive Work

By means of this radiological train it is possible to carry out examinations of both the railway staff and their families, particularly with a view to the prevention of tuberculosis. By travelling from station to station the benefit of these examinations is extended to employees living in small localities where there is no qualified lung specialist. In this way it completes the work being done continuously in the eight tuberculosis centres of the Northern Region of the French Railways by means of existing installations. As 600 people a day can be dealt with in this train it will be possible to examine every member of the staff of the Northern Region of the French Railways and their families at least once a year.

Useful and profitable as this work is, the Medical Service has decided that the prevention of tuberculosis should not be its sole object. It is intended to carry out on each subject a thorough and complete annual examination covering the whole

FIG. 4.—Nurses' office, showing examinees' side of x-ray screen.

body. To this end it is planning the addition of a further coach to the radiological train, completely equipped for a rapid examination of the different organs of the body. Thanks to the facilities offered by this new coach, the person examined will undergo measuring, weighing, blood-pressure test, analysis of urine, examination of the heart, and reflexes of the eyes and ears, as well as a blood test and cardio-pulmonary radioscopy. The results of these examinations will be recorded on case-history cards, which can be mechanically sorted and classified.

#### COLONIAL MEDICAL RESEARCH STUDENTSHIPS

In the *Journal* of June 21 (p. 897) we announced the institution by the Secretary of State for the Colonies of ten research studentships for graduates in medicine and cognate sciences. We have received an amendment from the Colonial Office to the second sentence of the announcement, which stated the allowance to be made to holders of the studentships, as follows: A graduate awarded a studentship will be eligible for a maintenance allowance assessed according to personal circumstances. The maximum rates of allowance which may be paid are: £260 per annum at the Universities of Oxford and Cambridge; £250 per annum at the University of London; and £220 per annum at other universities in the United Kingdom. The allowance will be free of income tax. A studentship will normally be awarded for a period of two years, subject to satisfactory report at the end of the first year's work from the supervisor, who will be nominated by the Colonial Medical Research Committee.

#### WORLD FEDERATION OF PATHOLOGISTS

The European Association of Clinical Pathologists, under the Presidency of Dr. S. C. Dyke, met at Cambridge on June 27 and reconstituted itself as a World Federation of Societies devoted to Clinical Pathology. The Federation defines its aims as (1) to develop clinical pathology—the application of pathology and allied sciences to medicine; (2) to have regard to the scientific and professional status of those engaged in its study and practice; and (3) to foster international amity. A committee was appointed to call a meeting of delegates from as many interested associations as possible in Paris next November, during the meeting of the French Société de Biologie Clinique, in order to formulate a constitution and elect officers. Dr. Dyke was appointed chairman of the committee, Drs. W. H. McMenemey and J. Ungar joint secretaries, and Dr. R. Cruickshank (London), Prof. Raoul Kourilski (Paris), and Dr. F. Piek (Prague) advisory members.

The Federation hopes to gain a world-wide membership, and invites societies devoted to clinical pathology to communicate with the secretaries—either Dr. W. H. McMenemey, the Pathological Department, The Royal Infirmary, Worcester, or Dr. J. Ungar, Glaxo Laboratories, Greenford, Middlesex. The Czechoslovak Association of Clinical Pathologists, the French Société de Biologie Clinique, and the Association of Clinical Pathologists of Great Britain have already signified that they wish to join the Federation. Medical practitioners or university graduates practising clinical pathology who are members of the constituent bodies will thereby become members of the Federation. Membership is also available to those who are eligible but do not belong to a constituent body. The Federation proposes to hold a conference at least once in every three years at the same time and place as the summer meeting of one of its constituent bodies. It hopes that the first will be in the summer of 1948.

#### THE MEDICAL PROTECTION SOCIETY

The London and Counties Medical Protection Society, at an extraordinary general meeting on July 16, agreed to simplify its title by omitting the prefix "London and Counties." Sir Ernest Rock Carling, who took the chair at the annual meeting which followed, said that the Society had had a very successful year. New members joining in 1946 numbered 1,894, bringing the total membership to over 22,000. The work of the Society had also increased. Applications for advice and assistance were received during the year in 1,410 cases. The Society had had to meet heavy legal expenses, and it had been again brought home to it that even the most expert and careful doctor sustained misfortunes or committed errors which might result in heavy damages. Moreover, the general costs of litigation tended to increase.

The Society was constantly hampered in its work by the failure of practitioners to keep records. He commented on what seemed to be the tendency of judges to attribute the blame for the effects of a disease or injury to the unfortunate doctor who had had the case in his care—not merely the portion of blame which might be put at his door owing to some lack of skill or error in treatment but the blame for the entire disability—and this was often reflected in the costs. Perhaps the most important activity of the year was the part taken by the representatives of the Society in making representations to the Ministry of Health concerning the Bill now being promoted by the General Medical Council for the reform of its constitution and procedure.

The treasurer, Mr. W. M. Mollison, submitted the accounts, which were in a thoroughly healthy condition, the investment amounting at cost to over £100,000. Sir Ernest Rock Carling was re-elected president, and to fill vacancies among the vice-presidents caused by certain retirements Dr. Thomas Beaton, Mr. F. A. Juler, and Dr. G. M. Stoker were elected. The new members elected to the Council were Dr. Annis Gillie and Dr. F. H. Stevenson.

The offices of the *American Journal of Ophthalmology* have been moved from Cincinnati to 700, North Michigan Avenue, Chicago, 11, Illinois.

## PURE AND APPLIED CHEMISTRY

## ELEVENTH INTERNATIONAL CONGRESS

The proceedings of the Eleventh International Congress of Pure and Applied Chemistry, held in London from July 17 to 24, covered a wide variety of topics of medical interest. Joint meetings between sections primarily concerned with human beings, animals, and plants proved of special value. Sir Henry Dale's congress lecture on "The Part of Chemistry in the New Therapeutics" was published in our last issue (Aug. 2, p. 161). The report which follows excludes also discussions on bacterial chemotherapy, the principal points from which were summarized last week in a leading article (p. 179), and the reported discovery of a lactation vitamin which was the subject of an annotation (p. 181).

## Intermediary Metabolism

A discussion on intermediary metabolism held by the Section of Biochemistry provided further evidence of the large part which radio-isotopes may be expected to play in future investigations of this type. Prof. G. von Hevesy's laboratory in Copenhagen was the first to introduce this method for the purpose of directly measuring the replacement rate of phosphorus in the teeth of the rat. He has now used the same radio-element ( $P^{32}$ ) to study the phosphorus metabolism of the blood, while with radio-nitrogen ( $N^{15}$ ) he has determined the average lifetime of human red corpuscles as about 4 months and that in the case of the hen as 30 days. This work appeared as an interesting supplement to that carried out in the United States with the two radio-irons on blood storage and transfusion, and Prof. Hevesy presented a reasoned analysis of the research uses of these four radio-isotopes. Radio-iron, he pointed out, necessarily involved the metabolic complication of a donor, and it had been shown also that the iron released in haemolysis was largely used in the formation of new cells. With radio-phosphorus, on the other hand, corpuscles could be "labelled" *in vitro* and re-injected into the original subject. In this way it had been shown that there was a high interchange rate both of inorganic phosphorus as between serum and red cells, and of inorganic and organic phosphorus within the cells. For the purpose of cell life measurements in the case of the hen, use has been made of the fact that the desoxyribose nucleic acid of the red cells remains unchanged during the lifetime of the cells. It has been shown that all red cells in the hen have about the same lifetime. The corresponding human measurement, yielding the 4 months' lifetime already quoted, was based on the administration of glycine labelled with radio-phosphorus.

Dr. G. E. Francis and Dr. A. Wormald, of St. Bartholomew's Hospital Medical College, have already published a series of investigations on the interaction of mustard gas and proteins as shown by radio-sulphur ( $S^{35}$ ). They have now extended the same method to immunological reactions. By injecting hens with radio-phosphorus, they obtained from their eggs a naturally produced but radio-actively labelled antigen, radio-vitellin. They were thus able to determine the amount of antigen in various vitellin-anti-vitellin preparations. Other investigations have been made with artificially phosphorylated proteins labelled with  $P^{32}$ , and with an antigen containing radio-sulphur. The latter radio-isotope has also been used by Dr. L. Young and Dr. S. D. Simpson, of Toronto, to show the distribution within the organism of sulphur from British anti-lewisite (BAL).

Prof. V. du Vigneaud, Cornell University Medical College, who earlier in the Congress had described the first isolation of pure synthetic penicillin, has used labelling of a different type. Largely as a by-product of wartime work on the separation, on the basis of mass, of the two principal isotopes of uranium, various normal and stable elements are now available in which partial separation of isotopes of different masses has been effected. Their use in research is dependent on accurate density measurements. With sulphur enriched in  $S^{34}$  (normal atomic weight 32.07) and carbon enriched in  $C^{13}$  (normal atomic weight 12.00), Prof. du Vigneaud studied hair formation in young de-haired rats. Methionine was synthesized in which the sulphur and two known carbon atoms were thus labelled. He found that 80% of the sulphur in the cystine of the rats' new

coat was derived from dietary methionine, but that no significant proportion of the carbon came from the labelled atoms of this element. This suggested the formation of cysthionine as an intermediate.

## Blood Factors and Immunology

Dr. W. T. J. Morgan, of the Lister Institute, during a discussion held by the Medical Section on "Macromolecules of Biological Interest," described a technique which he has developed for the separation of the human specific blood factors (A, B, and O) from ovarian cyst fluid. In fluid from ovarian cysts the group substance was often present in considerable amounts and in water-soluble form. It was a mucoid and could usually be isolated by treating the diluted cyst fluid with trichloroacetic acid at 0° C. The active material, largely free from contaminating protein, remained in solution and could be recovered by dialysis, concentration, and freeze-drying. After extraction with phenol further purification could be undertaken, and the way was thus opened for the further study of these blood-group-specific mucoids.

During the same discussion Prof. M. Stacey, of the University of Birmingham, referred to the bridge which is being established between immunology on the one hand and chemical research on the large and complex polysaccharides produced by bacteria on the other. The most important work of recent years, he stated, was that of Heidelberger and his associates who, by injection with specific pneumococcal polysaccharides, had successfully immunized human patients against several of the common types of pneumococcal infection (e.g., Types I, II, III, V, VII, and VIII). U.S. Army field trials had shown the great potential value of the method; and Avery, by laboratory methods, had transformed one type of pneumococcal polysaccharide into another. In the *Salmonella* group also it had been shown that such complex polysaccharides were the essential immunizing antigens of the cell. On the more strictly chemical side a number of bacterial polysaccharides had been built up from sucrose and glucose-laevophosphate by enzyme reactions carried out in the laboratory. These studies were elucidating the mechanisms by which these "giant molecules" were formed. Finally, the combination of the normal methods of carbohydrate chemistry and chromatographic methods of separation was bringing to light chemical structures which were new to carbohydrate chemistry. Examples were the specific carbohydrates of *M. tuberculosis*.

## Antigens and Antibodies

Prof. Linus Pauling, of California, approached the problem of biological specificity from the point of view of the physical "fit" believed to be necessary between the antibody and substances with which it interacted. He claimed that by the substitution of single atoms in a complex synthetic chemical used as an antigen it was possible to estimate numerically the closeness of fit necessary. A bromine atom could be replaced by a metal atom of the same size, and antibodies elicited by the bromine-substituted chemical would still be effective against the metal-substituted material. But if a smaller atom such as magnesium was inserted in the same position there would be less complete precipitation because the "hat," represented by the antibody, was now too big for the magnesium-substituted chemical. Also if the smaller atom was inserted into the antigen the antibodies thus elicited showed no reaction whatever with the substituted chemical containing the larger atom—for the "head" was now too big to fit inside the "hat." From such experiments he estimated that the degree of fit needed for full interaction was of the order of 1½ Angström units. For comparison, the difference in atomic spacing between the actual structure of penicillin and that originally suggested is about 1 Angström unit, the wavelengths of visible radiation being measured in thousands of Angström units. Finally, Prof. Pauling suggested that genes might owe their specific power to the same phenomenon of "complementarity."

Prof. J. D. Bernal, Birkbeck College, reviewed progress in protein chemistry. The similarity of the x-ray pattern of all proteins hitherto examined, he stated, indicated a common internal structure down to amino-acid level. Recent work suggested that this was also the case in the giant protein molecules of the plant viruses which Wyckoff had individually photographed by the electron microscope.

### Chemotherapy

Work on the chemotherapy of protozoal infections was discussed by the Medical Section alone and also in joint session with the zoologists. Prof. J. A. Shannon, of New York, who was unable to be present, contributed a summary of wartime research on antimalarials in the United States. An illuminating point which he made was that the continued vigour with which the search for further antimalarials of the atebirin class had been prosecuted had been largely conditioned by the fear, fortunately unfulfilled, that prolonged administration of atebirin might lead to unexpected toxic effects which might have necessitated its withdrawal. Dr. F. H. S. Curd and others of the I.C.I. team which discovered paludrine illustrated from this example the extent to which the search for biologically active substances could be shortened, even in the present state of knowledge, by the imaginative employment of pharmacological and chemical arguments.

In the joint session with the zoologists Dr. L. P. Walls, of the Wellcome Chemical Research Laboratory, described the results of tests in Bechuanaland and the Gold Coast against bovine trypanosomiasis with dimidium bromide ("1533") and phenidium chloride ("897"). Both are members of a group of substances which were first prepared as antibacterials by Prof. C. H. Browning, of Glasgow. A protracted prophylactic action has been obtained, but care is necessary in treatment to avoid toxic reactions. Mr. H. J. Barber, of the research staff of May and Baker, reviewed amidine chemotherapy, which he pointed out had been somewhat overshadowed by penicillin and the antimalarials. Its field of usefulness was, however, being gradually extended, and current work was establishing the value of 4:4'-diamidinodiphenoxypentane in the prophylaxis of human (African) sleeping sickness.

Dr. W. Bradley, British Drug Houses, discussed the effects of various types of substitution on the muscle-relaxing drugs of the glycerol series, research on which had been stimulated by recent applications in medicine and surgery. In the aryl ester series, maximum activity was reached with the introduction of simple groups, more complex substitution again reducing the activity. The nature of the substituted group, whether alkyl, alkoxyl, or halogen, was less important, although both basic and acidic groups abolished the activity. The results as a whole suggested that both the size and the shape of the molecule affected the muscle-relaxing property.

### Nutrition

Discussions on nutrition ranged widely. One on the effects of dietary restriction in man, introduced by Sir Jack Drummond, brought together information from the Far East, France, and Brussels, as well as the results of the Minnesota experiment in rehabilitation. Other contributions described the effect of wartime shortages on livestock.

Dr. D. A. Smith, of the London School of Hygiene Nutrition Unit, quoted the records of the Hong Kong civilian internment camp to show that, even with a severe deficiency of calories, there was a tendency to establish equilibrium at a lower metabolic level. After a year on 1,850 calories a day, weight loss had ceased at about 25% below normal. Numerous subjective phenomena were experienced, and psychological changes were attributed rather to general under-nourishment than to specific vitamin deficiencies. Results during the starvation period of the Minnesota experiment, described by Prof. A. Keys, Director of the University Laboratory of Physiological Hygiene, were in close agreement with the Hong Kong figures, except that balance at the lower level was attained more quickly; 32 young adult males, who had required 3,000 calories for balance during three months of normal feeding, were balanced at about 1,700 calories, at 76% of normal weight, after six months. Three months of restricted refeeding followed, and finally 10 months of unlimited diet. Changes in body water and fat obscured "active tissue" recovery, if evaluated from gross weight alone. In general, functional recovery paralleled the recovery of active tissue, and under the most favourable conditions full rehabilitation required from 6 to 12 months. Supplementary vitamins and proteins were found to be not important. At intakes of less than 3,000 calories recovery was "very slow," and above 4,000

the added weight was mostly fat. Dr. J. Trémolières, of the National Institute of Hygiene, Paris, compared the average deficits in height and weight shown by boys and girls during the period 1944-5 in a number of French cities. Deficits in height were most noticeable in boys, and in weight in girls. They appeared after the age of 9, and increased quickly to maximum at 14. They were reduced by about 50% between November, 1944, and November, 1945, as the food situation became better. The Belgian experiment was of short duration. It showed that ten days of special feeding was enough to bring about a marked increase in strength of grip in a group of factory workers.

Reports on livestock in wartime came from Sweden and Great Britain. Dr. S. Nordfeldt, of the Royal Agricultural College, Uppsala, stated that the use of a special wood pulp fodder, which between 2 and 3 kg. could be given daily to cows, had enabled milk deliveries to be maintained without restriction all times. Dr. S. J. Rowland, of the National Institute for Research in Dairying, Reading, attributed an acute late-winter decrease in solids other than fat from 1941 onwards, and persisting to the present time in the milk from British cattle, to reduced supplies of imported concentrates. This was, however, superimposed on a steady decline in the quality of British milk over the last fifteen to twenty years, both in fat and "solids-in-fat." He thought this was due to excessive concentration of breeding for yield, without reference to composition or to balance in which different breeds were represented. The quality of Norwegian milk was stated by Dr. G. Aas, of Oslo, to have improved from 1927 to 1940, and then declined to about former level. Dr. James Stewart, of the Morcudun Institute, Edinburgh, made the point that the known effects of local trace element deficiencies on livestock provided a strong argument against "non-scientific opinion" which sought to prevent use of artificial fertilizers on health grounds. Other examples came from plant nutrition.

Prof. A. N. Worden, of Aberystwyth, threw out the further suggestion to the medical profession that the results of studies on lambs and calves, showing the significance of colostrum relation to antibody production and nutritional status, suggested that "it would be well worth while to re-investigate by modern methods the role of breast milk, including colostrum, in disease resistance in the human child."

In a discussion held by the organic chemists on vitamins, I. D. A. van Dorp, of N.V. Organon, Oss, Holland, argued for a comparison of chemical structure and physiological action of different vitamin A derivatives that the functions of visual control, growth, and oxygen transport should be regarded separately. Dr. L. J. Harris, of the Dunn Nutritional Laboratory, Cambridge, gave a critical survey of methods of vitamin estimation.

### MEDICAL ARTISTS

The exhibition of oil paintings and water colours arranged by the Medical Art Society at the house of the Royal Society of Medicine suggests that members of the medical profession will find their recreation in painting like to get as far away as possible from the professional scene in their choice of subject. Of the 150 frames only one encloses a medical subject—an operation performed in a hospital ship, the work of former Surgeon Lieut.-Commander E. Puddy. Nearly all the rest are landscapes or still life. Portraiture is almost absent, though an exception is "House Physician," a splendid example of an African doctor, by Elliott Blake, who also shows a lunatic "Dunkirk." But the quiet English countryside is the recurring theme. Even Sir Philip Manson-Bahr takes us no further than the Tropics than the woods and fields of Surrey. Harold Gillies finds his inspiration in Norway and Iceland. Dr. John Parkinson favours the Channel harbours. Mr. Norman Patterson concentrates on flowers and glassware. Dr. T. Somervell, the climber of Everest, turns to mountain scenery. Here and there is an example of the grotesque, such as the explosion of the atom bomb in the garden of Eden, but most pleasant straightforward transcriptions which must have given their producers keen pleasure, and some of that pleasure they transmit to others.

# LIVOGEN

Trade Mark

Dietary deficiencies of vitamins of the B. group are frequently manifested by lassitude and debility in patients who, on further examination, may be shown to have a subnormal blood picture. Livogen provides, in addition to fifty per cent. of liquid extract of liver B.P., extract of yeast, Vitamin B<sub>1</sub> and nicotinic acid.

It is of remarkable value in the treatment of anæmias, in the prevention of polyneuritis induced by gastric abnormalities and of the polyneuritis of pregnancy and alcoholism, also in constipation, in anorexia and in retarded growth. Livogen is prescribed also in the various degrees of lassitude and debility characteristic of convalescence, dietary inadequacy and following periods of physical or mental stress.

*Details of dosage and other relevant information are available on request and supplies of Livogen can be obtained from the principal retail pharmacists.*

'AVLON'

brand of

## PETHIDINE HYDROCHLORIDE

Pethidine Hydrochloride possesses analgesic and anti-spasmodic properties, and is used with success in midwifery. It is especially valuable where prolonged labour is due to cervical spasm.

Pethidine Hydrochloride may be employed to alleviate pain in renal, intestinal and biliary colic, in hypertensive headache, and in neuritis of diverse origin. It may be safely administered in therapeutic doses by the oral and parenteral routes with minimal risks of habituation.

Technical literature and further information will be forwarded on request.

### PACKINGS:

Tablets of 0.025 gramme and 0.05 gramme in bottles of 25, 100 and 500.  
Ampoules of 0.05 gramme (1 c.c.) in boxes of 12 and 100, and 0.1 gramme (2 c.c.) in boxes of 10 and 100.

Solution in bottles of 25 c.c. (each c.c. containing 0.05 gramme).

Obtainable from your usual suppliers

## Prevent Discomfort

### IN HAY FEVER AND SUMMER COLDS

To the hay-fever victim the use of 'Benzedrine' Inhaler may make all the difference between weeks of acute misery and weeks of comparative comfort. Its vapour diffuses throughout the entire nasal cavity and is strikingly effective in reducing the intense congestion which makes allergic rhinitis so distressing.

Head colds are particularly annoying during the summer. 'Benzedrine' Inhaler helps to cut them short and provides welcome symptomatic relief.

Each tube is packed with Amphetamine (B.P.) 325 mgm., Oil of Lavender 97 mgm., Menthol 32 mgm.

### For dual spasmolysis

TRADE **PLACADOL** MARK

### A new antispasmodic for both oral and parenteral administration

Each tablet combines the musculotropic activity of papaverine hydrochloride (60mgm.) with the neurotropic properties of homatropine methyl-bromide (1.5 mgm.). For the relief of all spastic conditions of smooth muscle. Also available in 2 c.c. ampoules.

### And Introducing PLACADOL SED

Each tablet combines the dual spasmolytic activity of PLACADOL with the valuable sedative properties of codeine phosphate (10 mgm.). For the treatment of the more painful spastic conditions of smooth muscle, particularly in post-operative cases accompanied by coughing.

Information on these and other 'WB' products sent on request.

## Towards more

### NORMAL CONTROL

One injection of Globin Insulin (with Zinc) before breakfast controls the blood sugar throughout the twenty-four hours in the majority of mild and moderately severe diabetics. Globin Insulin is a further step towards the ideal — the normal control of blood sugar. 'Wellcome' brand Globin Insulin (with Zinc) — originated and developed at The Wellcome Research Laboratories, Tuckahoe, New York — is supplied in strengths of 40 and 80 units per c.c., each in phials of 5 c.c. Descriptive literature available on request.

## PROGRESS

and the

### B<sub>2</sub> VITAMINS

Views on the singleness of vitamin B have had to undergo considerable revision since the early days of the discovery of vitamins. The original recognition of a single water soluble B vitamin, and further division into vitamins B<sub>1</sub> and B<sub>2</sub>, has been followed by the identification of many other constituents which are now known to form part of the vitamin B<sub>2</sub> complex.

As further progress is still to be expected it is often considered preferable to administer a natural source of the B<sub>2</sub> vitamins, such as Marmite, where all factors appear to be present in balanced proportions—those already isolated as well as those which still remain to be differentiated.

## MARMITE

yeast extract

contains

Riboflavin (vitamin B<sub>2</sub>) 1.5 mg. per oz.  
Nicotin (nicotinic acid) 16.5 mg. per oz.

## NATIONAL (WAR) FORMULARY

The third edition of the *Formulary* will be published shortly. We list below the medicaments that have been added to or deleted from it. In addition a number of minor alterations have been made in the composition of certain mixtures, the naming of drugs, and dosage.

## Additions

## General Section

*Applicatio D.D.T.*—

D.D.T. of commerce	..	..	..	17½ gr.
Emulsifying yxax	..	..	..	17½ gr.
Solvent naphtha (90/160)	..	..	..	145 min.
Oil of citronella	..	..	..	5 min.
Water to	..	..	..	2 fl. oz.

*Auristillac Penicillini*.—An aqueous solution containing 0.05% chlorocresol and, unless otherwise directed, 2,500 units of penicillin (calcium salt) per ml.

*Capsula Pluravit*.—Contains vitamin A, ascorbic acid, and vitamin D.

*Cremor Penicillini B.P.*—Contains, unless otherwise directed, 500 units of penicillin (calcium or sodium salt) per ml.

*Cremor Zinci N.W.F.*—

Zinc oxide	..	..	..	150 gr.
Wool fat	..	..	..	40 gr.
Oleic acid	..	..	..	5 gr.
Arachis oil	..	..	..	150 gr.
Solution of calcium hydroxide	..	..	..	135 gr.

*Cremor Zinci et Ichthammalis N.W.F.*—Zinc cream N.W.F. containing 5% w./w. of ichthammol.

*Elixir Cascarac Sagradae B.P.**Elixir Sennae B.P.C.*

*Emulsio Paraffini Liquidi et Magnesiac*.—Formula as for emulsio paraffini liquidi alkalina B.P.C.

*Gargarisma Phenolis B.P.C.*—Contains 5% glycerin of phenol.

*Gargarisma Potassii Chloratis*.—

Potassium chlorate	..	..	..	80 gr.
Water to	..	..	..	8 fl. oz.

*Guttae Cocinae et Homatropinae*.—An aqueous solution of cocaine hydrochloride 2% and homatropine hydrobromide 1% containing 0.05% of chlorocresol.

*Guttae Penicillini*.—An aqueous solution containing 0.05% chlorocresol and, unless otherwise directed, 2,500 units of penicillin (calcium salt) per ml.

*Guttae Sulphacetamidii Fortes*.—An aqueous solution containing 30% soluble sulphacetamide and 2% boric acid. For use in the presence of infection.

*Guttae Sulphacetamidii Mites*.—An aqueous solution containing 10% soluble sulphacetamide and 2% boric acid. For prophylactic use.

*Injectio Penicillini N.W.F.*—An aqueous solution containing, unless otherwise directed, 50,000 units of penicillin (calcium salt) or penicillin (sodium salt) per ml.

*Injectio Penicillini Oleosa N.W.F.*—A suspension of penicillin (calcium salt) in a 4.5% solution of beeswax in either arachis oil or ethyl oleate, containing, unless otherwise directed, 125,000 units per ml.

*Mistura Gentianae Acida*.—

Dilute hydrochloric acid	..	..	..	10 min.
Concentrated compound infusion of gentian	..	..	..	30 min.
Chloroform water to	..	..	..	1/2 fl. oz.

*Mistura Gentianae Acida cum Nucis Vomicae*.—

Tincture of nux vomica	..	..	..	10 min.
Dilute hydrochloric acid	..	..	..	10 min.
Concentrated compound infusion of gentian	..	..	..	30 min.
Chloroform water to	..	..	..	1/2 fl. oz.

*Mistura Gentianae Alkalina*.—

Sodium bicarbonate	..	..	..	10 gr.
Concentrated compound infusion of gentian	..	..	..	30 min.
Chloroform water to	..	..	..	1/2 fl. oz.

*Mistura Gentianae cum Rhea*.—

Sodium bicarbonate	..	..	..	10 gr.
Concentrated infusion of rhubarb B.P.C.	..	..	..	15 min.
Concentrated compound infusion of gentian	..	..	..	15 min.
Peppermint water to	..	..	..	1/2 fl. oz.

*Naristillae Penicillini*.—An aqueous solution containing 0.05% chlorocresol and, unless otherwise directed, 2,500 units of penicillin (calcium salt) per ml.

*Nebula Adrenalinae et Atrapinae Campasita*.—

Atropine methylnitrate B.P.C.	..	..	..	1/2 gr.
Papaverine hydrochloride B.P.C.	..	..	..	3½ gr.
Adrenaline	..	..	..	2 gr.

Chlorbutol	..	..	..	2 gr.
Dilute hydrochloric acid	..	..	..	5 min.
Sodium metabisulphite	..	..	..	1/2 gr.
Distilled water, recently boiled and cooled to	..	..	..	1 fl. oz.

*Nebula Penicillini*.—An aqueous solution containing 0.05% chlorocresol and, unless otherwise directed, 50,000 units of penicillin (calcium salt) per ml.

*Oculentum Penicillini B.P.*

*Pihula Violae Crystallinae*.—Enteric-coated pills containing 1/6 gr., 1/4 gr., 1/2 gr., or 1 gr. of crystal violet.

*Pulvis Penicillini et Sulphathiazali*.—A sterile powder containing, unless otherwise directed, 5,000 units of penicillin (calcium salt) per g.

*Salvella Penicillini N.W.F.*—Contains either 10,000 units or 12,500 units of penicillin (calcium salt).

*Suppositorium Bismuthi Subgallatis B.P.C.*—Contains 5 gr. of bismuth subgallate.

*Tabella Acidi Acetylsalicylici Campasita B.P.C.**Tabella Butabarbitali (0.1 g.)**Tabella Dienaestralis (0.1, 0.3, 1, and 5 mg.)*

*Tabella Ferri Phosphatis cum Quinina et Strychnina B.P.C.* (equivalent to 30 and 60 min. of syrup).

*Tabella Ferri Sulphatis Campasita*.—Sugar-coated tablets, each containing:

Exsiccated ferrous sulphate	..	..	..	3 gr.
Manganese sulphate	..	..	..	1/25 gr.
Copper sulphate	..	..	..	1/25 gr.

*Tabella Hexaestralis B.P.C. (0.5, 1, and 5 mg.)**Tabella Nicotinamidi B.P. (50 mg.)**Tabella Paludrinae (0.1 g.)**Tabella Phenacetini et Caffeinae B.P.C.**Tabella Phcniodali (0.5 g.)**Tabella Stilboestrolis B.P. (0.5 and 1 mg.)**Tabella Succinylsulphathiazoli (0.5 g.)**Tabella Sulphadiazinae B.P.**Tabella Sulphadimethylpyrimidinae (0.5 g.)**Tabella Sulphaganidinae B.P.**Trachisci Penicillini B.P.*

*Unguentum Calaminae B.P.C. (Unguentum Calaminae N.W.F., 1943, has been renamed Unguentum Calaminae Aquasum B.P.C.)*.—Contains 16.7% of calamine in a base of yellow soft paraffin.

*Unguentum Penicillini B.P.*

## Infants' Section

*Cremor Zinci et Olei Ricini N.W.F.*—

White beeswax	..	..	..	50 gr.
Wool fat	..	..	..	50 gr.
Liquid paraffin	..	..	..	104 gr.
Zinc oxide	..	..	..	36 gr.
Castor oil	..	..	..	240 gr.

*Mistura Gentianae Acida pro**Infantibus**Mistura Gentianae Alkalina**pro Infantibus**Mistura Gentianae cum Rhea**pro Infantibus**Mistura Potassii Bromidi pro Infantibus*.—

Potassium bromide	..	..	..	4 gr.
Syrup	..	..	..	15 min.
Chloroform water to	..	..	..	60 min.

*Pulvis Aluminis et Zinci N.W.F.*—A sterile powder containing potash alum 20%, purified talc 40%, and zinc oxide 40%. Sufficient powder for one application to be packed in stout paper or "cellophane" envelopes, as for pulvis sulphanilamidi.

## Deletions

## General Section

<i>Emuls. Anis. et Menth. Pip.</i>	<i>Mist. Ferri Arsen.</i>
<i>Emuls. Ol. Vitamin. B.P.</i>	<i>Mist. Ferri Perchlor.</i>
<i>Glycer. Proflavin.</i>	<i>Mist. Ferri Salicyl.</i>
<i>Gutt. Cocain. Oleos.</i>	<i>Mist. Hydrarg. Perchlor.</i>

## Correspondence

### Poliomyelitis

SIR,—In your leading article on poliomyelitis (July 26, p. 135) you do not mention swimming and diving in sewage-polluted rivers as a cause of infection. When will the people of this country understand that if they will turn sewage into our rivers and then bathe in them they must expect trouble. Again and again we see cases of infantile paralysis appearing in farms and villages on the banks of polluted rivers. The virus is present in faeces and then passes through sewage into rivers. Young people bathe in sewage-polluted rivers, and we wonder why they get infantile paralysis.—I am, etc.,

New Barnet, Herts.

J. E. ELAM.

SIR,—I would like to draw public attention to the danger of labelling bins "Pig Food." Take off the lid the day before the refuse is collected and you find bones, meat, fat, paper, rotten cabbage mixed up with bits of carpet, sardine tins, newspaper, and a living mass (often several inches deep) of maggots, the last item keeping us well supplied with flies. I suggest that the spread of infantile paralysis may be thus caused, an outbreak of the disease in a hill station in India being coincident with stable manure being thrown on the open ground instead of being conveyed to the destructor.—I am, etc.,

London.

K. O. VAUGHAN.

SIR,—The official memorandum dealing with precautions against acute poliomyelitis (*Journal*, July 26, p. 141) is not very helpful and in places a little ludicrous. For instance, in a disease which is as likely as not air-borne and principally attacks children under five, we read that gargles and nasal sprays have been disappointing.

Would not it have been better to say that the nostrils of the immature should be periodically swabbed out, and that the same can be effectively done by the adult, when washing the face, with the wet fingers, thus avoiding the paraphernalia of a nasal douche, which will certainly not be persisted in more than a few times?—I am, etc.,

London, S.W. 5.

PERCY TATCHELL.

### Oxygen Poisoning in Man

SIR,—May I venture to doubt Sir Leonard Hill's theory (June 21, p. 900) that oxygen convulsions and nitrogen and argon narcosis are both due to carbon dioxide accumulation? Subjectively and objectively the symptoms of the two conditions are utterly different. I have never experienced or observed confusion or euphoria before an oxygen convulsion. Confusion is universal and euphoria common in nitrogen narcosis. Carbon dioxide enhances both oxygen and nitrogen poisoning. The obvious explanation of this fact is that it causes cerebral vasodilatation, and thus facilitates the absorption of other gases by the brain. I hope shortly to publish data which may help to clear this question up.

With regard to the questions of priority raised in his letter, the Official Secrets Act makes a full discussion illegal. No one can doubt the fundamental part played by Sir Robert Davis, but so long as publication is restricted it is impossible to assign credit objectively, and controversy can lead nowhere.—I am, etc.,

University College, London, W.C. 1

J. B. S. HALDANE.

### Tuberculosis in a D.P. Camp in Austria

SIR,—With reference to Dr. F. J. W. Miller's paper on tuberculosis among small children in Newcastle (July 19, p. 91), I wonder if some observations on children in an Unrra-operated D.P. camp in Austria would be of interest. This camp had a shifting mixed Polish and Ukrainian population varying from 1,600 to 2,100. The consequent frequent changes of barracks made tracing of contacts extremely difficult. Indeed, usually no contact with known adult cases could be discovered. No ill child (with the exception of one, whose father's illness

was discovered only through the child) had an infected parent, and none of our infected parents had sick children, but two open cases had positively reacting children with very old calcifications.

I spent one year in this camp. During this time 9 open and 7 closed adult cases were removed to a sanatorium after great moral struggles or left the camp, and 3 closed cases remained in the camp. Shortly after my arrival a number of children over 5 years old were sent to a sanatorium in Italy and did not return, and 5 infected children in a family of 6 remained. These are not included in the following remarks. In this year 10 children under 3 and 3 under 5 years were found to have active primary tuberculosis (I exclude figures for older children), 3 as a result of Evans patch-testing, which was carried out last December in all camps as a preliminary to mass radiography, unfortunately delayed by various difficulties until June.

240 children under 10 were examined, and suspicious cases further examined by the Pirquet test. 46 were positive and were x-rayed immediately and, if not active, again in three months. One child aged 18 months was negative in December but in April was found to have a large infiltration and to react positively. Of the 46, 2 or 3 showed nothing abnormal, 22 showed active or subsiding disease and the rest one or more calcifications. About 12% of adults were x-rayed at some time, and about 50% of these showed calcification of unknown aetiology.

The 13 young children mostly appeared very ill at first, with pallor, sweating, loss of weight, and cough. About half had marked physical signs in the lungs. After a few months all except the baby referred to above, who unfortunately developed whooping-cough, were steadily improving in every way. None of these children had any special treatment other than extra milk and butter, as the mother were very reluctant to allow them to go into hospital and did not enforce rest or early bed or distasteful medicines—or indeed anything the children didn't want. The camp was appallingly crowded, the rooms usually stuffy and either too hot or too cold, but at least was usually managed to give every tuberculous family a room to themselves. Iron and vitamin preparations were taken rather irregularly owing to the mothers' standard of education and difficulty at first in getting iron. Cod-liver oil was not available.

Regular supervision and examination was also very difficult to enforce and indeed only brought about by withholding milk until the mother brought the child, when one would remark to the mother "You evidently consider baby quite healthy, so why should he have extra milk?"

I was surprised at the good results in spite of this laissez-faire attitude. In fact, tuberculosis at all ages was taken rather lightly. The elder patients demanded dog fat to eat and rub on their chests as a sovereign remedy (there was a high mortality among dogs at or time, I believe), and sanatorium treatment was regarded always with great disfavour owing to the separation from family and the discipline required. So long as they got some extra food they didn't see why they should bother or be bothered.

I would be very interested to see pre-war tuberculosis death figures for Poland, as such relatively rapid recovery among children so ill appears unusual to me. Was their degree of illness due entirely to their previous poor nourishment, and the recovery when nutrition was improved a sign of their natural high immunity? All our new cases with the exception of the baby were discovered in the second half of 1946, when food for the whole camp was poor, while from November, 1944 the children's diet was supplemented by International Red Cross parcels.

Similar conditions were found in other camps. Full report will no doubt be published by the Unrra tuberculosis specialists.—I am, etc.,

AGNES C. CLARK.

Northwood, Middlesex.

Late Medical Officer, U.N.R.R.A.

### Meningitis after Spinal Anaesthesia

SIR.—Dr. C. A. Vuylsteke (*B.M.J.*, Feb. 1, p. 179) reported four cases of pseudomonas meningitis following spinal anaesthesia. Three of these, caused by the melanogenic variety of *Ps. pyocyanea* were fatal; one, caused by true *Ps. pyocyanea*, recovered after sulphathiazole treatment. Patients had been operated upon by three different surgeons at two surgical clinics whose nursing personnel belonged to the same school. During this period there had five other cases of meningitis. Careful examination of the cerebrospinal fluid did not reveal the slightest trace of any pathogenic agent. Four patients were cured, one died. Every experienced surgeon will agree that the occurrence of pyocyanic infections in surgical wards means very defective aseptic technique. The author holds the lack of sterilization of the brushes used by the surgeons to scrub their hands responsible

for the meningeal contamination. Since then the brushes have always been sterilized and no further cases of meningitis have been reported.

True infection of the cerebrospinal fluid following spinal anaesthesia may very rarely be attributed to pyohaemia or to ulcerations of the skin; the contamination through anaesthetic solution ampoules also seemed to be very rare, since the phials are not immersed in spirit but dry-stocked and cautiously opened. In my opinion the causes of the cerebrospinal fluid infection in the recorded cases are quite evident. I believe that the sources of contamination are the hands of the surgeons and the instruments.

Prevention means clean hands or gloves and sterilized instruments. Bacteriological sterility of infected syringes and needles can only be secured through two techniques: either warm-air oven (Poupinel) one hour at 150° C. (302° F.), or steam ten minutes at 120° C. (248° F.). Syringes of Record type do not resist these sterilization techniques, and all-glass syringes ("pyrex") are especially useful. We used spinal anaesthesia for 35 years in more than 50,000 cases, and so far no fatal meningitis has been observed in our services. In conclusion, meningitis following spinal anaesthesia can be easily avoided by aseptic measures. Boiling of infected syringes is not sufficient to warrant sterility. Syringes of Record type may be the cause of the C.S.F. contamination.—I am, etc.,

J. SEBRECHTS,  
Professor of Surgery

Bruges.

### Arsenical Dermatitis Treated with BAL

SIR,—I was surprised to read the article by Dr. J. Lawrence Reeve (July 26, p. 132) on the successful treatment of two cases of arsenical dermatitis with BAL. To the best of my knowledge this drug is still on the secret list. More surprising, however, than this premature disclosure is the author's conclusion. After describing the progress of two cases, Dr. Reeve concludes that "BAL may well be the answer to the syphilologist's prayer, for, instead of cases of arsenical dermatitis being in hospital for weeks at a time, they may now be treated as out-patients."

I venture to predict that those venereologists who, through the co-operation of the Medical Research Council, have been able to obtain small supplies of this drug over the past two years or more, and whose experience in its use for cases of arsenical dermatitis extends to many more than two cases, will not subscribe to the author's view as expressed in his conclusion. On the contrary, I feel sure they will continue to regard arsenical dermatitis as a very serious complication to treatment and will, in all but the mildest cases, endeavour to admit their patients to hospital. At the same time they will give thanks to the discoverers of BAL for having provided them at last with a drug whose efficacy cannot be doubted in the treatment of this serious condition and which needs no extravagant or premature claims for its recommendation.—I am, etc.,

Truro, Cornwall.

A. E. TINKLER.

### Primary Treatment of Fingertip Injuries by Skin Grafting

SIR,—I have read with great interest Dr. S. J. Krister's note (July 26, p. 152) on this subject. It is most regrettable that though this method is now part of standard theoretical teaching and is mentioned in most textbooks it is still not used often enough, with consequent daily loss of useful finger-lengths. For the past three years I have routinely used primary plastic procedures in all recent injuries involving loss of skin including well over a hundred fingertips. May I therefore be permitted to make a few comments on Mr. Krister's admirable description?

In industrial accidents—the most common source of finger injuries—clean-edged wounds as are usually caused by slicing machines are relatively uncommon. Crushing with or without avulsion or blunt tearing are the types of trauma most frequently encountered. These make special preparation of a graft bed necessary, but grafting is called for just as much as in the simpler and therefore easier injuries.

Though apparently aware of its importance Mr. Krister has not stressed sufficiently the necessity of excising all devitalized or grossly contaminated tissue. Failure to do so will lead inevitably to sepsis and constitutes the most common source of graft failure. Satisfactory excision of an irregular wound is best carried out in a blood-

less field, and for this purpose I found most efficient a rubber band tourniquet applied near the base of the finger after a ring block. The tourniquet also guarantees absolute haemostasis until the application of the compression dressing, thus avoiding the graft's being lifted up by a small collection of blood or the necessity of applying a ligature beneath the graft—two other causes of failure.

I have found full-thickness grafts quite satisfactory but prefer thick pinch grafts—i.e., those including the full thickness of the dermis in their centre. Using these, perforating the graft is unnecessary, but when the diameter of the defect exceeds 1/2 in. (1.25 cm.) I use two or three grafts applied side by side. With this modification suturing of the graft is usually unnecessary provided a compression dressing is used. As the grafts are harder the percentage of success is nearer 100% than 80%, and the final appearance is equally good.

Except in the presence of a fracture of the remaining bone 14 days is too long a period to keep on the primary dressing. Owing to the necessary thickness of the latter the graft becomes softened and soggy. Change of the dressing is therefore indicated on the eighth or ninth day, even sooner in children. At this time the graft will be found to have already firmly taken and usually requires protective covering for only one further week, thus cutting down the patient's period of incapacity.—I am, etc.,

London, W 1

P. P. H. SCHMIDT.

### Surgical Aspects of Amoebiasis

SIR,—It is unfortunate that Mr. P. Theron's article (July 26, p. 123) on the "Surgical Aspects of Amoebiasis" gives further publicity to the technique of air replacement of liver abscess. This practice, although productive of interesting x-ray pictures, cannot be of benefit to the patient, and the presence of air in the cavity may delay healing. Should repeated aspiration be considered necessary the clinical state of the patient is a reliable guide to its frequency.

If penicillin and sulphadiazine are administered to patients who fail to respond to emetine alone, aspiration, with its attendant hazards, can usually be avoided. Even when the inflammatory process has reached the thoracic or abdominal wall the response to this combined therapy is frequently satisfactory, and with earlier diagnosis aspiration and drainage should rarely prove necessary.—I am, etc.,

Leeds.

R. N. TATTERSALL.

### Calculation of the Colour Index

SIR,—Dr. Arthur Jordan and Dr. Herbert Levy (July 26, p. 149) would have been wise to have studied my letter more carefully before proceeding to criticize the contents. My intention was to protest against the rather ignorant viewpoint, unfortunately so prevalent at the moment, that the colour index has had its day and should be replaced by the blunderbuss use of the haematocrit—a procedure which to most people with any experience of large-scale haematology is obviously impracticable even if it were desirable. The haematocrit has its uses, but it should be reserved for cases where a primary screening by experts carrying out routine blood counts, together with a consideration of clinical findings, has shown it to be indicated. Furthermore, I was fully aware of the various investigations of human error in calculating haemoglobin, and the figures quoted by Dr. Jordan merely confirm that 80% of trained observers are likely to produce normal values of colour index within the range of 0.90 to 1.05. The personal errors of the remaining 20% would be uncovered by the ancillary investigations which were maintained. The errors of the cell count are not relevant to this discussion as they affect the mean cell volume and colour index equally. A further point is that the haematocrit is subject to mixing errors and variations of centrifuge speed—a serious disability in these days of current cuts.

I would point out to Dr. Levy that a mean cell volume determination is not likely to give much more help in the diagnosis of pernicious anaemia than an accurately calculated colour index. In any case no pathologist of repute would be prepared to concur in a diagnosis of this disease without first examining the bone marrow and gastric contents. Inaccurate diagnosis of pernicious anaemia is unfortunately not uncommon and was referred to in a previous communication (Nov. 24,

1945, p. 741). The only remedy lies in the adoption of the procedures described in my previous letters. The value of the colour index in evaluating response to treatment lies in microcytic rather than macrocytic anaemias. It is a pity that Dr. Levy has attempted to introduce a pathologists-versus-clinicians atmosphere into the discussion; any interest shown by clinicians in these matters is welcome. There would also seem to be no justification for Dr. Jordan's introduction of the name of the late Sir Frederick Gowland Hopkins.—I am, etc.,

Liverpool.

W. K. TAYLOR.

### Spinal Pumping

SIR,—Following the annotation on "Spinal Pumping" (July 12, p. 62), Mr. J. S. Horn has pointed out (July 26, p. 147) how important it is "for Speransky's basic experiments to be checked on the widest possible scale so that his conclusions may either be rejected or further developed." With this statement we heartily agree. During the last year we have reinvestigated in our department one of the early fields covered by Speransky and his collaborators, namely, the connexions between the spinal subarachnoid space and the lymphatic system. We have been able to substantiate the main findings of the Russian school to the effect that widespread connexions do exist between this space and the paravertebral lymph nodes, particularly those in the aortico-lumbar and sacral regions; and this has been done with a technique which, we believe, departs even less from physiological conditions than does that employed by Speransky.

Our results were presented in a paper read before the Edinburgh meeting of the Anatomical Society of Great Britain and Ireland in June, and will be published *in extenso* elsewhere. Encouraged by these findings we have entered upon a reinvestigation of other basic problems raised by Speransky's provocative work.—We are, etc.,

Department of Anatomy,  
University of Bristol.

E. J. FIELD.  
J. B. BRIERLEY.

### Causalgia of the Face

SIR,—I feel I must disagree with Mr. C. H. Cullen's comments (July 5, p. 32) on my paper on "Causalgia of the Face." I could have replied to his letter sooner if it were not that owing to absence from home for a few weeks I have only just seen the number of the *Journal* in which it appeared.

Mr. Cullen states that "novocain" block of efferent sympathetic fibres below the superior cervical sympathetic ganglion would produce a temporary paralysis of these fibres in their peripheral course and so prevent their being stimulated by pressure on the superior cervical ganglion. But it is known that efferent fibres peripheral to a block remain capable of conducting impulses when directly stimulated. Even when the block is not merely a temporary one but a complete anatomical section, they remain capable of conducting impulses until such time as the fibres, cut off from their cells of origin, undergo some degree of degeneration. Lovatt Evans, in *Principles of Human Physiology*, and Samson Wright, in *Applied Physiology*, agree that nerve fibres distal to a point of section can conduct impulses for a period of three days following section; and in any case it is probable that many sympathetic fibres to the face have their cell station in the superior cervical sympathetic ganglion and so would not degenerate after section of the sympathetic chain below the ganglion. It can be seen, then, that a central "novocain" block could not have prevented sympathetic impulses being transmitted to the periphery when the ganglion was stimulated and could not have prevented facial pain being felt if this pain was in fact produced by efferent sympathetic impulses and if pain impulses were then conveyed centrally by some other pathway.

I might perhaps mention here that a number of other observations, which it is hoped will be published shortly, that I made when investigating this subject from an entirely different direction point to the same conclusion.—I am, etc.,

Belfast.

J. A. W. BINGHAM.

### The B.M.A. and World Organizations.

SIR.—It is with misgivings that one reads the approbation with which Sir Hugh Lett (July 26, p. 121) couples the name of the B.M.A. with those of the World Health Organization, the World Medical Association, and Unesco. Are his remarks endorsed by the B.M.A. executive?

A "world" organization necessarily premises a central authority, in other words, a monopoly of administrative power and the advocates of "world" organization are always discreetly silent upon the two crucial points of this matter—i.e. (1) how can a central monopoly of administrative power be anything other than a dictatorship, and (2) who is it proposed shall do the dictating?

Does not the B.M.A. pride itself upon being a democratic institution, and, if so, how does it propose to remain so while subordinating its authority to a dictatorship?—I am, etc.,

St. Germans, Cornwall.

W. H. SPOOR.

### Delay to Army Overseas

SIR,—From time to time the War Office issue addenda advertising civilian medical appointments. The closing date for applications for the majority of these appointments is past by the time these addenda reach medical officers in the Middle East. For example:

Addendum No.	Date of Issue from War Office	Closing Date for Application	Date of Receipt at District H.Q.
5	Not known	Not stated	May 5
6	Feb. 18, 1947	Appt. No. (i) June 30 " " (ii) May 1 " " (iii) March 8 " " March 31	May 5 May 17
7	Feb. 25, 1947	Appt. No. (i) April 12 " " (ii) May 24 " " (iii) March 29 " " (iv) March 29	May 5 May 17
9	March 25, 1947	" " May 19 " " June 11	May 14 June 26
11	April 17, 1947	Appt. No. (i) Nov. 30 " " (ii) June 7	July 3
13	May 6, 1947	Not stated	June 21
14	May 13, 1947		
15	May 27, 1947		

I know that representations have been made through normal Army channels with no satisfactory result. The delay in transmission does not appear to be within the Middle East theatre. As this matter operates unfavourably towards medical officers stationed in the Middle East I ask you to publish this in the hope that the War Office may regain some interest in the doctor in uniform.—I am, etc.,

TONO-BUNGAY.

### Standard of Nursing Education in the U.K.

SIR,—With reference to the Registrar of the General Nursing Council's letter (July 26, p. 149), self-disparagement is one of the British traditions and privileges, but one hopes that the General Nursing Council will not indulge excessively on this occasion. It is possible that the number of lectures given to nurses in this country is less than the number given to nurses in Canada. I do not know, neither do I know the type of lecture given in Canada. I can only say that during the war I met and served with British nurses, both of the Army and R.A.F., was nursed by nurses of the Royal Navy and in the E.M.S., and worked also with Canadian nurses and American nurses. My experience did not lead me to believe that the finished product of Britain in the form of a nurse was other than of at least equal standard to the finished product of a nurse from any other country. I will admit that Canadian and American nurses, and in particular the latter, knew a great deal about medicine, and particularly about medical psychology, but I did not think that their knowledge of nursing the sick was any better than that of our nurses.

One knows perfectly well that a medical student when he qualifies has a lot of technical book knowledge but no practical experience. It may be that a similar situation exists in regard to nursing in Canada, but the important thing for nurses is that they should have not so much a theoretical knowledge as a practical knowledge of how to nurse a patient in bed.

and it is most important that their training should be as much in the practice of nursing as in the theory of nursing. Recently correspondents have urged that less time should be given to theory in the syllabus of the General Nursing Council and more to the practical side of nursing, and it is the finished product that matters and not the standard of theoretical training.—I am, etc.,

The London and Counties  
Medical Protection Society,  
London, W.C.2.

RICHARD W. DURAND.

### State Medical Service in New Zealand

SIR.—Sir Ernest Graham-Little's report (May 3, p. 611) on Mr. A. E. Porritt's letter reminds me of the good old days in India. Distinguished visitors came out in the cold weather and returned before the advent of the monsoon with a dispassionate review of the Indian administration, and usually with a complete solution of the Indian problem. I was in the Health Department before, during, and after the inception of the scheme, but merely as an interested observer. Since my release from the N.Z. Medical Corps I have worked in it as a general practitioner.

The scheme has one serious defect. The medical gentleman who was present at the birth of the Bill was not a specialist. He did not make any provision for specialists. The ablest of our profession are devoid of any share in the medical benefits, and the public are deprived of their services. Mr. Porritt is looking at the scheme through specialist spectacles.

The scheme was launched when most of the young and active practitioners were out of the country with the Armed Forces. A number of others were employed in military duties in New Zealand. There was a serious shortage to deal with the increase of work natural to the new scheme. Some of the practitioners have returned, some are with Unrra, and there are an abnormal number in the United Kingdom on post-graduate courses. When things return to normal most of the defects complained of will disappear.

(a) I agree with Mr. Porritt that the public have an improved service. They seek advice early. There is no economic advantage in going first to the chemists, the herbalist, or the chiropractor.

(b) In most places arrangements have been made for a practitioner service for urgent cases any time during the day or night and over the week-end. The Order of St. John have been most helpful in this direction.

(c) The fact that the scheme is a fee-for-service one (Heaven protect me from a salaried service!) and that the patient has choice of doctor tends to keep the standard of medical practice high. The indifferent doctor will soon be drawing unemployment benefit. There are no inducements for a doctor to attempt work he cannot do, and every inducement to send difficult cases to a consultant or to hospital. Many hospitals are open to practitioners wishing to take up special work, and the B.M.A. have organized three-monthly refresher courses. It takes anything up to six weeks to arrange appointments with a consultant. They cannot be doing so badly.

(d) If you exclude those immigrants that have not got as far as ethics in their study of English, you will find the standard of ethics in New Zealand as high as ever.

(e) A number of newly qualified medical men are attracted by the financial lute of private practice. There remain, however, the desirable type who are prepared to sacrifice the present for the nobler future.

(f) New Zealand, if not the best-governed Dominion, is the most governed.

When we regard other walks of life, we enjoy comparative freedom.—I am, etc.,

Whangarei,  
New Zealand.

F. W. W. DAWSON.

SIR.—Dr. A. D. G. Blanc (July 26, p. 146) ascribes adverse criticisms of the New Zealand medical services (which started nearly 10 years ago) to "stalwarts of organized medicine in America and Great Britain." He would seem to have missed my letter (June 14, p. 865) in which I referred in some detail to my criticisms made by Mr. Douglas Robb, a member of the New Zealand Medical Council and a distinguished consulting surgeon. Dr. Blanc ignores the fact that both Mr. Porritt and Mr. Robb, the critics cited by me, are themselves New Zealanders. Mr. Robb's exposition, which was much the more detailed and

factual, took the form of a small book which was too long for me to summarize in my short letter, but which was ably analysed in the leading article in the *Lancet* of July 5, and reviewed in the *Journal* of July 12 (p. 57).

Mr. Robb insisted strongly on the extravagant expense of the service, the cost of which, out of all proportion to its benefits, must surely be met by the individual citizen in the form of rates and taxes, and Dr. Blanc's description of the service as "free" requires the same modification that must be made of the similar claim for the proposed Service in this country. Mr. Robb describes in detail the present health chaos in New Zealand and lists no fewer than five competing schemes which the service has now developed; Dr. Blanc mentions only one. Mr. Robb makes the significant observation that the cost of the pharmaceutical benefits exceeds the cost of all the other benefits put together, a state of affairs which would seem to suggest that the "bottle of medicine" fetish is rampant in New Zealand and has not been diminished by "universally" provided medical attendance.

A layman's description of the position in New Zealand resulting from the general imposition of the five-day forty-hour week gives a similar picture of general dislocation and discomfort caused by the practical cessation of all activities, as well as of medical, after business hours. I enclose a reprint of this article.—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE.

### History of Arab Medicine

SIR.—In the *Journal* of Feb. 1 (p. 202) Mr. I. B. George assured your readers that a "statement" by the late Dr. A. R. Neligan was "as misleading as it is incorrect, and reveals little familiarity with the history of medicine. . . ." He also assured them that, in the 14th century, the Church regarded belief in infection as heretical. I pointed out (March 8, p. 314) that the "statement" which displeased Mr. George was a brief summary of a passage in Prof. E. G. Browne's *Arabian Medicine* and noted that the Pope's own surgeon stated explicitly that the plague of 1348-9 was contagious, while, long before, a bishop of the Catholic Church had written on contagion. The tentative diagnosis I made was that Mr. George knew a good deal less than Dr. Neligan about the history of medicine. This diagnosis Mr. George has kindly confirmed (July 26, p. 151).

It is true that his first sentence suggests a graver fault than ignorance (if he really knew when he wrote that Dr. Neligan was quoting from a famous Oriental scholar, it would have been disingenuous to abuse Dr. Neligan), but I think this may be due to the syntactical difficulties of English and that the disease is simple ignorance, which a closer study of Prof. Browne's lectures should cure. Mr. George has not, I think, grasped the reason why Prof. Browne advocated further study of the writings in Arabic. It was not a hope of discovering some buried treasure of marketable value, "seeing that the whole system is based on a rudimentary Anatomy, an obsolete Physiology, and a fantastic Pathology"—a remark equally applicable to Galen's writings—but something intellectually nobler: in fact a desire to trace the spiritual kinship of men of all nations and ages of the world who faced honestly the problems of medicine. Take as an illustration the doctrine of temperaments or complexions. To us the old physiology and pathology, the elementary qualities, the hot and the cold, the moist and the dry, are just nonsense in the literal sense of the word: but Galen and Avicenna were dealing with a real problem. To modern psychologists and physicians the classification and diagnosis of human types is as important as it was to our predecessors.

Did Avicenna come nearer to the truth, or what we hold to be the truth, than Galen? Does the Arabian literature preserve elements of further-eastern thought? These are some of the questions Prof. Browne thought worth answering. For such research, he tells us, a scholarly knowledge of Greek, Latin, Syriac, Arabic, and Persian, abundant leisure, voracious and omnivorous reading are essential. Perhaps, one of these days, Mr. George may qualify himself to undertake it.—I am, etc.,

London.

MAJOR GREENWOOD.

SIR.—All matters connected with Miguel Serveto are subject to error—perhaps because of the violent religious controversies in which he was involved; so that your correspondent Mr. I. B. George (July 26, p. 151) can be excused if he writes that Servetus was burned at the stake for propounding the pulmonary circulation. Serveto was condemned in Geneva on Oct. 26, 1553, to be "brulez tout vifz" because of his Arianism, though no law existed in Geneva penalizing heresy with death. The passage in his book, *Christianismi Restitutio* (1553), alluding to the pulmonary circulation was first noticed by the surgeon Charles Bernard (1650–1711) and then published in 1694 by William Wootton (1666–1726).

Serveto's execution is a blot on the name of his principal accuser, John Calvin (1509–64). Three copies of *Christianismi* escaped judicial fire—one each in Paris, Vienna, and Edinburgh. The latter, probably, is the torn copy Calvin employed to denounce Serveto to the Roman Catholic Inquisitor through Arnays in Lyons.—I am, etc.,

Little Shelford, Cambridgeshire.

H. P. BAYON.

SIR.—I was amazed at the contents of a letter in the *Journal* of July 26 (p. 151) signed I. B. George. I shall not trespass on your space to prove how inconsequential are his allusions concerning the attitude of the "Church" towards anatomy, surgery, and anaesthetics. The idea that hospitalization and hygiene were initiated in Europe through Arab influence is of course perfectly absurd. The implication that Servetus was burned by the "Church" for heresy demands, however, unqualified contradiction. We do not know when he discovered the circulation in the lungs, which he described so clearly in the volume on the renewal of Christianity, for which he was burned at Geneva by Calvin.—I am, etc.,

Farnham Common, Bucks.

T. GERALD GARRY.

### Rotunda Bicentenary Medical Exhibition

SIR.—We read with astonishment in the *Journal* of July 19 what purports to be a report of the medical exhibition held in conjunction with the International Obstetrical and Gynaecological Congress of the Rotunda Hospital at the Mansion House, Dublin, during the week July 7–12.

The Executive Committee of the Irish Medical Exhibitors Association—a voluntary organization of medical representatives formed for the purpose of holding medical exhibitions without profit or reward—has had an emergency meeting in connexion with your report, and while it welcomes fair and instructive criticism it strongly protests against the facetious manner in which your correspondent has described the exhibition. Already dozens of letters have reached our association from doctors and exhibitors expressing indignation. We feel that you should take immediate steps to rectify this display of bad taste, and give this letter the same publicity as you have given the misstatements of facts. We invite your editorial comment.

The Exhibition consisted of 44 ethical exhibitors from the Commonwealth, U.S.A., and the Continent—each approved by the Medical Committee of the Congress. They with many of the doctors who visited our Exhibition are very surprised at the manner in which the Exhibition was reported in your *Journal*.—I am, etc.,

Dublin.

W. JONES,  
Hon. Secretary,  
Irish Medical Exhibitors Association.

SIR.—Referring to your report of the Irish Medical Exhibition in the *Journal* of July 19 (p. 106). As one of the least of the 150 members of 44 manufacturing firms I should like to record my personal protest at the derogatory reference to "bright young spellbinders." This may have been intended as a facetious remark, but it is unkind, untrue, and uncalled for. Bright possibly, young most certainly not. The great majority of the gentlemen in attendance were well over the fifty-year mark. Every one was a specialist in his own branch of work.

It would be invidious to mention names, much as I should like to do so, but it is worth noting that among these men were many who held very high qualifications in medicine, physics, and chemistry, and who were highly skilled technicians. In some cases these men have carried out most valuable work in research in biochemistry and other fields of science. To mention only a

few, there were present those who had done great work before and during the war on penicillin, sulpha drugs, paludrine, anaesthetics and anaesthesia apparatus, and x-ray equipment and technique. Among them were the principals of important firms who had flown over to put themselves at the service of the medical profession. It might amaze your correspondent, who so lightly dubbed these people bright young spellbinders, to know the great work they have done and the repute in which they are held. That is why it was untrue.

It was unkind because in every case these men had attended at very great expense and at great inconvenience and interference with their work so as to give freely and cheerfully their experience and knowledge to the members of the medical profession who might desire to avail themselves of it. If it were not that the "tools for the job" had been produced by these men, and men such as they, the success of medical treatment would not be of the high order which it has attained to-day. But the words "despite their accents" gives the clue to the reason underlying the offensive remark. Forty-three out of the 44 firms exhibiting were English, or at least British, firms, and the forty-fourth was exhibiting British and Continental manufactures. Very evidently this was enough for your correspondent to wish to belittle the whole affair and the men who had dared to invade Eire. Surely in these enlightened days science should be international and should know no boundaries, and such childish and bigoted nationalism should be abandoned and credit given to men of good will who give themselves freely to the service of others.—I am, etc.,

D. T. DICKINSON,  
The London Hospital Liguire Department.

\*\*We regret that in the brief account of the Rotunda Bicentenary Meeting (*B.M.J.*, July 19, p. 106) some observations made by our correspondent have been taken amiss by those responsible for the medical exhibition, and that exhibitors should interpret his colourful comment on their enthusiasm as being derogatory.—Ed., *B.M.J.*

### POINTS FROM LETTERS

#### Tobacco

DR. LENNOX JOHNSTON (Wallasey) writes: For 20 years Dr. A. G. Pannet has smoked, he alleges (June 28, p. 950), "purely for enjoyment," and I do not doubt that he speaks what he believes to be the truth: but no addict of a powerful drug like tobacco ever, in my opinion, administers his drug *purely* for enjoyment. He is also motivated by a desire, or rather craving, compulsive in character in the strongly addicted, to keep at bay feelings of deprivation. Dr. Pannet certainly need take no account of the therapeutic effects of tobacco, but he would do well to take thought of its toxic effects. No; smoking is not a vice: it is a drug addiction, a disease. My final exclamation (it was not a statement) referred to published figures giving our purchases of tobacco during the first six months of the American loan, but I did not state (as Dr. Pannet alleges), "One-third of the American loan is being spent on tobacco" (italics mine).

#### General Knowledge and General Practice

DR. REGINALD LAWRENCE (Wakefield) writes: On page 134 of the *Journal* of July 26 there is a review of a book under the heading "Traumatic Injury." My immediate resort to "Liddell and Scott" for the word "trauma" made me wonder whether this type of injury should be placed in the category of the "gastric stomach" (that unfulfilling joy of the consulting room) and the "cardiac heart." Will someone tell me when an injury is not traumatic?

#### Gonococcal Complement Fixation Test in India

LIEUT.-COL. S. D. S. GREVAL, I.M.S. (Calcutta), writes: In the last paragraph of his letter (March 8, p. 309) Capt. K. W. G. Heathfield states: "It is one of the many annoying features about medicine in India that many special investigations are not available, including the gonococcal complement fixation test. . . ." Complement fixation test for gonorrhoea has been undertaken in the laboratory of the Imperial Serologist, School of Tropical Medicine, Calcutta, for nearly two years. The details of the technique appeared in the *Indian Medical Gazette*, 1945, 80, 551.

#### Two Names Alike

DR. BRUCE WILLIAMSON (London, W.1) writes: I shall be very glad if you will insert a few lines dissociating myself entirely from the views expressed by my namesake from San Marino, California. I find myself being taxed by colleagues disagreeing with the opinion expressed in the original letter published in the *Journal* of June 22 (p. 950).

# Obituary

## HUBERT ARMSTRONG, M.D.

Dr. Hubert Armstrong died on June 23 at the age of 75. He was a student in the Liverpool School of Medicine, Victoria University, and obtained the M.D. in 1900 and the Liverpool M.D. in 1904. He early showed an interest in paediatrics and joined the staff of the Royal Liverpool Children's Hospital, where for many years he was one of the honorary physicians. His sound knowledge, wide experience, and his keenness made him a valuable colleague.

In the first world war he served in the R.A.M.C. with the rank of captain and was on the staff of the 1st Western General, later joining the 57th General Hospital, which was sent to France. In the earlier years of his professional life, in addition to his work at the Children's Hospital, he found time to practise as an anaesthetist. For many years he was medical officer to the Liverpool Orphanage and to the Bluecoat School, where his help was greatly appreciated.

Dr. Armstrong always took a keen interest in the British Medical Association and had been a member since 1896. In 1924-5 he was chairman of the Liverpool Division. Temperamentally he was of a rather shy and reserved disposition. He enjoyed walking, and all his friends will remember his long loping stride with his head well forward. His two main interests outside his profession and his family were photography and philately. He was particularly interested in the stamps of France, of which he had a unique collection. For the last two years of his life he was a sick man and accepted his fate with fortitude. He leaves a widow and three daughters.

Dr. JAMES EDWIN WILSON died suddenly in London on July 9. He was medical officer of health at Mansfield from 1922 to 1943. An Ulsterman, he received his medical education in Ireland, where he qualified in 1904 at the Queen's University, Belfast, subsequently taking his M.D. in 1909. During his early career he held appointments at Birmingham City Infirmary and the Northern Fever Hospital, London. Later he was in private practice in London for three years. In 1911 he entered the public health service as assistant medical officer to Lindsey County Council. After serving in France and Italy with the R.A.M.C. during the first world war, he returned to the Lindsey post for a time, and then became assistant M.O.H. at Grimsby before moving to Mansfield in 1922. He had been a member of the British Medical Association since 1904 and was honorary secretary of the old North Lincoln Division in 1922.

A. H. W. writes: It was with a feeling of great personal loss that I heard of the sudden death of Dr. J. E. Wilson. For over twenty years I was associated with him while he was M.O.H. for Mansfield. His genial bonhomie and cheerfulness made him a well-liked and popular figure in the town, where he was held in high esteem. He retired in 1943 and moved to London, where he carried out part-time duties with the Ministry of Pensions and London County Council, but he never lost touch with Mansfield. "Peter," as he was known to his friends, was a man with a strong personality, frank and outspoken. He was a firm friend, a pleasant companion, and a charming host. As a result of examining many thousands of school-children he came to the conclusion that much ill-health was due to the defective breathing, and in 1939 he published an article in the *Medical Officer* on "How to Breathe Correctly," which caused widespread interest. His passing leaves a gap among his friends which will be hard to fill, and our sympathies are extended to his wife, son, and daughter in their bereavement.

Dr. HELEN BAKER died at the Royal Free Hospital on July 8 at the early age of 39. She received her medical education there and qualified in 1932, obtaining the M.R.C.S., L.R.C.P. and the London M.B., B.S. She held several house appointments, including one at the Queen's Hospital for Children and another at Bristol Royal Infirmary, before proceeding to specialize in psychiatry. She took the London M.D. in 1938 and the D.P.M. in 1941. During and after the war years she held a post at Sutton Emergency Hospital, and although the care of her young son and daughter prevented her from doing full-time work she maintained a strong enthusiasm for, and an intense interest in, her medical work. She was hoping to resume a full-time career later. Her untimely death is a great loss to her patients and to her husband, Mr. John Peterson, and family. Dr. Baker had proved herself a natural psychia-

trist by not only showing herself to be sympathetic and enthusiastic but also by her balanced view towards this difficult specialty. She was interested not only in child guidance and the problems of psychotherapy but also in social problems generally and nursery schools in particular. She was very popular, was universally liked by her colleagues and patients, and will be sadly missed by all who knew her.

Dr. J. A. P. SHAW died on June 26 at the age of 51. He was educated at Cambridge and St. Thomas's Hospital, and qualified M.R.C.S., L.R.C.P. in 1920. He was junior ophthalmic house-surgeon, and assistant medical officer to the department of Special Diseases at St. Thomas's Hospital; he was also clinical assistant in the Children's and in the Skin Departments. He was later in charge of the Department of Special Diseases at the King Edward VII Hospital at Windsor, where he was in practice. He had been a member of the British Medical Association for 25 years.

Dr. BEAUMONT HARRY COMERFORD, who died in London on July 15, was one of the older practitioners in the West End. The youngest son of Lieut.-Col. Comerford, he was educated at Sherborne School, where he gained distinction as an athlete, winning the mile, half-mile, and steeplechase and being captain both of cricket and football for two consecutive years. He was a student of St. George's Hospital, qualifying M.R.C.S., L.R.C.P. in 1887. He obtained the Durham M.D. and the D.P.H. in 1904. He was successively senior house-surgeon, house-physician, and obstetric assistant at St. George's, and was later resident medical officer at the Chelsea Hospital for Women and for ten years clinical assistant at the Victoria Hospital for Children. Dr. Comerford was also honorary medical officer for the National Children's Adoption Society. He conducted a considerable practice for over twenty-five years in Chester Square and subsequently, until his retirement in 1939, in Ashley Gardens. By his steady common sense, shrewd judgment, and great experience he won the trust, confidence, and affection of his many patients and colleagues. During the 1914-18 war he returned to St. George's as surgeon to the out-patient department and worked there for four years without a break, in recognition of which he was appointed an honorary governor of the hospital. He married in 1905 Elizabeth Frances Shaw Woodgate, elder daughter of the late Rev. R. S. Woodgate, of Pembury Hall, Kent, and he leaves a widow and one son.

Mr. ROBERT NOEL MARTIN died after a motor accident on July 25. Mr. Martin, who was only 34, was educated at Campbell College and Queen's University, Belfast. He qualified in 1937 and was appointed house-surgeon to the orthopaedic and fracture department of the Norfolk and Norwich Hospital. He was then on the E.M.S. staff for a while before serving with the Royal Navy. He was demobilized with the rank of surgeon-commander and obtained the F.R.C.S. in 1945. When the accident occurred Dr. Martin was returning from a holiday in Antrim before leaving for Chatham, where he held an orthopaedic appointment.

## The Services

### ROYAL NAVAL MEDICAL SERVICE

Applications are invited to fill vacancies for medical officers in the Royal Navy. Candidates below the age of 28 years are preferred. They must be registered under the Medical Acts and be medically fit for service at sea and in any part of the world. No examination in professional subjects will be held, but candidates will be required to attend for interview by a selection board.

Selected candidates will be entered initially for a period of four years' Short Service. Officers who leave the Service at the end of their Short Service will be eligible for a gratuity of £600, tax free. At the end of their Short Service permanent commissions will be given at Admiralty discretion to selected officers who wish to make the Naval Medical Service their permanent career. For officers on the permanent list opportunities are available for postgraduate study to specialize, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances, and retired pay (also details concerning counting civil hospital time), and forms of application may be obtained from the Medical Director-General of the Navy, Admiralty, London, S.W.1, and from the deans of all medical schools.

The Efficiency Decoration of the Territorial Army has been conferred upon Lieutenant-Colonel (Honorary Colonel) J. P. Raban and Major H. Weir, R.A.M.C.

## Medical Notes in Parliament

### NATIONAL HEALTH SERVICE SUPERANNUATION REGULATIONS

Mr. JOHN EDWARDS, for the Minister of Health, moved on July 24 that the House approve the Draft National Health Service (Superannuation) Regulations, 1947, proposed to be made by the Minister of Health under subsection (1) of Section 67 of the National Health Service Act, 1946. Mr. Edwards said that these regulations had been fully discussed with all the representative associations concerned and he was not aware of any opposition to them. They provided a superannuation scheme on an insurance basis which would cover all employees of regional boards, executive councils, and other bodies set up under the Act, and also the practitioners providing general medical and dental services. The scheme was a contributory one based on remuneration with payment of 6% for the employee and of 8% for the employer except in the case of manual workers. The employer's contribution would be paid by the Exchequer. The benefits were substantially similar to those of the Civil Service, and provision relating to contributions was similar to that in the local government service. Benefit was based on the final average remuneration except for the practitioner, in whose case the basis was  $1\frac{1}{2}\%$  of remuneration throughout service. The pension provisions took into account the new National Insurance pension. Apart from that, there was a lump sum retiring allowance, a death gratuity for death during service, and the right to a pension for incapacity. There was also provision for an injury allowance and for a widow's pension.

Provision had also been made for interchangeability with other Government services. This would be complete between the Health Service, the Civil Service, local government, and the teaching service. Arrangements were made for transfer into and from the federated superannuation scheme for nurses and the federated superannuation scheme for Universities, as also for other interchanges. The interchange arrangements would help to secure wider experience among the staffs. The new scheme would cover a large number of persons coming from local government service and would take in a considerable number from voluntary hospitals who at the moment were subject to a variety of schemes and arrangements ranging down through moral expectations to nothing at all. Those who were now subject to the federated schemes could continue on the same conditions or could come into the new schemes and do what they liked with their policies. Those subject to other arrangements would be allowed to carry on with these if they could show that otherwise there would be undue hardship. In assessing this hardship the Ministry would have regard to any change of remuneration on the transfer. Cases in dispute would be referred to the tribunals which would be set up to deal with compensation under Section 68 of the Act. Where a voluntary hospital officer with at least ten years' hospital service who in the past had only expectations without any rights came into the new scheme, the value of the expectations in relation to past service would be assessed, and, subject to Treasury approval, a supplementary payment would be made on retirement in addition to what he earned in the new scheme.

In dealing with these provisions the Ministry intended to take a sympathetic and general attitude. It was also provided that all previous hospital service would count for qualifying purposes in the new scheme. Although this service would not count in the calculation of benefit a hospital officer might immediately become eligible for benefits some of which had minimum amounts, as, for example, the death gratuity, which had a minimum of one year's salary. The scheme would be complicated for some years by the transfer problem. It was proposed to set up a new division in the Ministry of Health to deal with this. He believed the scheme would give the staff of the new service a feeling of security.

#### Some Criticisms

Mr. RICHARD LAW doubted whether he had ever seen a Parliamentary document so complicated and so difficult to read. Some simpler guide to the regulations should be published for the benefit of the members of the new Health Service. The Conservative Opposition did not propose to divide against the regulations but had some criticism to offer and hoped that Ministers would remember so far as the National Health Service was concerned that the Act was not yet in operation and that some elements in the proposed Health Service had not yet decided whether they would come in.

On interchangeability, Mr. Law said his impression was that there was no provision for interchangeability between medical

officers of local authorities and the universities. Regulation 38 (m) dealt with the position of a practitioner, whether doctor or dentist, who had a contract with an ordinary life insurance society and was allowed under these regulations to opt out of the superannuation proposals. The health authorities would pay that practitioner, to help him to meet his premiums, the share they would have paid under the proposals. Mr. Law understood that this provision would only apply if the practitioner opted into the service on the appointed day. He said that introduced an element almost of blackmail. A manual worker might enter the service at the age of 18 and was covered from that date, and all his service from the age of 18 counted towards his pension. But the medical practitioner might not qualify until he was 23, 24, or 25. The age of qualification tended to get later. The medical practitioner was at a disadvantage because he lost anything up to five, six, or seven years by being unable to enter the service at an earlier age. Mr. Law asked what was the position of the practitioner who entered the service at, say, the age of 56. The retiring age was 65, and from 56 to 65 there were nine years, but the practitioner did not begin to qualify unless he had ten years' service. This was a real injustice and should be corrected. It might be argued that compensation for the loss of his practice should suffice for a man of 56 who entered the new service. That argument was not sound. The practitioner who was compensated for his practice in terms of money as it was to-day might find when he retired that that money was worth considerably less than it was at present.

#### Explanation and Interpretation

Dr. HADEN GUEST said the proposal had in fact been explained in the medical and technical Press and he congratulated the Press on a fine job on this very difficult subject. He hoped the Minister could assure him that interchangeability in a case such as the Industrial Health Scheme would be kept open to enable different sectors of medical work to be brought in on an equal footing. He hoped that any necessary changes could be introduced in the future to maintain the principle of interchangeability when the Health Service became a complete medical service in every respect.

Col. STODDART-SCOTT asked in what sort of cases the Minister intended to dispense with the contribution. In Regulation 9 the benefits could be passed from an insured person to his spouse and his dependants, but this regulation referred only to males. Could a female pass on the benefit to her spouse? Regulation 20 said that where someone under the age of 60 years had been ill and received a pension and was then found able to take employment that person could be sent to any part of the country to find employment where the Minister or the employing authority might think fit. That brought in direction of labour. He hoped there was no intention to have direction of male or female officers of the Ministry of Health. Regulation 24 permitted the Minister to pay contributions under any federated superannuation scheme if the policy was taken out before March 18, 1946. What happened to officer appointed after that date? Were they to lose one or two years of superannuation benefit? In Regulation 25 a reference was made to certain classes of voluntary hospital officers who "had reasonable expectations." Would the Minister precisely interpret what was meant by "reasonable expectations"? Regulation 26, if generously applied, could be a great benefit to those who transferred from the voluntary hospitals scheme to the State scheme but might have difficulty in establishing claim for superannuation. He asked whether twenty years' service in the voluntary hospitals before the appointed day would be considered as an "exceptional reason" for the benefits going to these people. On Regulation 38 (m) he pointed out that before the age of 25 a doctor or a dentist might have taken out a life insurance. Why was it necessary for the life insurance policy to be one taken out before the Appointed Day if it was to be assisted from the Ministry? He asked whether the husband of a woman doctor who was in receipt of a pension would receive a pension when she died. Where the husband and wife were both doctors and the husband died did his wife, although probably drawing a retiring pension, get a widow's pension? If both had made contributions to the superannuation scheme he saw no reason why they should not receive two pensions. It was easy for the Minister of Health to coerce voluntary hospitals, but when it came to dealing with the personnel of health services he had to show that he was interested in every aspect of their welfare.

Dr. MORGAN said that under the Asylum Officers Act a officer could retire at the age of 55 with pension. Now if retiring age was to be 65, and Dr. Morgan wanted to make sure that the officer if made to serve up to 65 would receive a pension additional to the one he would have received at 55. He wanted to make sure that if for health reasons a man was

# NOVUTOX

*Self-Sterilising*  
LOCAL ANÆSTHETIC

$\frac{1}{2}\%$ , 1% & 2% SOLUTIONS

FOR

**MINOR & MAJOR SURGERY**

Absolutely non-toxic in therapeutic doses and tolerated by even the most sensitive tissues, Novutox has the added advantage that it possesses a remarkable chemo-therapeutic action which promotes very rapid and clean healing of wounds.

*Available in:*

$\frac{1}{2}\%$ , 1%, and 2% Solutions: - - - BOTTLES of 2 ozs. and 20 ozs.  
1% and 2% Solutions: AMPOULES 2 c.c. boxes of 12 and 100  
CARTRIDGES of 2% Solution are available in boxes of 20 and 100

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreitoloxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

## THE ONE KNOWN FACTOR

Seldom does the surgeon meet with the 'normal' patient. Frequently the unforeseen adds to his difficulties. But there is one known and constant factor to reassure him at the critical moment—the dependability of Ethicon Catgut. Each Ethicon Suture is conscientiously made, meticulously tested and checked so that real uniformity is reached. Post-war Ethicon Sutures are made to standards much more stringent than the official requirements—in tensile strength, in unvarying true-to-gauge diameter, in sterility. The leadership which Ethicon have thus gained in this highly specialised work is one which they will strive always to maintain.

*You can obtain Ethicon Sutures through your usual Surgical Supply House*

## A LOGICAL DEVELOPMENT

in the treatment of  
**MENOPAUSAL PRURITUS**

*Combining* PROMPT & PROLONGED LOCAL ANAESTHESIA WITH PERCUTANEOUS STILBESTROL MEDICATION

THESE distinctive properties of MENOPAX ANTIPRURITIC CREAM bring prompt relief from irritation; soothe and heal the excoriated surfaces; and provide for a more normal nutrition of the tissues by augmenting the deficient local supply of oestrogen. Indications include: pruritus vulvae, atrophic senile vaginitis, vaginal ulceration and pruritus ani.

## designed by a gynaecologist . . .

1934 saw the first adaptation of the principle of the surgical tampon to the absorption of the menstrual flow. Designed by a practising Doctor, Tampax not only won favour with women themselves, but gained the approval of gynaecologists for its alleviation of mental stress and physical discomfort and its guarantee of hygiene and safety—the latter ensured by the patent stitching process which

makes disintegration impossible. Throughout the world today Tampax is recognised as the best form of modern sanitary protection.

If you are not receiving your copies of the new series of medical leaflets now being despatched, or require a sample packet of Tampax, please write to: Medical Inquiries, Tampax Ltd, 110 Jermy St., London, S.W.1.

*Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenial aperture would cause difficulty in insertion and withdrawal.*

## Rational Antacid Therapy

APART from those cases due to actual organic disease, the treatment of the syndrome of symptoms known as indigestion generally resolves itself into an attempt to overcome hypersecretion of acid and to soothe the irritated or inflamed gastric mucosa.

That "Alocol" possesses intrinsic qualities which render it particularly valuable as a gastric sedative and antacid is now well established. Its freedom from the constipating effect of bismuth, the laxative action of magnesium salts and the gas-forming properties of sodium bicarbonate are especially noteworthy.

"Alocol" forms with the gastric contents a colloidal jelly which has the power of adsorbing free hydrochloric acid. Its markedly soothing effect on the gastric mucosa promptly relieves pain and discomfort. It does not interfere with the normal process of digestion and is free from the danger of "alkalosis."

"Alocol" is available in Powder and Tablet form.

**POWDER.**—The normal dose is 1 gramme before and after meals.

**TABLETS.**—Each tablet contains: Alocol, 0.5 gms.; P. Sacch. Alb., 0.4 gms.; Cocoa Powder, 0.035 gms.; Excipient, q.s. The normal dose is 2 tablets before and after meals.

Complete chemical history of "Alocol," with contrasting clinical reports and supply for trial, sent free to physicians on request.

1256

compelled to retire prematurely his superannuation would be given after a proper hearing and a proper trial and exchange of medical evidence and testimony. He wanted to make sure that superannuation on medical grounds was not left as in the Post Office, where a person might be prematurely retired without having his case stated properly.

Sir HUGH LUCAS-TOOTH said quite a substantial proportion of the contributions paid by women would go to men to provide benefit for their wives in due course. If an officer were disabled doing his duty he would be entitled to a pension as of right under Regulation 5 and also eligible to a pension at the discretion of the Minister under Regulation 7. These two provisions could not be reconciled as they stood.

Dr. MORGAN said one regulation dealt with accidents and diseases in industry which came under the Industrial Diseases Act, and the other regulation dealt with a person disabled from any ordinary illness.

Mr. LINSTED congratulated the Minister in getting some 60 organizations in the medical profession to agree on this draft. That must be a record. He raised the interpretation of the word "service" for the purpose of Regulation 13. He said that doctors, radiographers, physiotherapists, and speech therapists would want to come into the public service at a late stage in their lives. These persons had little hospital service to count for superannuation. Would it be possible to extend hospital service to cover at least some of these older practitioners?

#### Concession to B.M.A.

Replying to the debate, Mr. J. EDWARDS said attention had been drawn to a gap in the provisions regarding interchangeability between the staff of local authorities and others. The Government was advised that it should not deal with the subject in these regulations, but it recognized the gap and intended, in agreement with the local authorities, to put the matter right at the first opportunity. With respect to the restriction of claims in regard to insurance policies it would be difficult to allow a different option in this from the options permitted in other cases where the Appointed Day was the operative date. The Government could not prolong indefinitely into the future the right of people to ask for these options. It had not been intended originally to have any option at all. The option was put in because the representatives of the British Medical Association asked for it.

In regard to the proposal that years should be added for the practitioner's training it was impossible for the Government to single out doctors for preferential treatment. The scheme could deal only with actual service. Doctors would enter when they were qualified at the age of 23 or 24 and could complete the full 40 years before they retired at 65, thus earning the full pension. Another point raised concerned the elderly practitioner. At the moment such a practitioner had no pension in prospect but relied on the value of his practice for support when he retired. He would not be worse off under these arrangements and would earn something in the Government's scheme, but the Government could not give special benefits because the practitioner had come in late in life. To discriminate in favour of this group would lead to difficulties in other fields. The argument that compensation based on the money values of to-day might be inadequate when the practitioner retired was common to all pension schemes, and adjustment might be necessary when there was substantial change in the value of money.

He assured Dr. Haden Guest that if at any stage the Government found the scheme was restricted in regard to interchangeability it would not hesitate to alter it. In reply to Col. Stoddart-Scott Mr. Edwards said that the allocation of pension provisions in Regulation 9 applied equally to the woman doctor. In Regulation 20 there was no intention of putting words which would give power of direction later. He agreed that the words used were a little harsh and that it might have been better to say that the Minister would not withhold a pension without offering a man a job. If a man found a job for himself later and there was any difference of opinion between the Minister and the man the Regulations provided for an appeal to a referee appointed by the Minister of Labour. The Minister wished to ensure that he was able to request people who were able to do work to do so and not to permit them to draw a pension when they were fit to work. Regulation 24 referred to March, 1946, because that was the date of the introduction of the Bill and therefore the date on which the Minister's intentions could be assumed to be known. On the other hand the same Regulation later contained a specific provision for those who entered after March, 1946, to be permitted to come in and for the Minister's discretion to be used as though the date were before March, 1946. In all normal cases that discretion would be exercised.

#### "Reasonable Expectation"

On Regulation 25, entitled "Definition of Reasonable Expectation," he did not think it desirable to define this precisely. The Ministry would go to endless pains to deal fairly with persons. Regulation 26 was not intended to deal with the person who had worked for a period of his service in a hospital. It was solely intended for the super-specialist, a man resembling the person who late in life was taken into the Civil Service at top level. It was not intended to cover people who had hospital service. With the funds at disposal the widows' pensions were the best the Government could do. It had not been able to make special arrangements under which a higher premium could be paid to secure a higher pension for a widow. This was the first time that Parliament had a national scheme with widows' pensions in it. He was sorry to say there was no pension for the widower. The woman doctor did not lose any more than the bachelor. Where a widow's pension was available it was carved out of the retiring allowance, and where there was no such pension the retiring allowance was higher in consequence. Where a man and wife were in the scheme the wife was not eligible for a widow's pension in addition to her own pension rights but got her full sum in pension.

Answering points raised by Dr. Morgan, Mr. Edwards said the Government did not intend to prevent interchangeability in the ease of a genuine technical mistake. The mental worker could go at 55 or could stay to 65. He hoped that procedures would be laid down to cover this type of case when the new negotiating machinery was established.

The Government knew that it could not foresee everything, and if experience disclosed a need for modification it would certainly modify. The scheme was not the last word but was easily the most flexible scheme there ever had been in this country and one which was to the advantage of people in the service.

The House then agreed to the Motion to approve the Draft National Health Service (Superannuation) Regulations, 1947, under Subsection (1) of Section 67 of the National Health Service Act, 1946.

## Universities and Colleges

### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College, held on July 26, Mr. W. Gilliat was re-elected President of the College. The following officers were also re-elected: *Vice-Presidents*, Sir William Fletcher Shaw and Mr. James M. Wyatt; *Honorary Treasurer*, Mr. Arthur A. Gemmell; *Honorary Librarian*, Mr. F. W. Roques; *Honorary Curator to the Museum*, Mr. Aleck W. Bourne. Mr. H. G. E. Arthure was elected Honorary Secretary.

The following candidates were elected to the Membership of the College: S. J. Aptekar, H. B. Bagshaw, G. H. Bancroft-Livingston, S. Bender, Isabella R. Bishop, J. T. S. Brown, Gwendoline E. Cockrem, J. McD. Corston, G. A. Craig, K. J. R. Cuthbert, R. W. Denziger, B. C. Dastur, Josephine A. Davidson, N. E. C. de la Hunt, W. P. G. Dickson, I. A. Donaldson, Sara M. Field-Richards, T. B. FitzGerald, J. B. Fleming, I. T. Fraser, A. M. Giles, A. McM. Graham, E. F. B. Hamilton, Lois B. Hurter, D. W. James, Eileen I. Jamieson, R. J. McC. Jamieson, D. H. Lees, M. Lipsitz, G. I. Louissson, W. Love, Joan E. W. Mackie, C. J. MacKinlay, J. T. Mair, P. Malkani, W. G. Mills, P. R. Mitchell, Mary L. Neville, E. R. Ormerod, H. G. Page, S. S. Parlee, Nancy Perry, E. E. Philipp, J. G. Pritchard, E. E. Rawlings, Elizabeth M. Rose, Dorothy M. Sator, D. A. Fletcher Shaw, D. J. N. Smith, J. Walker, Ada S. Wong.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the College, held on July 15, with the President, Dr. D. M. Lyon, in the chair, Drs. Joseph Bryant (Carlisle), T. Elliot Elliot (Leicester), J. D. Allan (Bothwell), T. F. Rodger (Glasgow), and R. W. Craig, O.B.E. (Edinburgh), were introduced and took their seats as Fellows of the College. Drs. John Craig (Aberdeen), J. McG. Rogan (Glasgow), J. M. Macfie (Edinburgh), J. C. R. Greig (Kirkcaldy), A. W. Wright (Edinburgh), Neil Mac-michael (Edinburgh), Charles Cameron (Edinburgh), and J. A. L. Gilbert (Edinburgh) were elected Fellows of the College.

Prof. R. W. B. Ellis (Edinburgh) and Drs. Simon Btsh (Tel Aviv), J. P. J. Paton (Thornhill), V. H. Wilson (London), A. J. Tinker (Johannesburg), L. F. E. Lewis (Trinidad), P. L. E. Wood (London), J. H. Goonewardene (Colombo), S. J. Fleishman (Johannesburg), A. A. Williams (Middlesbrough), A. W. B. Edmunds (Edinburgh), L. G. Woods (East London), J. C. Williams (Pretoria), A. A. Guild (Airdrie), N. R. Stewart, jun. (British Columbia), D. C. Haig (Edinburgh), R. F. Robertson (Perth), and S. H. B. Blaikie (London) were elected Members of the College.

No. 29

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 19.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis

The two maps here reproduced give some indication of the geographical distribution of cases in the present epidemic and in the outbreak in 1938. The first map shows the distribution by counties of 423 cases notified during the four weeks ending July 19, 1947. The other map shows the distribution over a period of six weeks at a comparable phase in the outbreak of

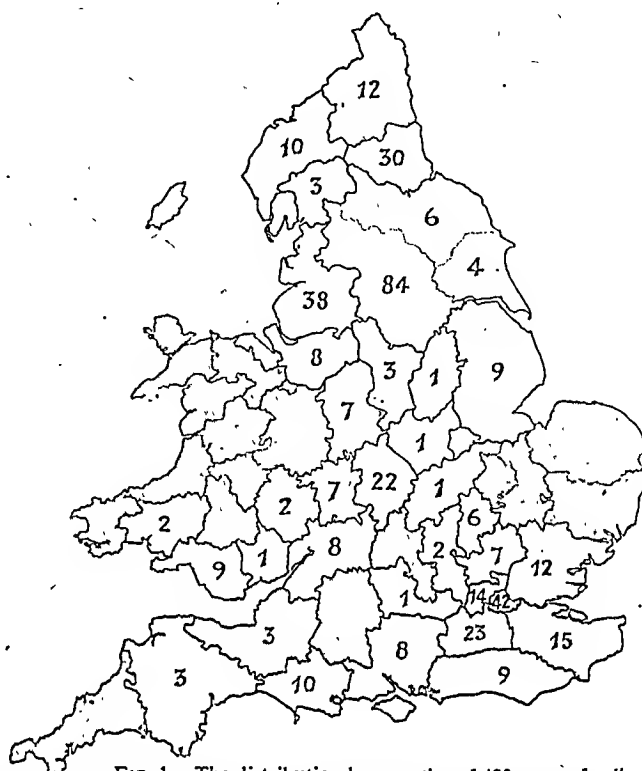

FIG. 1.—The distribution by counties of 423 cases of poliomyelitis notified during the four weeks ending July 19, 1947. The stippled sections of the map show the areas where no cases have been reported over this period.

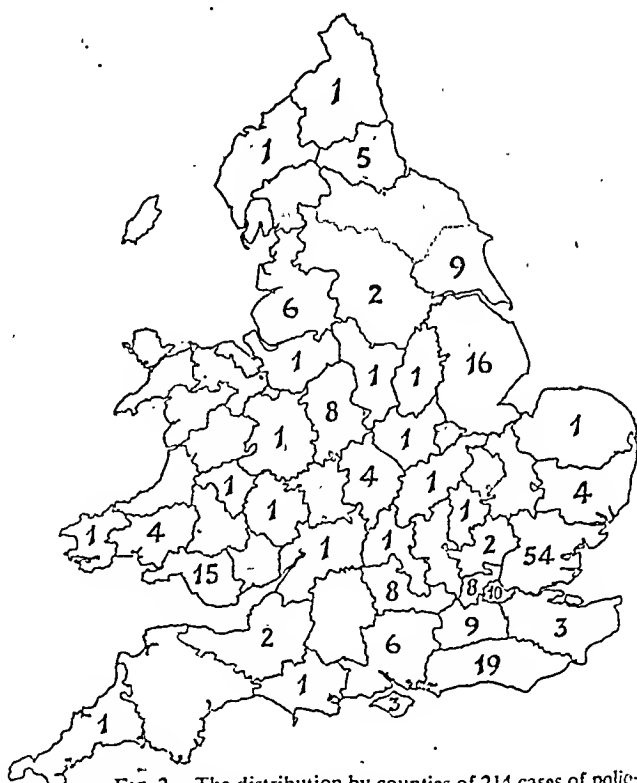

FIG. 2.—The distribution by counties of 214 cases of poliomyelitis notified during the six weeks ending Aug. 13, 1938. The stippled sections of the map show the areas where no cases had been reported over this period.

1938. It will be recalled that this year there were 31 notifications in the week ending June 14. Prevalence has been unusually low since 1938, and in general notifications have not risen above 30 a week, nor has a significant rise appeared until the end of July. It was therefore thought that it would be useful to compare the distribution for the four weeks ending July 19 this year with the six weeks ending August 13, 1938.

The notifications of poliomyelitis for the week ending July 26 in England and Wales numbered 302, against 177 in the previous week. The gradient in the curve of incidence has become somewhat steeper, and there is nothing to suggest that the peak has been reached. On the contrary, the number of new outbreaks brought to the notice of the Ministry of Health during the past week suggests that a further commensurate rise is to be expected.

Earlier reports had suggested a disproportionate incidence of cases with marked meningeal irritation at onset, but now the more usual and milder clinical types in which paralysis appears without striking prodromal symptoms are being found more frequently, and the steep gradient in the week ending July 26 may be an expression of late diagnosis and delayed notification.

Counties in which notifications reached double figures during that week were: London 51, Durham 20, Essex 13, Lancaster 17, Middlesex 17, Surrey 15, Warwick 20, Yorkshire West Riding 52.

Removals to infectious disease hospitals in the London area have shown a slight fall. The figures for the seven days to July 28 were 70, as against 61 for the seven days to August 4. The incidence in Lewisham, the metropolitan borough so far most affected, appears to be abating.

Although cases are widely scattered over England and Wales, the incidence is by no means evenly spread, and large tracts of the country are not yet involved. The need for prompt diagnosis and notification of first cases in these areas will be apparent. At this stage, when the disease is in the first or second generation in a locality, particular attention must be paid to close contacts, more especially if they develop a minor indisposition insufficient to restrict their movements. At the onset of an outbreak the virus is in all probability confined to the patient and his more intimate companions. Although there is uncertainty concerning the direct mechanism whereby the infection is distributed, it has of recent years become increasingly evident that spread is usually from person to person following fairly close contact with a previous case of abortive or paralytic disease during a relatively short period of infectivity commencing a few days before there is any sign of illness. During the period when infectivity appears to be at its height the virus is present in the oropharyngeal secretions. It may also be present in the bowel at the same time, but the most effective source of infection is probably the mouths of patients during the pre-paralytic phase or of persons with a subclinical attack.

The Belgian Ministry of Health is concerned about the present epidemic in this country, and has therefore cancelled a recent scheme for giving hospitality in Belgium to British children. The Save the Children Fund had made all arrangements to send 500 children for a three-weeks holiday as the guests of the Belgian people. These and similar arrangements made by other bodies have, unfortunately, had to be cancelled.

#### Polio-encephalitis

Notifications of cases of polio-encephalitis for the week ending July 26 reached 34. The figures for other weeks in July had been 9, 16, and 16, compared with a median value of one or two only during corresponding weeks in 1938-46. When significant changes in polio-encephalitis notifications began to appear it was suggested in some quarters that there might be a prevalence of an infection of the central nervous system other than poliomyelitis, but it is now certain that the bulk of notifications of polio-encephalitis relate to infections with the virus of poliomyelitis. In past years the ratio between cases of poliomyelitis and of polio-encephalitis has not varied considerably but was usually about 6 to 9:1. This year's experience is not remarkably different.

#### Paratyphoid B Outbreak

On July 19 a medical practitioner consulted the St. Albans Health Department about 6 people taken ill in a row of country cottages—Lea Valley Cottages, Wheathampstead. Investigation showed that 4 of the 6 were suffering from paratyphoid B. There had been a vague onset with headache, both frontal and occipital, stiffness of the neck, backache, and continued pyrexia. Gastro-intestinal symptoms were vague or absent. Of the 4 cases, 3 gave histories of onset about July 12, while in the remaining case the onset had been between July 1 and 4.

It was decided to undertake blood and faeces examinations of all persons living in the row of twelve cottages, as there had been a great deal of contact between families. In all, examinations were made of 69 residents and of one girl living at a distance who had been in close contact with the first patient. By July 28 a further 15 people were removed, 13 with a positive diagnosis bacteriologically and 2 with blood titres of a significant level. None of these cases admitted any symptoms before removal to hospital, but by July 30 3 of them had developed frontal headache, pyrexia up to 103° F. (39.4° C.), and mild crops of "rose spots." On July 28 one of the original patients, a woman of 48 who had been apparently making normal progress, had a sudden heart attack and died.

Water supplies (chlorinated main piped water), milk supplies (heat-treated), and foodstuffs including ice-cream have been fully tested and have shown no abnormal features. This, coupled with the grouping of the cases—6 in the first household, and 4, 5, 2, 1, 1—rather suggested that the mode of spread had been by contact with the first household. There is evidence that this family gave milk on many occasions to the two other households most affected. Visits have also been proved to the household with 2 cases, while in the two households with single cases the infection may be explained by contact of a less obvious nature, possibly by flies, which were heavily infesting most of the houses.

Further routine testing of contacts remaining at home continues. In all infected houses this consists of a Widal test and bacteriological examination of faeces and urine; in the non-infected houses the Widal test is omitted. Full co-operation has been given by the Public Health Laboratory at Luton, and the Central Laboratory now reports the organism to be of phage type 1.

#### Diphtheria Immunization Campaign

The Ministry of Health has recently taken the first steps in organizing a campaign for the late summer and early autumn which is intended to increase the proportion of infants under one year immunized against diphtheria to 75%. Suggestions for posters, leaflets, and other free publicity material are being circulated to all local authorities, together with some information about the progress of the campaign since its inauguration in 1941. In that year there were 50,797 cases recorded, with 2,641 deaths. In 1946 the corresponding figures were 18,284, with 472 deaths. Last year nearly half a million children under five years of age were immunized by local authorities, bringing the total number of children immunized since the campaign began to more than 6,600,000. It is hoped this year to immunize 590,000 babies before their first birthday, and it is suggested that "diphtheria could be eliminated as an epidemic disease if, in each year, three out of every four babies were protected before reaching their first birthday."

#### Scarlet Fever and Measles in Scotland

In the House of Commons on July 22 Mr. Westwood issued the following vital statistics for Scotland:

##### Scarlet Fever

Year	Number of Notifications	Number of Deaths
1935 .. ..	22,670	199
1936 .. ..	18,320	172
1937 .. ..	20,493	123
1938 .. ..	19,605	98
1939 .. ..	12,023	47
1940 .. ..	8,353	35
1941 .. ..	8,760	26
1942 .. ..	13,792	24
1943 .. ..	14,722	22
1944 .. ..	12,057	18
1945 .. ..	11,654	15
1946 .. ..	9,774	5

##### Measles

Year	Number of Notifications	Number of Deaths (All Scotland)
1935 .. ..	7,891	141
1936 .. ..	30,981	610
1937 .. ..	7,543	119
1938 .. ..	26,383	549
1939 .. ..	3,516	15
1940 .. ..	26,125	262
1941 .. ..	4,467	103
1942 .. ..	17,585	144
1943 .. ..	13,601	58
1944 .. ..	13,900	46
1945 .. ..	12,714	89
1946 .. ..	17,503	85

## Discussion of Table

In *England and Wales* an increase was recorded in the incidence of scarlet fever 118, acute poliomyelitis 67, and diphtheria 21, while a decrease was reported for measles 733 and acute pneumonia 26.

A small increase in the notifications of scarlet fever was general throughout the country; the largest rise was 29 in Essex. The chief features of the returns for diphtheria were an increase in Lancashire, Liverpool C.B., of 14 and a rise of 13 in Yorkshire West Riding contributed by the county boroughs. The largest variations in the returns of whooping-cough were a decrease of 50 in London and an increase of 42 in Warwickshire. A fall in the incidence of measles was fairly general; the largest declines were Yorkshire West Riding 261 and Gloucestershire 131, while the chief exceptions to the general trend were rises in Warwickshire 106, Lincolnshire 60, and Kent 53. Of the 10 cases of typhoid 4 were notified in Suffolk, Thedwastre R.D., where 9 cases occurred a fortnight earlier.

In *Scotland* decreases were recorded in the notifications of acute primary pneumonia 21, scarlet fever 20, and diphtheria 13, while the only rise of any size was poliomyelitis 12. The largest returns of poliomyelitis were Glasgow 6, Ayr County 4, Aberdeen 3. Diphtheria reached a record low level, and only 27 cases were notified.

In *Eire* the notifications of measles rose by 50 and a decrease of 20 was recorded in cases of diarrhoea and enteritis. The rise in measles was mainly contributed by Dublin C.B., where the number of cases increased from 107 to 152.

In *Northern Ireland* a small decline was recorded in the incidence of most infectious diseases.

## Quarterly Returns for England and Wales

The birth rate during the March quarter was 22.8 per 1,000, the largest birth rate for any first quarter since 1920. The infant mortality was 55 per 1,000 live births and was 11 below the average rate for the first quarters of the ten preceding years. The death rate for diarrhoea and enteritis among children under 2 was 6.0 per 1,000 live births, compared with 5.5, 3.9, 3.3, and 4.5 in the four preceding quarters. The general death rate was 17.2 and was 2.5 above the rate for the first quarter of 1946 and 2.4 above the average of the five March quarters of 1941-5.

A new feature of the returns is the inclusion of the sample inquiry into the prevalence of sickness during October, November, and December, 1946. The most important causes of sickness were: ill-defined symptoms; nervous complaints; rheumatism, all forms; colds and influenza. Of the sickness reported 94% did not cause any incapacity. The data are printed in tabular form without discussion. Caution is necessary in attempting to obtain anything more than a general impression from these figures. The sample is too small to be taken confidently as representative of the general population; 24-3 thousand people were interviewed in different localities each month.

Majority of the complaints were self-diagnosed, and the recording of them depends upon the memory of the person interviewed—the information is for the three months preceding the interview. Whether any significance can be attached to the economic grouping is a matter of speculation.

## Week Ending July 26

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 987, whooping-cough 1,924, diphtheria 174, measles 7,644, acute pneumonia 311, cerebrospinal fever 31, acute poliomyelitis 302, acute poliomyelitis 34, dysentery 61, paratyphoid 18, typhoid 8.

The Minister of Health announces that the Government will assist financially physiotherapists who wish to take a whole-time course of training as teachers of massage and medical gymnastics and/or electrotherapy. A special training course will be held in London from Dec. 1, 1947, to March 31, 1948, with one week's break at Christmas. Trainees living away from home will be eligible for a maintenance allowance of not more than 50s. a week; those living at home are entitled to not more than 26s. At the end of this 4-months course the trainee will be required to work as a pupil teacher at a school of physiotherapy approved by the Chartered Society of Physiotherapy. The candidate will then prepare for the examination held in May, 1949, and after a further period of 12 months as a pupil teacher may sit for the alternative certificate in May, 1950. Physiotherapists who wish to apply for assistance under this scheme should approach a school of physiotherapy approved by the Chartered Society.

## Medical News

## Epsom College

In the absence of Lord Leverhulme, who was abroad, Dr. Harold Spitta, the newly elected chairman of the Council, presided at the 94th annual general meeting of the Governors of Epsom College held on July 4. In moving the adoption of the Council's report, Dr. Spitta paid tribute to the merits of his predecessor, the late Mr. D. C. Bartley—member of the Council for 23 years and chairman since 1938—and stated that by his sudden death in May the Council had lost a great chairman and the College a great friend whose charm and dignity were admired by all who knew him. The Governors had also been deprived by death of the valued assistance of Dr. Arnold Lyndon, who had served the College as a member of the Council and of various committees for 20 years, during which time he seldom missed a meeting until his last serious illness in the autumn of 1946. Notwithstanding the many difficulties encountered during the past year the chairman said the progress of the school could be considered as satisfactory, and had warm praise for the head master and the bursar for so successfully overcoming the problems caused by the fuel crisis. Referring to the valuable assistance rendered by many helpers, Dr. Spitta mentioned the Governors' special indebtedness to Dr. Henry Robinson, not only for his personal contributions, but for the great part he played in raising funds and to the medical journals for their willingness at all times to draw attention to the work of the Royal Medical Foundation.

## Excerpta Medica

Of the fifteen new abstracting journals which the Dutch Excerpta Medica, Ltd., propose to issue in English two have now appeared in print, Section XII dealing with ophthalmology and Section XII with dermatology and venereology. Section XII is planned to have one yearly volume of approximately 600 pages; Section XIII, o approximately 1,000 pages. The Editors, and especially Prof Woerdeman, are to be congratulated on proceeding with such an ambitious scheme. In the first volume of each section it is intended to include abstracts of papers which appeared as long ago as 1944, 1942, or, in some cases, 1940. This is to bridge in some degree the gap which still exists in many countries where the medical literature of the war years is difficult to obtain. For the general physician *Excerpta Medica* will be found to be somewhat expensive. The smaller volumes of 600 pages a year are to cost £3 15s. *Abstracts of World Medicine* on the other hand, with approximately 1,400 pages a year, costs £3 3s. Other sections of *Excerpta Medica* are to cost £5 5s. or £6 4s. per annum. Section II Physiology, Biochemistry and Pharmacology, will run to two volumes a year and will cost £11 3s. annually, while Sections V and VI, dealing respectively with pathology and bacteriology, and internal medicine, are to cost £9 6s. for the two annual volumes. The cost of all the fifteen sections will be approximately £85 a year. *Excerpta Medica* should adequately replace the German *Zentralblätter*, which ceased publication during the war, and provide a service for specialists and for large and wealthy medical libraries.

## Blood

Two special numbers of the journal entitled *Blood*, edited by Dr. William Dameshek and published by Grune and Stratton, 381 Fourth Avenue, New York 16, N.Y., are being issued. The first on "Morphologic Haematology," published in July, contains nineteen articles (210 pages). The price is \$3.75. The second special number, devoted to "The Rh Factor in the Clinic and the Laboratory," will be published in November at the price of \$3.25.

## Birmingham Surgical Unit

The Austin Motor Company has presented the Birmingham Accident Hospital with a specially equipped vehicle fitted as an operating theatre to serve as a mobile surgical unit, staffed by a surgeon, anaesthetist, and nurse. The vehicle will be housed and maintained by the Birmingham Hospitals Contributory Association which will also provide the drivers. The unit comes into operation on Aug. 11 (telephone: MIDland 7041).

## Honorary Surgeon Dentist to the King

R. C. S. Dow, L.R.C.P.&S.Ed., H.D.D., has been appointed Honorary Surgeon Dentist to the King in Scotland, in succession to L. C. Broughton-Head, M.B., Ch.B., L.D.S., who has resigned.

## Wills

Dr. William Thomson Munro, formerly medical superintendent of Glenomond Sanatorium, Kinross, who died on March 11, left £21,250. Dr. Eric John Staddon, of Ipswich, Suffolk, who died on Jan. 22, left £33,160. Dr. William Archibald, late medical officer of health for Luton, who died on Feb. 13, left £25,587.

## COMING EVENTS

## Franco-Anglo-American Medical Society

Lord Horder will open the meeting of the British Section of the Franco-Anglo-American Medical Society, of which he is President in Great Britain, at 3.30 p.m. on Tuesday, Aug. 12, and not at 2.30 p.m. as announced last week (p. 195).

## C.M.F. Surgeons' Dinner

The annual dinner of the C.M.F. Surgeons Club will be held at Claridge's Hotel, London, W.1, on Sept. 11, at 7 p.m. The charge, exclusive of wine, is 25s. Surgeons and anaesthetists who served with the Central Mediterranean Force should apply for tickets through the Secretary of the Club, at 10, Park Square West, London, N.W.1.

## Aslib Study Group

The Association of Special Libraries and Information Bureaux has organized a study group on special librarianship, in co-operation with the Library Association, to be held at Chaucer House, Malet Place, London, W.C.1, during the week Aug. 11-16. Fees are £2 2s. for the course, or 10s. per day. Programme and application forms may be obtained from the Aslib office, 52, Bloomsbury Street, London, W.C.1.

## U.N.E.S.C.O. Conference

A conference under the auspices of U.N.E.S.C.O. has been planned to take place in October to establish a permanent Bureau of International Medical Congresses. Among the activities considered suitable for the bureau to undertake are the collecting of type cultures, improving the circulation of scientific literature, and the establishing of international stock rooms for pure substances not commercially available—e.g., radioactive isotopes and pure-line strains of laboratory animals.

## Narcotic Drugs

The Narcotic Drugs Supervisory Body of U.N. has tentatively fixed Nov. 17 as the day for its next meeting

## APPOINTMENTS

LENNANE, G. A. Q., M.B., B.Ch., Government Medical Officer, Rotorua, New Zealand.

MISS MARJORIE ROUSE is the first nutritionist to be appointed in Tasmania. She is preparing a report for the Commonwealth National Health Scheme.

Miss Rouse, who is a native of New South Wales, graduated from the Science University of Sydney in 1936, and in 1944 came to Britain with a British Council scholarship to work with the Orford Nutrition Survey. She returned to Australia in 1946.

BLAIR, E. J., M.D., M.R.C.P., Physician, New Cross Hospital, Wolverhampton.

HULL ROYAL INFIRMARY.—Honorary Physician: T. Stirling Eddie, M.B., B.S., M.R.C.P. Honorary Assistant Physician: T. Morton J. Stewart, M.D., D.C.H.

KENNEDY, D. A. V., M.B., Ch.B., M.R.C.O.G., Honorary Consulting Gynaecologist, Aldershot Hospital.

LONDON COUNTY COUNCIL.—The following appointments have been made in the Council's mental health services for duty at Maudsley Hospital: Physician, E. W. Anderson, M.D., F.R.C.P.; Senior Registrars, D. L. Davies, B.M., B.Ch., and W. Warren, M.B., B.Chir.

PLKINGTON, FRANCIS, M.B., M.R.C.P., D.P.M., Honorary Physician in Psychological Medicine, Prince of Wales's Hospital, Plymouth.

RUNWELL HOSPITAL, near Wickford, Essex.—Senior Physician, P. D. Scott, M.B., B.Chir. Assistant Physician, E. H. Cranswick, M.B., B.S.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

## BIRTHS

KERSHAW.—On July 26, 1947, at Liverpool, to Dr. Mary Cowell, wife of Dr. W. E. Kershaw, a second child—a daughter.

LEACH.—On June 1, 1947, at Crediton, to Dr. Irene Bower, wife of Capt. A. B. Leach, a daughter—Gillian Mary. Address: George Hotel, Combe Martin, Devon.

MACRAE.—On July 28, 1947, at St. Brenda's Nursing Home, Bristol, to Phyllis (née Mahy), wife of James Macrae, M.D., F.R.F.P.S., a daughter.

WILSON.—On July 26, 1947, at University College Hospital, to Lillie and Maxwell Wilson, a son—Andrew Thomas.

## DEATH

COOKE.—On July 29, 1947, at his home, "Whistler's Corner," Shalford, Guildford, after a long illness courageously fought, Cyril John Chesterfield Cooke, M.R.C.S., L.R.C.P., D.M.R.E. Funeral private.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

## Poliomyelitis and Tonsillectomy

Q.—There have recently been four cases of anterior poliomyelitis in children in this district. What interval should be allowed to elapse from the onset of the last notified case before tonsillectomy can safely be undertaken on two children (not contacts) living one mile from the outbreak?

A.—Notifications of poliomyelitis are increasing steadily and it would therefore be unwise to recommend tonsillectomy in any child who is living in an area—urban or rural—where cases are still occurring. The virus may persist in the faeces of convalescent cases for three to four weeks, and be present for the same period in the sewage of the district where cases have occurred. Tonsillectomy should therefore not be carried out for at least four weeks after the last case has been notified.

## Period in Bed after Operation

Q.—After an identical operation with a normal convalescence surgeons may vary by as much as 21 days in the period they keep their patients in bed. Has any really scientific work been done to prove which school of thought is right?

A.—The question of recumbency in bed after operation is a constantly recurring one, and over the years the pendulum swings freely from one side to another. The necessary economics of war in the United States has restored the popularity of early post-operative activity in that country—with seemingly excellent results. The outlook in this country is distinctly more conservative—probably too much so. To get every case out of bed on the first post-operative day simply shows lack of judgment and experience; to keep every straightforward appendicectomy case (especially when a gridiron type of incision has been used) in bed for a week or more is at least entirely unnecessary. A considerable amount of statistical and clinical research on the subject has been carried out in recent years in the U.S.A., and reference may be made to an article by Blodgett and Beattie (*Surg. Gynec. Obstet.*, 1946, 82, 485) in which further work is quoted. Summarized, the benefits of early post-operative rising are: maintenance of general physical strength, less painful wounds, shorter stay in hospital and economy of nursing staff owing to patients being able to care for themselves to a large extent, a decrease in wound disruption and infection, a lower incidence of pulmonary complications, and a great increase in morale.

## Milk in Schools

Q.—School-children get 1 1/3 pint (189 ml.) of milk per day. This entails an enormous amount of labour and a large quantity of milk, although, individually, the amount is insignificant. Is it worth the trouble and expense? Now that children get a balanced midday meal at school, would they not benefit as much from a lump of sugar and a multi-vitamin tablet with the meal? This would free a large quantity of milk and avoid waste, which is bound to occur through absenteeism.

A.—What is a "balanced" meal? The average school lunch is a good meal, but it supplies only about 25 g. of protein, 250 mg. of calcium, 500 i.u. of vitamin A value (mainly in the form of carotene), and 0.4 mg. of riboflavin; these are not half enough for a day. One-third of a pint of milk supplies a further 6 g. of animal protein, 220 mg. of calcium, about 200 i.u. of vitamin A (mainly preformed), and 0.27 mg. of riboflavin. The value of both school milk and school lunches is well shown in a paper by Chattaway, Happold, and Happold (*Journal*, 1946, 1, 429). It should be possible to avoid waste by organizing the collection of surplus milk for conveyance to factories. The value of vitamin tablets is doubtful (see Bransby *et al.*, *Journal*, 1946, 1, 193). School milk accounts for under 5% of the total liquid milk consumed; about 80% of this total is sold through ordinary channels at full price.

## Length of Vaccination Scratch

**Q.**—What is the Ministry of Health regulation length of scratch for vaccination?

**A.**—The Ministry of Health has not yet thought fit to lay down any regulation governing the length of the vaccination scratch. Although no "regulation length" has been prescribed by the Ministry the Vaccination Order, 1930 (S.R. and O., 1930, No. 2), stated in paragraph 7 of the third schedule (Instructions to Vaccinators under Contract) that vaccination should be done by a "linear" incision or scratch "not more than a quarter of an inch long."

## Saturated Solutions for Dispensing

**Q.**—It is said that in dispensing many doctors use a system of saturated solutions, and that 1 fluid drachm (3.5 ml.) of a saturated solution of the following chemicals contains the indicated quantity of the chemical: potassium bromide 30 gr. (2 g.), sodium salicylate 60 gr. (4 g.), sodium bicarbonate 60 gr., potassium citrate 60 gr., ammonium carbonate 12 gr. (0.8 g.). Are these figures correct, and what is the corresponding figure for sodium chloride? Is it also correct that the potassium citrate solution must have some chloroform in it "to prevent oxidation"? Does the darkening in colour which sometimes appears in the sodium salicylate solution on keeping indicate deterioration?

**A.**—The strength of a saturated solution of any pharmacopoeial substance is given in the *British Pharmacopoeia*. The quantities in the question are correct except for sodium bicarbonate, which should be 5.4 gr. (0.35 g.), and for ammonium carbonate, which should be 15 gr. (1 g.). The figure for sodium chloride is 120 gr. (8 g.). The B.P. says that potassium citrate should be kept in a well-closed container. There is no authority for adding chloroform to potassium citrate solution; this would not prevent oxidation. The darkening in colour which appears in a sodium salicylate solution does indicate some oxidation but it may not indicate very much.

## Thrombosis after Pyelography

**Q.**—Following a recent intravenous injection for pyelography of a floating kidney, a middle-aged man of active habits has developed a sclerosis of his right basilar and cephalic veins. (1) To what may the sclerosis be attributed, and may there be other patches of it in the system? (2) Is the condition likely to progress, and is there a possibility of any disablement of the arm or of a clot separating anywhere in the system? (3) What treatment, if any, is indicated?

—It is quite usual for a thrombus to form after pyelography; when, as in this case, it is extensive it shows that the patient is more sensitive to irritating intravenous injection than usual. (1) It is unlikely, without signs or symptoms, that there are more thrombosed veins in this part of the body. (2) There is as a rule no resulting disablement, because there are quite adequate collaterals to prevent oedema and other complications. Separation of the clot does not occur in these cases. (3) There is no treatment indicated except to spare the arm from effort until the condition resolves. Appearance of thromboses elsewhere would be an indication for the administration of dicoumarol.

## Pumpkin Seeds as an Anthelmintic

**Q.**—One often hears of the alleged efficacy of pumpkin pips in the treatment of taeniasis in South Africa. Recently a patient stated that he had been given, without success, two courses of treatment for tapeworm by the orthodox male fern, and then on the advice of a farmer's wife treated himself by ingesting several handfuls of these pips. What is the therapeutic agent present in pumpkin pips?

**A.**—Pumpkin seed or cucurbita (B.P.C.), or pepo (U.S.P.), has for centuries been used as an anthelmintic in the West Indies, Southern Europe, Africa, and the East. It contains about 30% of a fixed oil, an acrid resin, volatile oils, protein substances, and sugar. The resin is probably the active principle. The dose is 1 to 2 oz. (30 to 60 g.) of the dried seed, preceded by a saline purge and followed a few hours later by castor oil. It appears to be safe but unreliable. It is used for roundworm and tapeworm, especially *Taenia saginata*.

## NOTES AND COMMENTS

**Frustration of Left-handedness and Absent Knee-jerks.**—Dr. E. GALLOP (London, S.W.) writes: As always your valuable section headed "Any Questions?" contains much of interest, and this week (July 5, p. 40) there is a reference to the effect of the inhibition of left-handedness in the production of stammering which recalls the case of a young woman I had to examine as to her medical fitness to take up an appointment overseas about a year ago. She appeared to be perfectly healthy, and the only abnormality I could find was that her knee-jerks were absent—really absent. No positioning or reinforcement produced a flicker. She told me that when in the A.T.S. a veritable battery of doctors had been unable to discover why the jerk was missing. I happened to find that she was really a left-handed person and from childhood dexterity had been forced upon her. I could not help feeling that as the result of this most unnatural and gross interference with her inborn characters she had lost her knee-jerk. But it is the only case I have seen and maybe I am barking up the wrong tree.

**Bringing Up Baby.**—Dr. E. J. DENNISON (East Grinstead, Sussex) writes: The question about "Bringing Up Baby" (June 28, p. 958) did not, I think, receive quite the answer it deserved. Presuming that it was asked in all seriousness, then I suggest that the answer might be as follows: *Instance 1.*—If the baby has been fed and has received attention—i.e., wind up, dry nappy, etc.—then it should be put down comfortably and left. A baby requires peace and quiet in order to digest its food. It does not require "company" at this time, for that could only hinder and delay its digestion. *Instance 2.*—If he is picked up 1½ hours before his next meal, then obviously he will have to be "amused" for 1½ hours. Whoever picks him up cannot reasonably put him down after half an hour and expect him to amuse himself for a further hour. If the parents wish to lavish parental love upon him, as indeed they should do, then I would suggest that, at three months old, half an hour immediately before a feed is the best time to do it, and possibly for a short time after while he is bringing up his wind. Regarding not "thwarting" a baby, surely it is time somebody stamped heavily on this kind of nonsense, which is all too common these days. If life is to be bearable for anybody in the house—and, incidentally, for the neighbours, if any—then the baby must be taught, and taught early, to conform to the rules of the household—i.e., meals at certain times, sleep at certain times, and so on—which everybody else follows as a matter of course; just as, when it grows older, it should be taught the rules of ordinary life in the outside world rather than be left to find them out the hard way for itself. Only by doing these things can the parents hope to retain the respect and friendship of their child as he grows up. An unthwarted baby will grow into an unthwarted child, and thence into an unthwarted adolescent and adult. It would be very easy—and very often, I suspect, not incorrect—to trace a number of our present-day troubles—juvenile crime particularly, but also some adult crimes, divorces, strikes, and so on—to an unthwarted babyhood in the person or persons responsible. Certainly the falling birthrate, which happily at the moment shows a temporary check, is partially due to this mistaken idea that a baby should not be thwarted. How often does one hear, "No more for us. The first one was quite enough; bother to bring up." To the parents who asked this question I would say: "Assert yourselves now as the child's guide and teacher; show him how to live in modern society, for he obviously cannot know for himself; then you may reasonably expect happiness for him and for yourselves. If you allow him to rule you, as apparently is suggested, then you are not going halfway to meet trouble: you've got it already."

## Correction

In the answer to a question about bleached bread (July 26, p. 159) reference was made to "canine distemper." This should have read "canine hysteria."

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 9 1947

## British Medical Association

### PROCEEDINGS OF COUNCIL

A brief meeting of the Council of the Association was held on July 22, immediately preceding the Annual Representative Meeting. Dr. H. Guy Dain presided.

The deaths of two former members of Council were reported—namely, Dr. D. J. Mackintosh, of Glasgow, and Dr. O. L. Robinson, of Heysham.

#### Regional Hospital Boards

The Chairman said that there was a reasonable medical representation on the new Regional Hospital Boards, but the fact that only 27 B.M.A. nominees were appointed out of 85 nominated afforded an enlightening preview of what was meant by "consultation." Dr. Talbot Rogers considered that the number of people appointed to the Boards was too small in view of the necessity for appointing several subcommittees. Mr. R. L. Newell did not agree; the Boards, in his view, should be largely concerned with policy, leaving detail to local management committees. Use should be made of co-option.

#### The Askwith Scales

Dr. J. Fenton, chairman of the Public Health Committee, in bringing forward a special resolution on the remuneration of public health medical officers, reminded the Council of the recent history of negotiations on the Askwith scale. There had been widespread dissatisfaction among the officers concerned at the interim revision in March, 1946, many officers not benefiting at all from the recommendations. At a recent conference the utmost that the local authority associations would agree to was to increase to 20% the interim award of 10% for the category whose Askwith minimum commencing salary exceeded £1,000. No increase was offered for the other categories, whose interim awards remained at 20% and 30% respectively. It was thereupon resolved to recommend to the Council that, unless the associations agreed to a sufficient and satisfactory increase over the 1929 Askwith minimum levels, no advertisements should be accepted from any local authorities which did not agree to remuneration conforming to the Association's suggestions at the conference. After this recommendation had been tabled, however, a further letter had been received intimating the willingness of the local authority associations to reopen the matter at a conference to be held the following week, provided the recommendation was withdrawn. The Public Health Committee had met on the previous day and had agreed to propose to the Council that the recommendation in question be deferred, and that the Chairman of Council and the Chairman of the Public Health Committee be authorized to take action, including the conclusion of an agreement, or, in the absence of an agreement, any other necessary action.

The revised recommendation in these terms was agreed to unanimously by the Council.

#### Ethical Proceedings

It was agreed on the motion of Dr. N. E. Waterfield, chairman of the Central Ethical Committee, that a joint ethical committee be set up representing the British Medical Association, the British Dental Association, and two other dental bodies to discuss mutual ethical considerations and complaints made by a member of one profession against a member of the other. The terms of reference of the joint committee were also agreed to.

After due consideration the Council, on a report from the Central Ethical Committee, resolved to expel a member of the Association on the ground that his conduct was deemed detrimental to its honour and interests, and that he had wilfully and persistently failed to comply with the regulations.

#### Remuneration of Visiting Staffs

Mr. R. L. Newell presented a report from the B.H.A. and B.M.A. Liaison Committee on the remuneration of visiting staffs of voluntary hospitals. Dr. F. Gray said that the real point to be considered was whether it was worth while to press for payment to visiting staff during the short period of a year before the Act came into operation, bearing in mind that any payment likely to be made would be inadequate, and as such would have a gravely prejudicial effect on the remuneration for many years to come. The Council had before it a draft letter and agreed that this, preferably in conjunction with the British Hospitals Association, with any appropriate modification, should be issued for circulation to voluntary hospitals.

#### Other Business

The Chairman of Council was authorized to forward a suitable letter to nine honorary secretaries who have lately relinquished office and whose services were considered worthy of special recognition.

Mr. H. S. Souttar presented the report of the Science Committee, with recommendations, which were adopted, for the award of the Ernest Hart and Walter Dixon scholarships and four ordinary research scholarships. It was agreed that the income from the bequest by the late Mr. E. A. Insole of just over £5,000 should be applied to the biennial award of a scholarship to the value of £250 for research into the causes and cure of venereal disease.

On the recommendation of the International Relations Committee the period during which the fund of £1,000 authorized for B.M.A. lectures abroad might be utilized was extended until July, 1948. It was stated that two further lecture series were being arranged in Denmark, one in Norway, and one in Spain, and that one was contemplated in Holland.

The Council acceded to a request by the British Medical Students Association for official patronage and a certain amount of financial and other support for an international clinical congress which that association is organizing in July, 1948, in Oxford, Birmingham, and London. It was stated that 200 delegates from 70 different countries would be invited.

The Council considered a draft plan from the Berks, Bucks, and Oxon Branch concerning the purchase of practices. The plan was criticized by Dr. Vaughan Jones and Dr. Wand, and the Council expressed no opinion upon it.

A report from the Industrial Medicine Committee, presented by Dr. Vaughan Jones, contained no recommendations but set forth the considered view of the Committee on questions arising under the Disabled Persons (Employment) Act, in particular the appointment of medical interviewing committees.

### First Meeting of New Council

A formal meeting was held at the end of the Annual Representative Meeting on July 24. New members or members returning to the Council after an interval are Sir Lionel Whitby (President-Elect), Dr. A. Beauchamp, Dr. T. H. Crozier, Dr. P. J. Gibbons, Dr. R. G. Gordon, Dr. J. G. M. Hamilton, Dr. W. Jope, and Dr. T. W. Morgan.

The Council unanimously re-elected Dr. H. Guy Dain to the chairmanship.

The Council members of standing committees were elected, and the Special Committees which had not discharged their reference—twenty-five of them—were continued, in some cases with slight changes in membership. The nomination of members of the Central Medical War Committee was agreed to, and Mr. A. Stavcley Gough and Dr. F. Gray were reappointed representatives of the Association on the Council of the Society of Medical Officers of Health.

## CONSULTANTS ROLL, PART-TIME CONSULTANTS ROLL, AND SPECIAL GROUPS OF MEMBERS OF THE ASSOCIATION

It is apparent that there are throughout the country a number of members who are eligible for inclusion in the Association's Consultants Roll, Part-time Consultants Roll, or one of the Special Groups of members, but who have omitted to make the necessary application. The Consultants and Specialists Committee is anxious that these Rolls should be fully representative of consultant and specialist members of the Association and wishes attention to be drawn to the following particulars of membership.

### I. Consultants Roll and Part-time Consultants Roll

These are electoral rolls for the appointment to the Consultants and Specialists Committee of representatives of those members of the Association who are engaged whole-time or part-time respectively in some branch of consultant or specialist practice.

The Consultants Roll is divided into 17 regions covering England, Wales, Scotland, and Northern Ireland, and from it 20 members are elected to the Consultants and Specialists Committee. Prospective members of the Roll must sign a declaration that they are not engaged in general practice in any form but are practising exclusively as consultants or specialists and are not officers on the active list of the Navy, Army, or Air Force.

Admission to the Part-time Consultants Roll is open to those members of the Association who, although engaged in general practice, devote some part of their time to consultant or specialist practice. From this Roll five members are elected on a national basis to the Consultants and Specialists Committee.

Admission to the Rolls is by individual application and approval by the Consultants and Specialists Committee, subject to appeal to the Council.

### II. Special Groups of Members

These are Groups of members who have distinctive professional interests and who, by reason either of their paucity of numbers or of their local distribution, are unable to obtain

adequate representation of those interests through the Division and Branches. Inclusion of members of the Association in Group must be decided by the Group committee concerned upon receipt of individual applications. At present there are ten such Groups, namely:

*Group of Anaesthetists*, composed of members of the Association engaged predominantly in the practice of anaesthetics.

*Consulting Pathologists Group*, composed of those members of the Association (not being members of the public health service) working in an institutional or private pathological laboratory, engaged in examining and reporting on specimens for clinical purposes.

*Group of Dermatology*, composed of members of the Association who are engaged predominantly in the practice of dermatology.

*Group of Full-time Non-professorial Medical Teachers, Laboratory or Research Workers*, composed of those members of the Association engaged full-time as non-professorial medical teachers, laboratory or research workers.

*Ophthalmic Group*, composed of those members of the Association engaged predominantly in the practice of ophthalmology.

*Group of Orthopaedic Surgeons*, composed of those members of the Association engaged predominantly in the practice of orthopaedic surgery.

*Group of Practitioners of Physical Medicine*, composed of those members of the Association who have specially studied the values of physical methods in the prevention and cure of disease, and whose practice is devoted predominantly to the application of those methods.

*Group of Practitioners of Psychological Medicine*, composed of those members of the Association engaged predominantly in the practice of psychological medicine.

*Radiologists Group*, composed of those members of the Association engaged predominantly in the practice of radiology.

*Spa Practitioners Group*, composed of those members of the Association who regularly prescribe the mineral waters of the spas in which they reside, or who are on the staff of a hospital or clinic where the use of the local mineral waters is part of the routine treatment.

Each of these Groups appoints by election a committee which conducts the business of the Group. The Group committee considers the opinions expressed at the meetings of the Group and may also take the opinion of the Group members by poll. Its findings are placed before the Consultants and Specialists Committee, upon which it is represented, and through it before the Council and the Representative Body.

Members who feel that they are eligible for membership either the Consultants Roll, or the Part-time Consultants Roll, or one of the Special Groups are invited to make application. The requisite forms may be obtained from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, W.C. In this connexion it is stressed that membership of one of the Special Groups does not necessarily preclude membership of the Consultants Roll or the Part-time Consultants Roll, nor does admission to membership to either of the Rolls or one of the Special Groups entail inclusion in any other Group. An individual application should be made in each case.

## NATIONAL (WAR) FORMULARY

Notice is given by the Minister of Health concerning the third edition of the *National (War) Formulary* that insurance committees have been further informed that the date on which the new edition shall come into operation for national health insurance purposes will not, because of delay in publication, be Aug. 1, 1947. Information concerning the chief alterations to the previous edition appears at page 225 of the *Journal* this week. Later, when the operative date has been agreed, official notice of it will be given to doctors and pharmacists through the technical Press.

**CONSULTING PATHOLOGISTS GROUP COMMITTEE**

is a result of the recent ballot Dr. F. B. Smith, M.C. (Preston), as been elected by the members of the Consulting Pathologists Group to be a member of the Consulting Pathologists Group Committee.

**BRITISH HOSPITALS ASSOCIATION**

The following nominations to the Council of the British Hospitals Association from Scottish Area Committees have been adopted: Eastern Area, Lord Russell and Dr. H. J. C. Givson; J.E. Area, A. Burnett Whyte; S.E. Area, W. F. Ferguson; Northern Area, R. Gilbert; Western Area, J. D. Wyllie.

**HEARD AT HEADQUARTERS****That Microphone**

Two impressions of the Annual Representative Meeting. The standard of speaking has deteriorated since the microphone came on the scene. In years gone by, before the day of these contraptions, few speakers had any difficulty in making themselves heard in the great hall of B.M.A. House or even in larger auditoriums. Now many of them have difficulty in making themselves heard in the front row. Some of the speakers come up to the lectern, grasp the microphone in the hand, and twiddle it about. Others speak closely into it as though it were the mouthpiece of a telephone, with the result that the voice is distorted and the words cannot be distinguished six feet away. The microphone seems to cramp the style of even many of the best speakers. They are more conscious of that mechanical bulbous head immediately in front of them than of the more intelligent heads at a little distance. Once again, too, a little protest should be made against the reading of speeches. It is not by a mere arbitrary whim that that practice is condemned in Parliament. Some representatives came up to the rostrum with the most admirable and cogent speech, which they read like a lesson in church, only more rapidly, and quite failed to "get it across," whereas others, putting paper aside and relying on rough-hewn sentences, made a distinct hit.

**Chairmanship**

The other impression of the A.R.M. was the excellence of its chairmanship. Under Dr. Miller's gavel, which he brought down with a resounding blow on the table immediately the red light came on, so that the speaker stopped in some alarm and the next speaker was instantly called upon—under his gavel the meeting went with machine-like precision. Appealed to on one point, he remarked: "I think it is quite in order, but it doesn't make sense." No time was wasted in polite frills. If some people think the chair is dictatorial let them remember what a job it is to control a meeting of 300 representatives, with an agenda covering an enormous range, and with less than three days to carry it through. The various trade union assemblies do not sit nearly as long, nor register anything like the amount of business that is done in a day at the A.R.M.

**Correspondence****Nursing Shortage**

SIR.—In the important debate on the shortage of nurses at the recent A.R.M. I had not the actual figures at hand to relate this problem to its wider setting. The matter was, I think, referred to by another speaker, but the figures are so startling that to have quoted them from memory would have been to invite derision. They are, however, given in detail in the *Economist* of June 21, 1947, p. 963, and it is no exaggeration to say that this article, or a similar set of figures, should be seriously studied by anyone who hopes to see the present nursing shortage with clarity and in any sort of perspective. I will just quote a few lines:

"By 1948 the very severe fall in the birth rate in the early nineteen-thirties will have reduced the total number of children between fourteen and eighteen by over a million. To this natural fall in numbers must be added the young men in military service and the boys and girls between 14 and 15 who will be staying on at school owing to the raising of the school leaving age. The effect of these changes will be to reduce the number of children available for employment from just under 5,000,000 (in 1938) to just over 3,000,000—a very severe drop for a single decade. No wonder employers are feeling the pinch. There will be a further reduction in the number of young people in the labour market in the next decade, 1948 to 1958; but this will be due to the effects of legislation, not of a further fall in births. . . . The balance available for employment will, therefore, have fallen (in 1958) to just over 2,000,000 as compared with 5,000,000 in 1938."

The article finished with a characteristic understatement: "A great deal more thought has still to be given by workers and employers to the distribution of work between the different age groups." Some of this thought must obviously come from the *ad hoc* committee which it was—I am glad to say—decided to set up to consider the nursing situation, and in this case consideration of the problem apart from its statistical background will be time and thought wasted. We have to face a steadily increasing shortage of young female labour for at least ten years and no short-term policy can possibly meet the situation. My plea for a reconsideration of the waste of skilled labour caused by putting trained nurses into factories where they treat less than half a dozen minor casualties each day is frankly stop-gap, but where the scarcity is so great even a small diminution may turn an acute shortage into a famine. I hope therefore that some immediate action will be taken to stop this waste and that future policy will be based on a firm appreciation of the facts I have quoted. I might perhaps recall my letter (*Journal*, July 20, 1946, p. 98) which showed the evil results of neglecting population statistics in Palestine 27 years ago.—I am, etc.,

Winsford, Cheshire.

W. N. LEAK.

**Evidence for Spens Committee**

SIR.—The Secretary of the B.M.A. in his comments on Dr. Haler's letter (*Supplement*, July 5, p. 6) told the world the purpose of the new Spens Committee, therefore there was no need for me or anyone else to have received the inquiry from the "Evidence" Committee to be aware of its nature. He wrote: "The new Spens Committee is concerned only with the range of remuneration of consultants and specialists engaged [present tense] in a public service on a full-time basis, and not undertaking private practice."

In his commentary on my letter (*Supplement*, Aug. 2, p. 47) he alters his ground to say: "The aim is to ascertain the range of professional incomes in 1938-9 of consultants and specialists (who then practised privately and held part-time hospital appointments)."

His first statement is, as I said, confusing; his second makes it quite clear that the new Spens Committee (with the evidence of the income tax authorities as to what consultants and specialists earned in 1938-9) will suggest what the salaries of consultants and specialists will or should be in a State service. No one can object to this inquiry.

May I assure the Secretary that I am as pleased with the rise in the capitation fee as any workman is with a rise in wages. My grouse with the B.M.A. is that it has taken 34 years, two wars, and a Spens inquiry to get the fee raised from 7s. in 1912, with various rises and falls, to 15s. in 1946. Having worked for 36 years and arrived at the official retiring age I cannot in law sell my practice, and what and when my compensation for capital value is to be no one seems to know. In my humble opinion the B.M.A. has been concerned with the Government in thousands of doctors being in this position to-day.—I am, etc.,

St. Osyth, Essex.

R. E. CLARKE.

**Compensation in the N.H.S.**

SIR.—The agreement for the £66,000,000 as compensation for practices appears to be most problematical and nebulous, the Minister being in the position of "Heads I win, tails you lose," and with changing conditions the doctor is the loser. The increase in present-day fees does not compensate for the increase in practice expenses, cost of living, and taxation, so the G.P. must work a larger practice to secure a livelihood, so

there will be fewer doctors in practice. But if the number of doctors as estimated in the first instance to enter the Service is reduced, compensation will be proportionately less, so that the increased practice will receive the same compensation as if it had remained static. Further, panel fees have risen by approximately 50% and private fees by 20% to 40%.

Were the sale of practices unrestricted, the above two factors would lead to an increased capital value, which will be lost under the Act. We bought the pig in the poke. We thought that goods would become more plentiful and cheaper in the post-war years, with a substantial reduction in taxation, while the Government knew that their planned spendthrift policy must be followed by reverse conditions.—I am, etc.,

London, E.C.4.

R. A. MURPHY.

### B.M.A. LIBRARY

The following books have been added to the Library:

- Appleton, A. B., Hamilton, W. J., and Tchaperoff, I. C. C.: *Surface and Radiological Anatomy*. Second edition. 1946.
- Berg, C.: *Deep Analysis: the clinical study of an individual case*. 1946.
- Bertwistle, A. P.: *A Descriptive Atlas of Radiographs*. Sixth edition. 1946.
- Cantonnet, A.: *L'Ophtalmologie du Praticien*. Ninth edition. 1946.
- Carington, W.: *Telepathy: an outline of its facts, theory and implications*. Third edition. 1946.
- Cowdry, E. V.: (Editor): *Problems of Ageing*. Second edition. 1942.
- Cox, H. E.: *The Chemical Analysis of Food*. Third edition. 1946.
- Curtis, A. H.: *Textbook of Gynecology*. Fifth edition. 1946.
- Davis, L.: *Principles of Neurological Surgery*. Third edition. 1946.
- Dilling, W. J., and Hallam, S.: *Dental Materia Medica, Pharmacology and Therapeutics*. Third edition. 1946.
- Dukes, C. F.: *Bacteria in Relation to Nursing*. 1946.
- Dyke, S. C. (Editor): *Recent Advances in Clinical Pathology*. By various authors. 1947.
- Feinberg, S. M.: *Allergy in Practice*. With the collaboration of O. C. Durham and C. A. Dragstedt. 1946.
- Fletcher, E.: *Medical Disorders of the Locomotor System including the Rheumatic Diseases*. 1947.
- Handfield-Jones, R. M.: *Surgery of the Hand*. Second edition. 1946.
- Jervis, Sir John: *On the Office and Duties of Coroners: with forms and precedents*. Eighth edition. By W. B. Purchase. 1946.
- Joe, A.: *The Acute Infectious Fevers*. 1947.
- Katz, L. N.: *Exercises in Electrocardiographic Interpretation*. Second edition. 1946.
- Keers, R. G., and Rigden, B. G.: *Pulmonary Tuberculosis*. Second edition. 1946.
- Kershaw, J. D.: *An Approach to Social Medicine*. 1946.
- King, E. J.: *Micro-Analysis in Medical Biochemistry*. 1946.
- Klyne, W.: *Practical Chemistry for Medical Students*. 1946.
- Le Vay, A. D.: *A synopsis of Orthopaedic Surgery*. 1947.
- Mason, R. L., and Zintel, H. A. (Editors): *Preoperative and post-operative Treatment*. Second edition. 1946.
- Matthews, D. N.: *The Surgery of Repair, Injuries and Burns*. Second edition. 1946.
- Montagu, M. F. A.: *Adolescent Sterility*. 1946.
- Oakes, L., and Pennett, A.: *Materia Medica for Nurses*. Second edition. 1947.
- Oppenheimer, J. M.: *New Aspects of John and William Hunter*. 1946.
- Pattern, B. M.: *Human Embryology*. 1946.
- Pavel, I.: *Les Icères: moyens d'exploration, symptômes, physiopathologie, thérapeutique*. Second edition. 1944.
- Peel, A. A. F.: *Diseases of the Heart and Circulation*. 1947.
- Peel, J. H.: *Textbook of Gynaecology*. Second edition. 1946.
- Percival, G. H., Drennan, A. M., and Dodds, T. C.: *Atlas of Histopathology of Skin*. 1947.
- Pyc's *Surgical Handicraft*. Edited by H. Bailey. Fifteenth edition. 1947.
- Sears, W. G.: *Materia Medica for Nurses*. Second edition. 1947.
- Shaw, W.: *Textbook of Midwifery*. Second edition. 1947.
- Sherrington, Sir Charles: *Selected Writings of Sir Charles Sherrington*. Compiled and edited by D. Denny-Brown. 1939.

- Wintrobe, M. M.: *Clinical Hematology*. Second edition. 1946.
- Wright, W. D.: *Researches on Normal and Colour Vision*. 1946.

By the National Health Service (Mental Deficiency) Amendment Regulations, 1947 (S.R. and O., 1947, No. 1359), the Minister of Health is substituted for the Board of Control in certain of the Mental Deficiency Regulations, 1935.

## Association Notices

### SCOTTISH COMMITTEE

1947-8 SESSION

Election of three representatives by the Group of seven Divisions comprising Orkney, Shetland, Caithness and Sutherland, Inverness, Outer Islands, Ross and Cromarty, and Argyllshire.

In accordance with the Standing Orders of the Scottish Committee nominations for these three vacancies shall be in writing and may be (a) made by a Division or (b) signed by not fewer than three members of the Group. Nomination forms have been sent to the Hon. Secretaries of the Divisions in the Group, and can also be obtained on application to the Scottish Office. If more than three members are nominated the election shall be by voting papers sent by post from the Scottish Office to each member of every Division in the Group. Nominations should be sent to me at the Scottish Office, 7 Drumsheugh Gardens, Edinburgh, not later than August 23, 1947.

E. R. C. WALKER,  
Scottish Secretary.

### Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

(1) The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

(2) Any member of the Association who is engaged in general practice is eligible to compete for the prize.

(3) The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not therefore be omitted when it bears directly on their results, their interpretations, and their conclusions.

(4) Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual General Meeting of the Association to be held in 1948.

(5) No study or essay that has been published in the medical Press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prize-winner in any year is not eligible for a second award of the prize.

(6) If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay, the decision of the Council on any such point shall be final.

(7) Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

(8) The writer of the essay to whom the prize is awarded may on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal*, or for presentation to the appropriate section of the Annual Meeting of the Association.

(9) Inquiries relative to the prize should be addressed to the Secretary.

### A.R.M. Report: Corrections

In the report of the Annual Representative Meeting (*Supplement Aug. 2*) the sub-heading "Practitioners in General Hospital Posts" (p. 39) should read "Practitioners in Junior Hospital Posts" and the word "junior" should be substituted for the word "general" in the first line of the Plymouth motion and in the third line of Mr. Mayne's supporting remarks. Sir Lionel Whitby should have been described as Regius Professor of Physic, University of Cambridge.

## THE PROBLEM OF FERTILIZATION\*

BY

LORD ROTHSCHILD

Fertilization may be defined as the incitement of the egg to development by a spermatozoon and the conveyance of paternal qualities to the egg (Wilson, 1925). The central problem in fertilization is: What is it that the spermatozoon does to the egg which transforms it from being an inert and somewhat moribund cell into a highly organized and differentiated embryo?

## Morphology of Fertilization

Usually the egg is a fairly large cell, in the case of human beings about the size of a small pin's head; this large size is often due to the presence of nutrient material within the cell. The spermatozoon is usually extremely small. It consists of a head entirely composed of nuclear material, a middle piece, the functions of which are not clearly understood, and a vibratile tail. The relative sizes of a human egg and the head of a human spermatozoon are about those of a football and a marble.

The main characteristics of the fertilization reaction are: (1) Both eggs and spermatozoa must be ripe for fertilization to take place. (2) Fertilization is specific; that is to say, crosses between different species or genera can rarely be achieved, or, if they are, the chances of a normal embryo resulting are small. (3) Fertilization is an irreversible phenomenon in nature. (4) Only one spermatozoon fertilizes an egg. (5) After adhesion of the spermatozoon to the egg surface a membrane, the fertilization membrane, is thrown off from this surface. (6) The head of the spermatozoon rotates through 180 degrees when it has passed through the egg surface. (7) The head of the spermatozoon within the egg and the nucleus of the egg travel through the cell on somewhat curved and different paths to meet in about the centre of the egg. Then fertilization merges into cell division and development.

In this brief description there are of course various omissions and generalizations to which there are exceptions. For example, some eggs are fertilized while unripe, while it is common knowledge that interspecific crosses are possible. Even polyspermy occurs on occasion without pathological results. Nevertheless, one must assume that these morphological characteristics are significant and, as such, are particularly worthy of investigation.

The first part of the fertilization reaction occurs immediately after the spermatozoon has adhered to the egg surface. It is called activation, and involves the prevention of other spermatozoa from getting in (the block to polyspermy), the elevation of the fertilization membrane, and the irreversibility of the reaction. F. R. Lillie (1912) centrifuged eggs of the marine worm *Nereis* after the spermatozoa had adhered to their surfaces, the centrifugal force tearing the spermatozoa away from the eggs. Nevertheless, the activation changes referred to above all took place, and chromosomes even started to become visible in the female nucleus.

## Permeability and the Biophysics of Fertilization

It would be surprising if unfertilized and fertilized eggs were in the same physiological condition, and one way of investigating what differences, if any, exist between them is by observing the rate at which various substances diffuse in or out of the egg through the egg surface or plasma membrane. For many years there has been a tendency to consider the unfertilized egg as being in an inhibited condition, a condition which is rectified or corrected by fertilization. After fertilization we might expect such alterations in the egg surface as would permit a greater degree of interaction between the egg and its environment. This view received some support from R. S. Lillie (1909), who believed that there might be a similarity between the effects of stimulating an egg by a spermatozoon or parthenogenetic agent and the effects of stimulating a nerve or muscle. One of the characteristics of stimulated nerve and muscle is a temporary increase in the permeability of their cell surfaces, and R. S. Lillie (1917) found the same after fertilization in sea-urchin eggs. This egg swells osmotically when immersed in diluted sea-water, and the amount of water which enters it can be measured. Lillie found that though the total amount of water which enters an egg from sea-water of known hypotonicity is the same before and after fertilization, the rate at which osmotic equilibrium is established is significantly increased by fertilization. This means that though the osmotic properties of the egg as a whole are unaffected by fertilization some change in the egg surface occurs which enables water to pass through more easily. Though sparingly ionized substances, such as water, can pass through the surface more easily after fertilization than before, it does not follow that ions, which are electrically charged, will do the same, though it is an increase in the permeability to ions which is associated with nerve and muscle reactivity. Consequently there is no reason to expect from Lillie's results that fertilization will necessarily be associated with relatively large changes in the electrical properties of the egg surface. Neither the resistance to electric current nor the voltage, if any, across the membrane need be significantly affected. The same applies to the electrical capacity, though there is a large increase in the electrical capacity of the sea-urchin plasma membrane after fertilization (Cole, 1938). Such an increase in capacity might be caused by this membrane becoming thinner, and it is interesting that, on entirely different grounds, other research workers investigating the effect of fertilization on the permeability of sea-urchin eggs to sparingly ionized substances tentatively came to the same conclusion (Stewart and Jacobs, 1936).

At the same time it has been shown on several occasions that during the fertilization reaction acid diffuses out of the sea-urchin egg (Ashbel, 1929; Borei, 1933; Runnström, 1933; Laser and Rothschild, 1939). The acid, which so far has not been identified, is a fairly strong one, and it might be expected that its diffusion out of the

\*Annual oration to the London Jewish Hospital Medical Society, given on April 17.

egg would be accompanied by appreciable electrical changes, though these would be very difficult to measure in small eggs. Several attempts have been made to measure such electrical changes, but so far the technical difficulties have proved to be so formidable that the results have been inconclusive (Rothschild, 1938; Gelfan, 1931).

The subject of possible analogies between the response of nerve or muscle to a stimulus, and that of the egg to a spermatozoon, is closely bound up with the observation that normally only one spermatozoon fertilizes an egg. What sort of change is propagated through or round the egg from the point of attachment of the fertilizing spermatozoon which prevents other spermatozoa getting in, and what manifestations of this change can be observed?

The rate of propagation of this change must be relatively fast, because a second spermatozoon cannot fertilize an egg some two seconds after the first one has initiated the fertilization reaction. This means, in the case of a sea-urchin egg, that we can perhaps set a lower limit for the speed with which this change is propagated in the egg. It is unlikely to be much slower than one millimetre per second and may be much faster. This block to polyspermy is thought to be effected long before the fertilization membrane has lifted away from the egg surface, and probably before the breakdown or dissolution of granules in the egg surface, which takes about ten seconds to be completed at room temperature and which is probably associated with the fertilization membrane reaction (Moser, 1939).

Are these changes, which occur during the fertilization reaction, of general incidence, or are they peculiar to sea-urchin eggs, upon which a great deal of the experimental work on fertilization and parthenogenesis is done? In no other eggs has the possibility of acid production on fertilization been investigated. On the other hand, experiments have been done on the permeability of eggs to water before and after fertilization. There is no significant increase in the rate of water penetration into the egg of the annelid worm *Chaetopterus pergamentaceus* after fertilization (Shapiro, 1939). Similarly there is no increase in oxygen consumption after fertilization in this egg as there is in that of the sea-urchin. Actually the rate of oxygen consumption decreases (Whitaker, 1933). It must follow that investigations on the effect of fertilization or parthenogenetic activation in altering the permeability of the egg surface to water or other sparingly ionized substances are unlikely to help in finding common denominators in the fertilization reaction throughout the animal kingdom; though this does not of course detract from their interest in the wider field of elucidating the structure of the cell membrane. This makes the investigation of other eggs from the point of view of acid production during fertilization one of the most urgently required experiments in this field.

#### Hyaluronidase

There may be about 400,000,000 spermatozoa in a human ejaculation for the fertilization of one, or perhaps two, eggs. The number of spermatozoa can be reduced a certain amount by dilution, but far less than might be expected considering the number of eggs which will be fertilized. It used to be thought that the great number of spermatozoa was necessary to make the probability of fertilization very high. In recent years it has been found that this is by no means the complete explanation, and the discovery that other factors are involved may well have a profound effect on our understanding of the fertilization reaction and also on the treatment of sterility. These discoveries have so far been restricted to mammalian spermatozoa, but they may have some bearing on fertilization in lower organisms, on which so much experimental work has to be carried out. When freshly ovulated, mammalian

eggs are surrounded by follicle cells, and it has recently been shown that mammalian testes and spermatozoa contain an enzyme, hyaluronidase, which disperses these follicle cells, or dissolves the substances that make them stick to the egg. It is obviously difficult, if not impossible, for a spermatozoon to come into contact with the egg while the latter is surrounded by these follicle cells, and they must therefore be got rid of before fertilization can take place. The fertilizing spermatozoon is not necessarily among the first lot of spermatozoa which reach the mammalian egg. Their hyaluronidase disperses the follicle cells, leaving the egg bare for subsequent spermatozoa to achieve fertilization. One reason that so large a number of spermatozoa is necessary for successful fertilization is associated with the provision of an adequate concentration of hyaluronidase to disperse the follicle cells. This has been verified by several workers in recent years by artificially inseminating and fertilizing rabbits with suspensions of spermatozoa which were too dilute for successful fertilization under normal conditions, but with hyaluronidase, extracted from dead spermatozoa, added to the sperm suspensions (McClean and Rowlands, 1942). Women have been artificially inseminated, and successful fertilization has resulted, by adding hyaluronidase (extracted from bulls' testes) to semen which previously did not cause fertilization (Leonard and Kurzrok, 1945). Various workers in this field have shown that the amount of hyaluronidase in human semen is proportional to the number of spermatozoa present, which confirms what has been said above about the vital role of this enzyme in mammalian fertilization (Joël and Eichenberger, 1945; Werthessen *et al.*, 1945).

Perhaps more interesting still is the fact that female rats can be immunized against bull testes' hyaluronidase and the immune serum prevents the eggs being denuded of their follicle cells *in vitro*. Furthermore, normal rat semen itself contains appreciable amounts of an inhibiting substance (Leonard and Kurzrok, 1945). There are two implications to this discovery. First, it may be that new methods of contraception may be developed by the use of immunized blood sera; secondly, certain cases of sterility may be due to the inhibiting effect of blood on this enzyme's activity. It is known that the bleeding which is occasionally produced during the dilatation of the cervix at the time of artificial insemination is detrimental to fertilization. Clinical experience has also shown that after normal coitus women not infrequently fail to conceive when bleeding from lesions of the cervix or uterus. It therefore seems possible that certain types of sterility previously attributed to a hypothetical spermatozoon immunity may be due to antibodies formed against hyaluronidase, such antibodies passing from the serum into the uterine fluid and preventing fertilization.

The implications of these discoveries are by no means clear when one considers that the eggs of lower organisms, such as sea-urchins, do not have follicle cells round them. Nevertheless, the number of spermatozoa per egg is still enormous. Many eggs have protein coverings round them. For example, frogs' eggs and sea-urchin eggs when laid are surrounded by a shell of jelly. It might be thought that spermatozoa are so small that they can easily get through barriers of this type, but it is not impossible that the enzyme hyaluronidase plays some part in such cases by facilitating the passage of the spermatozoon through the jelly surrounding the egg. Moreover, there is a species-specific lysin in certain mollusc spermatozoa that dissolves the protein membranes round mollusc eggs (Tyler, 1939a).

In other types of eggs, such as those of the trout, there is a special channel in the outer covering of the egg through which the spermatozoon goes to effect fertilization. Even

in such cases an enzyme or lysin of the hyaluronidase type might play a part. Spermatozoa are usually thought to bore their way actively into eggs, but in general this does not seem to be the case. The spermatozoon is often passively absorbed, once it adheres to the egg surface. It is not difficult to imagine that an enzyme of the hyaluronidase type might be necessary for the spermatozoon to pass through the protein surface of the egg.

### Fertilizin

One of the most interesting but complicated phenomena associated with the fertilization reaction, at any rate in marine invertebrate eggs, is the appearance of a substance known as fertilizin in the medium round unfertilized eggs. The existence of this substance was first demonstrated by F. R. Lillie (1913), and subsequent researches have shown that it has two main properties. First, suspensions of spermatozoa maintain a higher rate of metabolism and mechanical activity in the presence of these "egg secretions" than in sea-water in which they are not present. Secondly, in the presence of fertilizin spermatozoa come together in clusters which cannot be disrupted by shaking, but which disintegrate spontaneously. The phenomenon is known as agglutination. The agglutinating substance in fertilizin can be used up by spermatozoa, the amount of it in the sea-water round the eggs depending on the number of spermatozoa agglutinated.

In recent years new and important work has been done on fertilizin, in particular by Tyler and his colleagues. Tyler has advanced the theory that the jelly which is found round unfertilized sea-urchin eggs may be fertilizin, and he has produced evidence confirming this. Tyler (1941) has also shown that fertilizin is not essential for fertilization if the presence or absence of fertilizin is judged by the agglutination or non-agglutination of spermatozoa. If the jelly surrounding the eggs of the sea-urchin *Strongylocentrotus purpuratus* is removed and the eggs are washed until there is no sperm agglutination whatsoever in the sea-water round the eggs, the eggs can nevertheless be fertilized with complete success. It is, however, clear that more spermatozoa are needed when the agglutinating substance has been removed, and this suggests that, apart from the agglutinating effect of fertilizin, the sperm-activation effect referred to earlier on has a function in the fertilization reaction. By increasing the activity of the spermatozoa this substance might exert its influence by increasing the probability of any particular spermatozoon reaching and fertilizing the egg, thus reducing the total number of spermatozoa necessary to ensure a high probability of successful fertilization.

The phenomenon of sperm agglutination presents a further problem of great interest and complexity. This effect is spontaneously reversible (F. R. Lillie, 1913); but after agglutinating spermatozoa markedly lose their capacity to fertilize eggs even though their metabolism and mechanical activity are unimpaired (Tyler, 1941). Nor do they agglutinate a second time. This rather suggests that the agglutination of spermatozoa of the same species is a form of false fertilization between spermatozoa instead of between eggs and spermatozoa; or, at any rate, that there is some reaction between the surfaces of the spermatozoa which is sufficiently similar to that which occurs between an egg and a spermatozoon to alter the spermatozoon in an irreversible manner, though in other ways it is still completely normal. The idea of the "muzzled" spermatozoon provides an explanation of a phenomenon which anyone who has watched fertilization under the microscope has observed—that spermatozoa can be seen bumping up against the surface of an egg and then swimming away without having adhered and initiated the fer-

tilization reaction. Perhaps the spermatozoa which do this are the "muzzled" ones, and have been "muzzled" by the agglutinin on their way through the jelly towards the egg surface. The "muzzled" sperm concept provides a further reason for the vast number of spermatozoa needed per egg to obtain a high percentage of fertilization if fertilizin in solution acts as a barrier, in that any spermatozoon which combines with it on the way towards an egg cannot then subsequently effect fertilization (Tyler, 1941). Therefore a lot of spermatozoa are needed to get through the fertilizin barrier in the sea-water round the eggs, leaving the way clear for the fertilizing spermatozoa.

Kuhn and his collaborators extracted a substance, echinochrome A, from the ripe eggs of the sea-urchin *Arbacia pustulosa*. This substance increases the activity of spermatozoa and is considered by this group of workers to be the agent in fertilizin responsible for increasing the activity of spermatozoa (Kuhn and Wallenfels, 1939; Wallenfels, 1943), though this claim has been contested by Tyler (1939b). The chemical similarity between echinochrome and vitamin K<sub>1</sub> may be significant, particularly in view of the latter's role in blood clotting.

### Biochemistry of Fertilization

From the point of view of the fertilization reaction, an egg exists in four different conditions: unfertilized, being fertilized; fertilized; and, of course, dead. We should expect that these morphological states will be reflected in the biochemistry and, in particular, in the metabolism of the cell. Consequently Warburg's (1908) discovery that the oxygen-consumption rate of fertilized sea-urchin eggs increases by a factor of six after fertilization was hailed with enthusiasm. Naturally, it was said, the egg must respire at a greater rate when fertilized, because it is an embryo, cleaving and differentiating. In some eggs, however, respiration rates do not change at fertilization; while in others the rate actually goes down (Whitaker, 1933). In any case the oxygen consumption of unfertilized sea-urchin eggs can be increased to the fertilized level by special means such as the addition of pyocyanine, or even perhaps by an increase of temperature, without activation occurring (Korr, 1937; Laser and Rothschild, 1939). The truth is that the mere measurement of oxygen consumption is inadequate as an index of metabolic activity. To investigate the biochemistry of fertilization we must probe more deeply into the fine structure of cellular metabolism and find out the precise chemical nature of the reaction cycles measured by the disappearance of oxygen and the liberation of carbon dioxide. This, of course, applies only in those cases where the reaction depends on the availability of oxygen.

The availability of oxygen is mentioned because some eggs, at any rate, can be fertilized in the absence of oxygen. Activation may therefore be an anaerobic phenomenon. This is confirmed by the fact that activation, including acid production, can take place in the presence of cyanide, which inhibits the oxidative cycle of reactions catalysed by the cytochrome system. If activation is an anaerobic process the possibility arises that the acid which diffuses out of the egg during the fertilization reaction is a product of anaerobic glycolysis. This suggests some interesting experiments, for we know in some detail the chemical reactions which go to make up the anaerobic glycolysis cycle, and also how to cause inhibition at various points in the cycle. Of course there are anaerobic metabolic systems which are entirely different from glycolysis, which starts with the breakdown of carbohydrate and ends with the production of lactic acid or alcohol. An example is a system of the cysteine desulphurase type, which anaerobically splits cysteine into hydrogen sulphide, ammonia (a

compound containing ammonia is said to be formed by sea-urchin eggs during fertilization: Örström, 1935), and pyruvic acid.

Another line of investigation is to measure the respiratory quotient during activation, technically a very difficult experiment. There is evidence (Laser and Rothschild, 1939) that the respiratory quotient is rather low during activation, which suggests that activation is associated with the breakdown of fats or proteins rather than carbohydrates.

These facts and speculations about metabolism during the early phases of the fertilization reaction suggest that activation may be associated both with anaerobic processes and with aerobic ones involving the breakdown of fats or proteins. The latter may have an inhibitory effect on the former, including acid production. The inhibitory effects of aerobic processes on fermentation are well known, and the possibility of such a Pasteur effect in the fertilization reaction could be investigated by specific Pasteur-effect poisons such as ethyl carbylamine.

So far we have discussed only the fertilization reaction. There is the separate problem whether there is any metabolic difference between unfertilized and actually fertilized eggs. The researches of Runnström (1933) and Korr (1937) have led to the rather attractive theory that fertilization induces a cytochrome type of metabolism, while the unfertilized egg respire through a non-ferrous autoxidizable carrier of the flavin or pyocyanine type, the cytochrome being present but inactivated. The evidence for this theory is too complicated to discuss in detail here, other than to mention that cyanide is stated to have little inhibitory effect on unfertilized eggs, but a marked effect on fertilized ones. How is cytochrome inactivated in the unfertilized egg? It is well known that changes in the physical state of the egg protoplasm take place as a result of fertilization (Mirsky, 1936; Mazia, 1937; Monroy and Montalenti, 1946); these might result in the activation of cytochrome, but there is no evidence that they do. Korr and Runnström's results have recently been disputed (Robbie, 1946), and it is therefore urgently necessary to repeat the experiments, which, from a technical point of view, are comparatively simple.

## INFLUENCE OF PENICILLIN ON THE COAGULATION OF BLOOD

### WITH ESPECIAL REFERENCE TO CERTAIN DENTAL OPERATIONS

BY

Sir ALEXANDER FLEMING, F.R.S.  
F.R.C.P., F.R.C.S.

Professor of Bacteriology, University of London;  
Director, Inoculation Dept., St. Mary's Hospital

AND

E. W. FISH, M.D., D.Sc.  
Honorary Dental Surgeon, St. Mary's Hospital

Certain minor operations in oral surgery depend for their success on the organization of a firm blood clot in a cavity in bone. This is particularly the case in the operation of apicectomy, where the excision of the end of the tooth root leaves a small but appreciable cavity in the bone covered only with a thin flap of mucoperiosteum. If the clot in this cavity breaks down the sinus which forms leads down to the cut surface of the tooth root and permits it to become infected.

Since penicillin has been available it has become a common practice to introduce the powder into the cavity before suturing. Such an amount of powder may, however, represent as much as 10,000 units or more of penicillin, and a marked tendency for the clot to break down has been observed in cases so treated. Because of this, experiments were made to see whether penicillin had any action on the coagulation time of blood or on the contraction of the clot.

The first experiment was carried out with an impure commercial penicillin (sodium salt) containing 361 units per mg. Of this, 100,000 units was dissolved in 0.5 ml. of normal saline, and serial dilutions (0.25-ml. volumes) were made in normal saline, leaving one volume of normal saline as a control. Normal human blood was then taken from a vein and immediately 0.25-ml. volumes were added to each tube and mixed. The tubes were then observed and the time which elapsed before clotting took place was recorded. A later examination was made to see whether or not the clot had contracted.

It was thought that the anticoagulant effect observed might be due to the impurities in the penicillin, so the same experiment was repeated using pure crystalline sodium salt of penicillin, and in the accompanying table the results are

Table showing effect of Penicillin on Coagulation Time of Human Blood

Final Concentration of Penicillin in Blood (Units per ml.)	Coagulation Time	
	Impure Penicillin	Crystalline Penicillin
50,000	No clot in 24 hours	No clot in 24 hours
25,000	" "	" 32 minutes
12,500	" "	11 "
6,250	" 75 minutes	7 "
3,125	7 "	5 "
1,562	4 "	5 ½ "
781	—	5 "
340	—	2 ½ "
170	—	2 "
Control	2 minutes	

contrasted with those obtained with the impure salt. It will be seen that the result with crystalline penicillin differed only in detail from that with the very impure commercial product, showing that penicillin itself has a considerable retarding action on blood-clotting.

### Effect on the Contraction of the Clot

In the first experiment, with impure penicillin, it was noticed that in the tube containing 6,250 units per ml., in which clotting was much delayed, the clot did not contract. In the observation with pure penicillin the whole of the serum was drawn off after 24 hours and its volume measured. The amount of serum obtained from the control was considerably greater than that from any of the tubes containing penicillin, indicating that even so little as 340 units per ml. had some retarding effect on the contraction of the clot.

### Conclusions

These results have no bearing on the systemic application of penicillin, as the concentration of the drug in the blood is then in the region of only 1 unit per ml. or less. However, it is quite easy to introduce locally sufficient to interfere seriously with coagulation and contraction of the clot.

It would appear, therefore, that the local use of penicillin in an operation where the formation of a firm blood clot is of importance should be limited to washing out the cavity with a solution of the drug not exceeding 100 units per ml. This could, of course, be combined with intramuscular injections if there is any reason to fear wound infection by penicillin-sensitive organisms.

## IRRADIATION OF GASTRIC CANCER\*

BY

G. CRANSTON FAIRCHILD, M.R.C.S., D.M.R.E.  
*Late Morris Research Fellow and Radiotherapist, Mount  
Vernon Hospital, Northwood*

AND

ALAN SHORTER, M.B., B.S., F.R.C.S.  
*Surgeon to E.M.S., Mount Vernon Hospital, Northwood*

While encouraging progress has been made in dealing with cancers in more superficial and accessible sites, cancer of the stomach still remains a problem. It is responsible for 13,000 deaths annually in Great Britain, and 40,000 in the U.S.A. (Wilbur and Shenson, 1942)—that is, 33% of all cancer deaths in America (Mullen, 1941). But, worse still, its highest incidence in men and women is between 40 and 60 years, when they have established a place in life, a home, and a reputation; when they are most useful to their profession and their country, and most necessary to their families (Ogilvie, 1945). It is the commonest type of cancer, with the worst results from treatment, for on the average only 1-4% of all cases are alive after five years following curative surgery, and only about four months' prolongation of life can be obtained by palliative operations (Livingston and Pack, 1941).

What can be done to decrease this annual toll of valuable lives? Apart from the possibility of prevention, about which we are able to do little until we know more of the causal factors, the problem is one of diagnosis and treatment. Early diagnosis is particularly important, for we know the vast majority of patients can be cured if treated by radical surgery when the disease is localized to the stomach. But at present some 80% of cases of gastric

cancer are beyond any hope of cure by surgery alone when first brought to the surgeon (Ogilvie, 1938). In spite of the tremendous advances that have been made in the surgical treatment of this disease during recent years, radical surgery can hardly become more radical, for physiological or technical reasons. Its limitations are set by Mayo's dictum that a live patient is one of the essentials of a successful operation, and not by timidity and lack of enterprise by surgeons (Ogilvie, 1945). But what of irradiation—for post-mortem findings show that over 20% of people dying of gastric cancer have the disease still confined to the stomach and immediately adjacent lymph glands (Livingston and Pack, 1939)? Owing to the impossibility of a surgical cure in such a vast number of cases, many other forms of treatment, including irradiation, have been tried in the past, but without striking success. Hardly had Roentgen discovered x rays in 1896 when Despeignes applied them to the external irradiation of a gastric cancer.

There is no need for us to recall the different forms and combinations of irradiation applied to this viscus from then to the present day. It should suffice merely to make some general remarks on their limitations and shortcomings.

*External irradiation* fails because of the deep situation of the gastric tumour and its close relation to other vital organs—both factors tending to prevent adequate tumour dosage—and because of the high but variable radio-resistance of gastric cancer cells, possibly increased by infection. This high resistance may be only apparent, owing to limitation of the tumour dose by severe general and skin reactions. Movements of the tumour make accurate centring of the x-ray beam at repeated exposures difficult to obtain. Livingston and Pack (1941) stated that most patients will not survive long enough to benefit from prolonged external irradiation alone because of the profound state of malnutrition many of them attain.

*Contact therapy* with the Chaoul tube covers a relatively small area (2 cm. diameter) in each field with very little penetration at low voltage. Pack (1939) found that only 22% of the surface dose penetrated to 1 cm. below the surface. For comparison, Fairchild finds that 32% of the surface dose of high-intensity irradiation penetrates to 10 cm. below the surface with the technique he has been using. With the Chaoul tube bulky tumours could not be destroyed by single surface doses at one operation, but needed repeated exposures. This could be done only through some kind of fistula or pouch formation. With such a small field of 2 cm., repeated applications would be required for most inoperable tumours, with the obvious difficulty of adequate and uniform dosage. Also, such localized irradiation would have no appreciable effect on any glandular or other local spread, the presence of which is the usual reason for inoperability.

*Radon seed implantation* has the same difficulty of uniform and adequate dosage (as shown by subsequent radiography) when introduced at operation from either serous or mucous surface, or through a gastrostomy opening or the oesophagoscope. There are also dangers of haemorrhage and infection and perhaps perforation due to massive necrosis of the tumour, while the adjacent field of spread does not receive adequate irradiation.

*Intracavity irradiation* with the five-way tube described by Livingston and Pack (1941) has, they claim, the advantages of easy application, fractionation of doses, avoidance of damage to adjacent vital organs, freedom from dangers of haemorrhage, infection, and perforation, and no interference with food intake. But they had not at that time determined how effective a total dose patients would stand, the most effective fractions into which to divide the total dose, or the results as regards palliation or cure. Used

\*A paper read at a symposium on gastric cancer at a combined meeting of the Radiological Section of the Royal Society of Medicine, the Faculty of Radiologists, and the British Institute of Radiology on Dec 14, 1946.

alone it would appear not to have much effect on local spread, but combined with direct irradiation it might perhaps be used to supplement the dose reaching the centre of large gastric tumours.

Many people think that irradiation not only shortens the patient's life but also adds to his sufferings, and therefore is quite unjustifiable. While this may be true of many of the other methods of treatment we maintain that direct irradiation at high intensity has none of these disadvantages.

### Direct Irradiation

Because of the lack of any striking results from these forms of attack on gastric cancer, Fairchild (1935) first conceived the idea of direct irradiation of deep-seated tumours exposed temporarily at operation. Owing to difficulties associated with anaesthesia and the length of time required to give an adequate dose (at the rate of 40 r per minute—the maximum possible at that time) a compromise was attempted. Some cases of rectal cancer were treated by external irradiation applied posteriorly, after turning back skin-flaps over the sacrum and coccyx. By this means adequate tumour dosage was not obtained, so fractional doses were applied daily for a week or ten days. But the wounds became infected when kept open for so long, and the method was abandoned. Further progress was held up until 1944, when Fairchild and Shorter began to work out a technique for the direct irradiation of gastric cancers exposed temporarily at operation as had been originally intended, instead of merely turning back skin-flaps. Using the intensities then available (700 r to 2,000 r per minute), the method was later elaborated to deal with cancers of the oesophagus, pancreas, colon, etc.

### Advantages of the Method

1. More accurate information about the size, shape, position, and extent of the primary lesion, and any local or general spread, can be obtained at the exploratory operation than can be found out by any other methods, either clinical or laboratory. In the thorax, where we can usually make a fairly satisfactory radiological examination, the extent of a cancer is almost invariably greater than it would seem from x-ray films. So in the abdomen the growth is nearly always more extensive than can be determined by the usual examinations and investigations. According to Walters *et al.* (1942), exploratory operation is the only reliable way of deciding the correct form of treatment.

2. Biopsy specimens can usually be obtained to help confirm the diagnosis. With palpable glandular involvement this can be done safely, but incision of the tumour may spread tumour cells or lead to perforation owing to subsequent massive irradiation. Thus biopsy may not be practicable in all cases, but being able to see and feel the tumour should make the diagnosis more certain than when relying on external methods of examination alone.

3. A more accurate and effective dose of irradiation at high intensity can be given direct to the tumour and field of local spread without irradiating such a large volume of normal tissue, including vital organs and skin, unavoidable when irradiating from the skin surface. This may be of great importance in an already anaemic and cachectic patient.

4. More accurate centring of the x-ray beam is possible under direct vision than when relying on x-ray films or clinical examination alone.

5. The skin is left practically intact, and will permit further full dosage to be given externally at a later date should this be deemed necessary. Supplementary external irradiation was given later in some of our earlier cases, beginning about ten days after operation, as we felt that the initial dose was too small to cure. Some had further external irradiation after some months.

6. Various operations to relieve obstruction can be performed before the irradiation, at the same or an earlier and less exten-

sive laparotomy, such as gastrostomy for cardiac obstruction and gastro-jejunostomy for pyloric lesions. Though the obstruction may not be severe it increases owing to fibrosis of the tumour after irradiation. In hopeless cases these operations can be done without irradiation to relieve symptoms.

### Preliminary Investigations and Pre-operative Preparation

Diagnosis and localization of the tumour are achieved as accurately as possible by clinical, radiological, gastroscopic, oesophagoscopic, and laboratory investigations. The general condition of the patient is investigated as regards possibility of metastases, state of nutrition, and fitness for anaesthesia and operation.

Patients with cancer of the upper alimentary tract are often at high risks for operation or irradiation. This varies considerably with the site and type of growth, the degree of interference with nutrition, infection of the tumour or even the whole mucosa, and toxæmia from the growth. The patient with cancer at the cardia or pylorus is usually at a worse risk than the patient with a mid-gastric lesion, owing to the more profound disturbance of nutrition, even amounting to gross deficiencies of many vitally important substances. These deficiencies must be made good, before any extensive operation or intensive irradiation is carried out, by means of a high-protein, high-carbohydrate, low-fat diet, with extra fluids, iron, salts, and vitamins when necessary (Payne, 1940; Reid, 1941; Garlock, 1942; Ravd *et al.*, 1943; Wangenstein, 1943). Infection is combated by the tumour, or in the stomach generally in pyloric obstruction, by daily gastric aspiration and lavage with weak hydrochloric acid solution. Dental sepsis, so often associated with upper tract cancers, is attended to before general anaesthesia. Routine coughing and breathing exercises are begun before operation and continued as soon as possible after operation, to maintain a clear airway and good expansion of the lungs (Shorter, 1944). This is the most important measure in avoiding lung complications after upper abdominal operations, especially when the thorax is opened as well.

### Surgical Approaches

Owing to the tendency of the growth to spread along the stomach, or to lymphatics above, behind, or below the stomach, the exposure must be such as to enable the direct irradiation to be carried out in an antero-posterior plane, otherwise uniform irradiation of the tumour area would not be possible. It follows that the left transthoracic approach is unsuitable for direct irradiation even for the cardiac area and lower oesophagus (Shorter, 1946).

This may be in one or two stages (Fairchild and Shorter, 1945). (1) When there is well-marked cardiac or pyloric obstruction gastrostomy, gastrojejunostomy, or even jejunostomy may be necessary before the patient's condition can be improved sufficiently to stand the wider exposure and irradiation. This is usually done through a small upper left paramedian incision, making exploration of the tumour and the whole abdomen possible. Many cases have in this way been found unsuitable for irradiation owing to unsuspected widespread metastases. (2) When the patient's condition seems satisfactory the abdomen is explored through a different incision more suitable for extension, even into the thorax if necessary. We have usually followed this practice when the condition of the patient will allow it, so as to avoid the two operations advocated by Garlock (1941, 1942). Also it saves moving the patient between making separate incisions for the exploration and the main exposure (Churchill and Sweet, 1942a, 1942b). The form of treatment to be carried out cannot be decided upon beforehand.

so preparation must be made for all contingencies so far as is possible. The abdomen must be thoroughly explored before making an extensive exposure, especially before opening the thorax. It would seem to be unwise, and unfair to the patient, to open his thorax and divide his diaphragm before estimating carefully the extent of spread in the abdomen (Shorter, 1946).

(a) *Midline Incision.*—In our early cases the main approach was through a midline incision from the sternum, excising the xiphoid, to the umbilicus or beyond. With a narrow subcostal angle, the wound was widened by dividing each costal margin and forcibly retracting. Then the tumour was mobilized to bring it down into the open wound. This method was soon abandoned in favour of leaving the tumour *in situ* and retracting the abdominal and perhaps thoracic wall to give direct and wider exposure.

(b) *Angular Abdomino-thoracic Incision.*—For upper gastric tumours a transverse incision was made through the sixth and seventh left costal cartilages from the upper end of the midline incision, and continued round in the fifth space to the posterior axillary line. The thorax was opened and the left side of the diaphragm divided down to the oesophageal hiatus, the incision skirting round the left edge of the pericardium. This method caused less operative shock and decreased the risk of spreading the disease by lymphatic embolism, owing to decreased manipulation of the tumour. Also it gave better access to the cardiac region, though some difficulty was experienced in retracting the angular flap containing the divided left costal margin.

(c) *Oblique Abdomino-thoracic Incision.*—In our later cases this difficulty was overcome by an oblique incision across the upper abdomen, from the ninth right to the seventh left costal cartilage, in line with the outer part of the fifth left interspace. The incision was continued through the left costal margin lower down into the fifth interspace, the thorax opened and the diaphragm divided, as before. This gave a wide straight opening with much better direct access to the whole stomach.

We have found this oblique incision most useful for gastrectomy and oesophago-gastrectomy. Garlock (1946) has recently described a somewhat similar combined abdomino-thoracic approach to the lower oesophagus and cardia, but he explores the abdomen through an upper left pararectal incision, which may be continued into the thorax through the ninth left interspace.

### Points in the Operative Procedure

When operations to relieve obstruction are necessary they are done before the irradiation, and when possible in an area of the stomach not to be irradiated. Irradiation of normal viscera, so far as is possible, is avoided by displacement and packing out of the field. In our earlier cases lead screening was used to protect the skin edges of the wound. More recently we have introduced a special sterilized applicator into the wound. Sterilized oiled silk protects the field against infection during irradiation but allows accurate visual centring of the tumour in the x-ray beam. To avoid shock produced by frequent moving, a special trolley has been designed on which the patient can have both the operation and the irradiation.

### Radiological Data

The apparatus consists of two Metropolitan Vickers constantly evacuated x-ray tubes of the 250-kV type. Special modifications in the layout and in various components of this apparatus have been made, so that both tubes may be used simultaneously in treating a single lesion. This has been done to increase the intensity above that available with the standard apparatus. The lower tube has a vertical traverse only, whereas the overhead tube has a vertical and horizontal traverse. The beam of each tube can be rotated through 300 degrees in a vertical plane. With the use of radiation giving a half-absorption value

of 1.7 mm. Cu, the available surface intensity is of the order of 1,000 *r* per minute from each tube. In each case the focal skin distance is 21.7 cm. and the field 13 cm. in diameter.

*Methods of Irradiation.*—In our original method only one tube was used to administer a single dose of radiation direct to the lesion. This was followed in ten days by a further dose given through the skin. In our later cases this method was modified in an attempt to give an adequate total dose of irradiation at one exposure, with more uniform distribution, so as to avoid the necessity for subsequent external irradiation. For this purpose the overhead tube was used as before, while the lower tube, with the x-ray beam directed upwards, was arranged beneath the patient, with the canvas trolley-top alone intervening. The central ray of each beam was so directed as to pass through the centre of the lesion. In our first method, with one tube, the total initial tumour-surface dose was 500 *r*–1,200 *r*, the latter figure being chosen as a maximum because it had been effective in certain superficial lesions. Also it was thought that a larger dose might cause massive necrosis of tumour tissue, with a risk of haemorrhage and perforation, there being no precedent to indicate the probable effects of such high tumour doses given with a maximum of two to five minutes. In our second method a provisional average tumour dose of 1,300 *r* was decided on, as a minimum throughout the tumour, entailing a surface dose of 1,300 *r* from the under-couch tube and 1,600 *r* direct to the lesion from above. This latter dose is being gradually increased.

*Post-operative and Irradiation Reactions.*—Immediate reactions have been no more severe than would have been expected after the operation alone, which often involved extensive exposure of the viscera, with both thorax and abdomen widely open together, and much manipulation during isolation of the tumour. Even after giving 3,000 *r* in three minutes there has been remarkably little irradiation reaction, which has come on seven to ten days later, when the operation reaction has passed off. It has been mostly limited to nausea and anorexia, with rarely any vomiting or diarrhoea. Blood changes have been less severe than usual after external irradiation, when the dose is spread over a longer time and a far greater volume of tissue and blood is treated. Irradiation reaction has been more severe and the recovery much slower after the external irradiation given to certain of our earlier cases some months after the operation and direct irradiation, even though the patients were generally more fit for the later treatment, which was a relatively smaller dose spread over a few weeks.

### Results of Treatment

During the past two and three-quarter years 32 cases of inoperable gastric cancer have been investigated. Of these patients three refused all treatment and left hospital, and one was considered unfit for exploratory operation, being a man of 80 with a large palpable tumour of the lesser curve. The remaining 28 cases were explored. Three of these were unfit for further treatment—one due to widespread growth and poor general condition; another due to extensive residual growth and insuperable adhesions following partial gastrectomy; and the third due to extensive growth with perforation of a carcinomatous ulcer. Ten of those explored were found unfit for direct irradiation owing to too extensive growth or poor general condition, or both, and had palliative operations only.

This leaves 15 cases that were treated by direct irradiation. These can be divided into two groups—first, a group of seven cases in which the irradiation was purely palliative owing to obvious spread beyond the possible field of irradiation or to poor general condition. Of these, one is

alive and well after five weeks; one lived six months, one five months, and two four months; while the rest died sooner. In the second group of eight cases the growth appeared to be limited to an area that could be irradiated. Of these, one lived 24 months, two 15 months, one seven months, one four months, and one three months after treatment. The remaining two died within the first week—one from bilateral pulmonary collapse while the wound was being closed, the other from spontaneous pneumothorax on the opposite side four days after operation.

### Details of Cases

The following are brief details of some of our cases in chronological order, as we proceeded with and modified our technique.

*Case 1.*—A man aged 35, with carcinoma of the lesser curve, had a laparotomy on Feb. 15, 1944, via the upper midline incision, widened by division of both lower costal margins. The tumour was a large elongated flat plaque extending from 2.5 cm. short of the pylorus to the cardia; its surface was stony-hard, irregular, and with subserous spread. It measured 13 cm. vertically, 7 cm. antero-posteriorly, and 4.5 cm. thick. The rest of the stomach was normal. Spread to glands or viscera was not found. A biopsy was not made, but surgeon, radio-therapist, and pathologist were all sure of the diagnosis. The tumour was irradiated with one tube, the maximal tumour dose being 1,000 r in one minute. External irradiation was begun nine days later, amounting to a maximal tumour dose of 970 r in 12 days. The total maximal tumour dose was 1,970 r in 21 days. The tumour decreased very much in size, with marked contraction of the stomach also. The patient's appetite soon returned, and he was able to eat any food without indigestion. As his stomach became smaller it emptied more rapidly, so that he had to take small meals frequently. He gained over 2 stone (12.7 kg.) in weight after treatment, and returned to work as a newspaper reporter within six months. He was readmitted to hospital at the end of December, 1945, and died from widespread metastases in February, 1946, just over two years after the direct irradiation. Post-mortem examination showed growth in the whole stomach, throughout the chest and abdomen, and in the brain. This was our first patient; he had a relatively small dose of irradiation and lived two years, most of which time he was free from any symptoms.

*Case 2.*—A man aged 67, with carcinoma of the pyloric antrum, had a laparotomy on Feb. 22, 1944, via the upper midline incision. The tumour was a hard irregular cylindrical mass encircling the pylorus and pyloric antrum, 6.5 cm. long and 5 cm. across. Glands in the lesser curve were taken for biopsy, and were reported on as early infiltration with carcinoma cells compatible with stomach primary carcinoma. The tumour and glands were irradiated with one tube, the maximal tumour dose being 1,000 r in 1.5 minutes. External irradiation was begun in nine days, but was stopped after a few days (275 r maximal tumour dose) owing to the development of a lung abscess. External irradiation was restarted six weeks later with a further 1,089 r. The total maximal tumour dose was 2,364 r in 56 days. Almost complete pyloric obstruction developed owing to fibrosis and contraction in tumour after irradiation. No improvement took place by May 30, 1944, so a gastro-jejunostomy was performed. The patient died of heart failure within a week. The second operation could have been avoided had a short-circuit been done at the first operation, though the patient was in poor condition then. The irradiation given was inadequate, but a larger dose was precluded by the patient's poor condition.

*Case 3.*—A man aged 60, with carcinoma of the greater curve, had a laparotomy on April 4, 1944, via the upper midline incision. The tumour was a large irregular stony-hard mass on the greater curve in the pyloric antrum measuring 13 cm. transversely, 7 cm. vertically, and 7.5 cm. antero-posteriorly, with an ulcer 7.5 cm. across facing into the lumen of the stomach. The tumour was attached to and invading the pancreas. There was a subserous spread on the surface of the tumour, and some was removed for biopsy. The report stated that there was a large spheroidal and round-celled adenocarcinoma of the stomach with well-marked mucoid change. No other spread

was found. The tumour was irradiated with one tube—maximal tumour dose, 1,000 r in 1.5 minutes. External irradiation was begun nine days later, amounting to a maximal tumour dose of 991 r in six days. The total maximal tumour dose was 1,991 r in 16 days. His pain disappeared within a few weeks of the direct irradiation, his general condition quickly improved, his appetite soon returned, and he returned to work as a stoker five months after direct irradiation, having gained 1½ stone (9.5 kg.) in weight. He was readmitted for further external irradiation on Nov. 23, 1944, as it was thought the initial dose was too small to cure the lesion. The second maximal tumour dose was 2,646 r in eight days. Systemic reaction was more severe and his recovery was much slower after this, but he continued to improve. He began vomiting at the end of March 1945, owing to obstruction at gastro-jejunostomy by contraction of the growth after treatment. He continued to vomit but refused further operation until the end of June, 1945, by which time his general condition was very poor. At this operation the duodenum proximal to the anastomosis was joined to the jejunum beyond, but he died a few days later from intestinal obstruction by a volvulus after the operation. Post-mortem examination showed growth in the stomach, mostly outside the treated area. He lived 15 months after the direct irradiation and might well have lived longer if he had allowed us to perform the second operation sooner.

*Case 4.*—A woman aged 54, with a leather-bottle stomach from pylorus to cardia, had a laparotomy on May 9, 1944, via the upper midline incision. The stomach was stony-hard from pylorus to cardia. Glands were found high in the lesser curve and below the pylorus. Biopsy of the gland showed undifferentiated glandular carcinoma. The tumour and gland were irradiated with difficulty with one tube, as it was impossible to get the whole lesion into the field of irradiation. The maximal tumour dose was 950 r in 1.6 minutes. External irradiation was begun nine days later, amounting to a maximal tumour dose of 2,310 r in 13 days. The total maximal tumour dose was 3,260 r in 23 days. She improved for a time and was quite free from pain. Her appetite did not improve, and she died at home four months later. A necropsy was not done.

*Case 5.*—A woman aged 57, with carcinoma of the abdominal oesophagus involving the cardia, had an angular abdomino-thoracic incision on May 16, 1944. The abdomen was explored and a small stony-hard pear-shaped tumour 5 cm. long by 2.5 cm. across was found encircling the abdominal oesophagus. There were no signs of spread. The incision continued into the thorax, but no spread was found there. Operation was not possible owing to the poor general condition. The tumour was irradiated with one tube, with a maximal tumour dose of 1,000 r in 4.26 minutes. External irradiation was begun in nine days, amounting to a maximal tumour dose of 2,541 r in 11 days. The total maximal tumour dose was 3,541 r in 20 days. Her general condition improved, and swallowing, which was previously limited to fluids, was very much better. She gained some weight. Further external irradiation to cover the length of the mediastinum and lesser omentum was begun on March 12, 1945. The maximal tumour dose was 2,046 r in four days. The systemic reaction was severe, but her general condition slowly improved. Swallowing became almost normal. Then she developed a pyrexia and died suddenly on Aug. 23, 1945—15 months after the direct irradiation. Necropsy showed death to be due to broncho-pneumonia and cirrhosis of the liver. There was no sign of viable cancer cells in the irradiated area, but some were found in the right lung base. This was the first gastric case for which we opened the thorax and abdomen together.

*Case 6.*—A woman aged 42, with carcinoma of the cardia, had an angular abdomino-thoracic incision and her abdomen explored on Nov. 14, 1944. A tumour about 6 cm. in diameter was found involving the cardia and abdominal oesophagus. Glands were found around the left gastric vessels; no other sign of spread was discovered. Biopsy of glands did not show any involvement with carcinoma cells. Incision continued into the thorax, but the general condition of the patient was too poor to allow direct irradiation or gastrectomy to be carried out, and the wound had to be closed hurriedly. Another attempt was made to expose the tumour for irradiation on Jan. 16, 1945, through the oblique abdomino-thoracic incision.

Great difficulty was experienced with adhesions, and again the operation had to be terminated rapidly before completion. The patient died some 36 hours later. Post-mortem examination confirmed the carcinoma encircling the cardia and lower abdominal oesophagus, causing complete obstruction. No other possible signs of spread were observed except the glands found at operation. Unfortunately this patient had been treated as a case of achalasia for some eight months, in spite of losing 1 stone (12.7 kg.) in weight and having gradually progressive symptoms.

**Case 7.**—A woman aged 46, with carcinoma of lesser curve, had a laparotomy on Nov. 21, 1944, via the upper midline incision. A saddle-shaped tumour 8 cm. transversely by 5 cm. vertically by 4 cm. thick was present on the lesser curve in the pyloric antrum and body. Hard glands were found along the lesser curve and below the pylorus and body of the pancreas. Biopsy of glands revealed infiltration by mucus-secreting carcinoma, showing little differentiation and increased fibrous stroma as in leather-bottle stomach. The tumour and glands were irradiated by two tubes, the maximal tumour dose being 1,528 r. in 2.4 minutes. The patient withstood operation and radiation very well, but suddenly collapsed and died just as the wound was being closed. Necropsy showed complete collapse of both lungs, for which no cause, either intra- or extrapulmonary, was found.

**Case 8.**—This patient, a woman aged 54, had a carcinoma of the lesser curve. Her abdomen was explored via an oblique abdomino-thoracic incision on March 23, 1945, and a saddle-shaped tumour measuring 8 cm. transversely by 4 cm. vertically by 4 cm. antero-posteriorly was found high on the lesser curve, extending a quarter-way round the lumen on each surface; it was stony-hard, nodular, with subserous spread. There were glands along the lesser curve. Biopsy showed moderately differentiated adenocarcinoma with much fibrous stroma invading the lymph gland. There was no other sign of spread. The incision was continued into the thorax. The tumour and glands were irradiated with two tubes, a maximal tumour dose of 1,542 r being given in three minutes. Her general condition improved, her appetite returned, and she gained in weight and lost all dyspepsia. Her stomach had contracted considerably some five months after irradiation, and she had to have frequent small meals. Later, she would not take much food because of the return of pain, and then vomiting began. Her abdomen was explored through a left paramedian incision on Sept. 28, 1945, when much clear fluid was found, with mild peritoneal spread of carcinoma. A palliative jejunostomy was performed, but she died within a week. Necropsy showed widespread involvement of the parietal and visceral peritoneum andomentum, with metastases. The stomach was greatly contracted and showed infiltration by growth from pylorus to cardia.

**Case 9.**—A man aged 68, with carcinoma of cardia, had the abdomen explored through an oblique abdomino-thoracic incision on Feb. 13, 1945. A tumour 6 cm. transversely by 4 cm. vertically by 3.5 cm. antero-posteriorly was found at the cardia. There were glands in the lesser curve and above the cardia, but no spread was observed elsewhere in the abdomen. Biopsy of the glands showed poorly differentiated adenocarcinoma invading the lymph-gland. The incision was continued into the thorax, but no spread was found there. The tumour and glands were irradiated with two tubes, the maximal tumour dose being 1,96 r in 1.8 minutes—smaller than intended because the lower tube became unstable and was turned off. The patient progressed very well for four days, when for no apparent reason spontaneous pneumothorax suddenly developed on the right side, causing rapid death from heart failure in spite of all attempts at resuscitation.

### Conclusions

To summarize our results, 15 out of 32 cases were treated by direct irradiation. In eight of these the disease appeared to be limited to an area that could be irradiated, and of this group one lived 24 months, two 15 months, one seven months, one four months, and one three months after treatment.

Although the series is small we feel sure that direct radiation at high intensity will prove to be a rational and

hopeful advance in the treatment of cancer of the stomach and other viscera. Whether the cancer is rendered inoperable by the poor general condition of the patient or by irremovable local spread, this method will often succeed where surgery alone must inevitably fail. Though wider exposure is needed than for surgery alone, with adequate precautions the whole procedure should not be so shock-producing as is wide surgical excision.

Exploratory operation is the only reliable way of deciding the correct form of treatment, and the hospital of the future will have a radiotherapy room adjoining the operating theatre to facilitate direct irradiation.

It is more reasonable to irradiate most what needs irradiating—i.e., the tumour and field of local spread—and not the overlying skin or intervening vital tissues.

Biopsy may not be practicable in all cases, as it is not altogether devoid of risk when there is no obvious glandular spread. But even biopsy is not always reliable, depending as it does on choice of the right piece of tissue, and being vitiated in some cases by variations in cellular differentiation in different parts of a tumour. Being able to see and feel the tumour should make the diagnosis more certain than when relying on external methods of examination alone, and biopsy will often increase that certainty.

Of course a method involving such extensive surgical procedures and such intensive irradiation must inevitably present new problems. Owing to difficulty in obtaining a sufficient number of suitable cases we have scarcely advanced beyond the "growing-pains." There are many modifications and improvements in technique we would like to try out. We hope that we have shown that our method is a reasonable and practicable possibility, and that eventually we may be able to improve on the present appallingly low cure rate of gastric cancer.

Unless and until we can achieve earlier diagnosis and bring a far greater number of operable cases to the gastric surgeon, there will remain a vast number of victims of this dreadful disease destined to die without even the hope of palliation or amelioration of their sufferings. Much more must be done for these patients, who greatly exceed numerically the relative few with operable lesions under the present conditions of diagnosis. Only too often our attitude is one of defeatism and despair towards these people, whose needs are often desperate. Even limited palliation for relatively large numbers might well balance the success achieved by spectacular and dangerous operations only possible for relatively few (Livingston and Pack, 1941).

## FIELD INVESTIGATION OF AN OUTBREAK OF DIPHTHERIA

BY

J. W. WEBB, M.B., B.S., D.P.H.

AND

N. MACFADYEN, M.B., D.P.H.

An outbreak of diphtheria limited to one house occurred at a boys' boarding-school. The history of the outbreak and the tracing of the source of infection may be of interest. The house contained 39 boys, a matron and her daughter (Mrs. T. and A.T.), a house-master, his wife, and four children. The domestic staff consisted of five persons for the boys and three for the family. The population at risk therefore comprised 55 persons, consisting of 11 adults, 40 adolescents, and 4 young children. The house was roughly divided into a private side and a school side, but two of the private-side maids, Y.S. and M.R., waited at table on the boys and family. These maids occupied a bedroom opposite to A.T., the matron's daughter.

### History of the Outbreak

A.T. attended a day school in London. During the half-term holiday the head mistress received a notification that a girl who had last attended school on Oct. 31 had developed diphtheria on Nov. 3. There was no direct contact between this girl and A.T., but on Nov. 12 A.T. developed diphtheria and was removed to the Isolation Hospital. This date occurred during the half-term holiday of the boys' boarding-school. All direct contacts were swabbed and found negative, but in spite of the negative swab Mrs. T. was isolated in her room for eight days as a near contact. The boys returned from the half-term holiday, spent at their homes, and as some of them had been in contact with A.T. previous to going away they were all swabbed. Five of the boys were found to be immune carriers of gravis type, so they were isolated at the school sanatorium. On Nov. 21, nine days later, one of the boys, the house-master's child, and the nursery governess all developed diphtheria. A child in the neighbouring town was also notified on Nov. 28, and two further cases occurred among the boys on Nov. 30.

Frequent throat and nose swabbing of all contacts of the cases was now carried out, and on Dec. 8 the matron and the butler were found to have positive throat swabs, and on these findings were admitted into the Isolation Hospital as carriers. As no K.L.B. were discovered at the Isolation Hospital after swabbing their throat and nose three times on alternate days, they were discharged on Dec. 14. On the 16th, however, the matron and butler were readmitted as they had again become positive. These two people were apparently transient carriers, as no positive organisms were detected on re-examination at the hospital.

The child in the town who developed diphtheria had been visited by one of the maids, Y.S., who was therefore subjected to repeated swabbing of the nose and throat, but every swab was negative. Subsequent inquiry, however, revealed the information that she had been suffering from sores on the scalp and limbs, which had been treated with a fair measure of success by the matron.

On Dec. 22 school holidays started. During the holiday Mrs. T., A.T. (now discharged from hospital), and the butler all had throat and nose swabs taken by their private doctors and were found negative. On Jan. 19, 1947, a few days before the school reassembled, the occupants of the private side returned to prepare the house. As an extra precaution they were swabbed again, and the matron and her daughter were found positive. They left the premises on Jan. 20, before the boys returned, and did not come back until March 1. On Feb. 12 a laundryman delivered a basket of clothes at the house and is said to have held a short conversation with one of the maids, M.R. This

man developed diphtheria on Feb. 16, twenty-eight days after the suspected carriers had left the house, and he suffered from a severe post-diphtheria paralysis. On Feb. 28 the night porter employed at the house also developed the disease and subsequently died of it. On March 1 the two maids, Y.S. and M., left the house and went to Hitchin. Before they left they had been in contact with a new nursery governess, who arrived Feb. 22. On March 17 this governess developed diphtheria.

Summarizing the results of the outbreak: in a community of 57 persons (55 originally and 2 newcomers) there were 11 cases of diphtheria, with one death, one case of post-diphtheria paralysis, and nine immune carriers. The outbreak continued in spite of the absence of the suspected carriers—the matron and her daughter.

### Continued Search for the Carrier

As the last three cases occurred after Mrs. T. and A.T. had left, suspicion fell on the butler, and on re-examining him a single colony of K.L.B. gravis was grown from the swabs taken on March 24, 26, and 27. Before the reports were received also had left the neighbourhood, and could not be traced until April 9, when three concurrent swabs were negative. It was felt that his low infectivity was not a sufficient explanation of the continuance of the disease, although possibly he was responsible for the case occurring on March 17. It was therefore decided to follow up the two housemaids who had gone to Hitchin. Owing to the extraordinary sequence of events at school the M.O.H. of Hitchin, co-author of this paper, had been informed of the arrival of Y.S. and M.R. at an inn in the district, and the following events occurred.

*March 3.*—Arrival of M.R. and Y.S. at the inn.

*March 10.*—A contact at the inn, S.B., developed a sore throat and was off work for a week.

*March 12.*—An out-worker at the inn developed diphtheria.

*March 21.*—A guest staying at the inn left for Brighton and was admitted into Brighton Isolation Hospital with diphtheria on March 24.

*March 24.*—V.B., S.B., Y.S., and M.R. attended a local dance.

*March 28.*—V.B. was admitted to hospital with diphtheria. Throat and nose swabs from Y.S. and M.R. were returned negative, but these two girls were admitted to the Isolation Hospital for further observation.

*March 31.*—A swab of S.B. was found positive and she was admitted to hospital for diphtheria. M.R. and Y.S. were discovered to have verminous heads, and in addition M.R. had scalp sores and an eczematous ear. (It is to be noted that whenever she had previously appeared for examination she had worn a head-scarf.)

*April 2.*—Swabs taken from M.R.'s external auditory meatus and scalp sores were all found to contain K.L.B., gravis type, and virulent. Y.S. was negative.

*April 4.*—Y.S. was discharged and left for her home. The M.O.H. was informed of her contact with a carrier.

### Possible Course of the Infection

There are three possible originators of this outbreak. In the first place, the girl at A.T.'s London school may have infected A.T. and through her the sores of the housemaids may have become contaminated with K.L.B. We think this is unlikely: twelve days is a long incubation period for diphtheria, and there is no evidence that the first girl already had the disease on the last day she attended school (Oct. 31), three days before her case was diagnosed. A.T. was isolated immediately diphtheria was suspected, and did not come into close contact with the maids before she was removed to hospital. Y.S. is the second possibility; and the chief point in suspecting her as the originator of the outbreak is that she was the only connecting-link between the school and the town who actually visited the house where the town case occurred. In addition, the matron dressed her sores, and she was in close contact with the butler, thus explaining the transference of the swabs taken from these two sources. St

waited on the boys at table, and the dates on which the cases fell among the boys are more suggestive of contact infection from one source than of infection from case to case. The last point applies equally well to M.R., and in addition she undoubtedly infected the laundryman. She did not, however, visit the child in the town. The Medical Officer of Health reports that by the time she was admitted to the Isolation Hospital at Hitchin her head was a mass of foul-smelling offensive sores, while Y.S. was comparatively clean. Taking the available evidence as a whole, we think M.R. was the originator and that she infected Y.S., whose skin was already in an unhealthy state. Y.S. took the infection to the town, but, possibly owing to the ministrations of the matron, by the time she reached Hitchin her sores were healing, and the infection was then carried on by M.R.

**Steps Taken to Prevent Spread.**—These were: (1) Careful and repeated swabbing of all members of the infected house and isolation of immune carriers; (2) isolation of the boys from the infected house; (3) protective injections (2,000 units of anti-diphtheria serum) and re-immunization of the boys and the domestic staff; (4) re-immunization of the rest of the school with 0.3 ml. A.P.T.

### Points of Interest

(a) The comparatively small number of cases and carriers in a closed community.—This is no doubt due to the relatively large proportion of protected persons within the community at risk. All the boys except two had had their primary immunization before joining the school. Of the two who had not, one contracted the disease. The other three boys who had the disease had been immunized in 1939, 1941, and 1940 respectively, thus suggesting that the protective power had lessened after five years and that a "boosting" dose was required. Nevertheless, it is reasonable to suppose that the primary immunization of these three boys had helped in combating the disease, as the two adult cases (the laundryman and porter) who had not been immunized were more severely infected. The immediate steps taken to heighten immunity in those not attacked were also effective.

(b) The difficulty of determining the significant carrier.—Much time was lost and two serious cases received their infection through the assumption that Mrs. T. and A.T. were the significant carriers. It was only an obstinate refusal to discard the school-town infection clue, even after negative swabs, that led to the M.O.H. at Hitchin being put on his guard and to the detection of the actual infectors.

(c) That a number of cases of pharyngeal diphtheria occurred from a skin infection of virulent gravis diphtheria.—Although not unknown, this is an unusual occurrence and should lead to a careful scrutiny for skin lesions in an unexplained prolongation of an outbreak.

The spring number of the *American OSE Review* is particularly interesting for a number of articles by Jewish doctors on their experiences in the ghettos and concentration camps established by the Germans. Dr. E. Herman gives an account of a typhus epidemic in 1941-2 in the Warsaw ghetto, where over half a million people were crowded together. "Liquidation" of the ghetto followed in 1943, being "preceded by a tour of S.S. men and Gestapo with monocles in their eyes in shiny limousines." There were about 80,000 cases in the epidemic; he tabulates the neurological syndromes found. Conditions in the Vilna ghetto were little less deplorable, and Dr. Dworzecki mentions that about 75% of the women ceased to menstruate for a varying period of time soon after being herded into it. The camp commandant ordered several women with severe scabies to be shot. Dr. Rosenblum briefly describes the destruction of the Jewish community in Warsaw by shooting, gas, and burning, and the plight of children left to wander in the ruins and forests.

## PARTIAL HEPATECTOMY AND RIGHT HEMICOLECTOMY FOR CARCINOMA OF THE HEPATIC FLEXURE

BY

RONALD W. RAVEN, O.B.E., F.R.C.S.

*Surgeon to the Royal Cancer Hospital (Free); Surgeon to the Gordon Hospital for Diseases of Rectum and Colon*

The object of this paper is to call attention to the feasibility of carrying out an operation for the removal of a carcinoma of the hepatic flexure of the colon which involves the right lobe of the liver by direct extension. Coincidental partial hepatectomy at the time of gastric resection for carcinoma involving the liver by direct extension from the stomach has been performed by Wangenstein (1943, 1945). It is of interest also to remember that in 1923 Grey Turner stated: "Direct extension of malignant disease from the stomach or colon may render removal of a portion of the liver necessary, and I think this will become one of the most frequent indications, especially as it usually only involves the removal of a slice or wedge from the edge of the organ. In cases of this kind such an extension to the liver need not in itself be a bar to successful operation if the extension of the growth in other directions rendered its removal profitable." Some six years ago I performed a right hemicolectomy for a carcinoma of the hepatic flexure which invaded the right lobe of the liver, and it was necessary to remove a slice of liver with the growth; this patient remains well without recurrence at the present time, proving that the end-result of such an operation is most satisfactory. Recently, however, a much more formidable problem presented itself, and it was necessary to remove a large portion of the right lobe of the liver, including the gall-bladder, for a massive carcinoma involving the liver and hepatic flexure of the colon. Two months previously a surgeon who performed an ileo-transverse-colostomy as a palliative measure considered this growth to be inoperable on account of the extension to the liver. The clinical details concerning this patient are embodied in the case record given below. Since an operation for resection of a large lesion of the right lobe of the liver is a rare surgical procedure the technical details are described.

### Case Record

A man aged 38 developed pain in the right lower abdomen when in India a year ago. It was sharp in character and was accompanied by diarrhoea. This attack subsided and he was able to continue his work. Several weeks later the diarrhoea recurred with four stools a day. He still experienced pain in the right lower abdomen. His appetite was good and he felt fairly well. Seven months ago the abdominal pain became continuous; he lost his appetite, and noticed that the bowels had become constipated. He gradually lost strength, and on examination a lump was found in the right iliac fossa. Three months before we saw him he reached this country and was admitted to another hospital. A hard mass was noted in the right hypochondrium, blood was present in the stools, and *Entamoeba histolytica* was demonstrated. An x-ray examination after a barium enema showed a large filling defect in the transverse colon. He was given a course of emetine therapy to exclude an amoeboma, but this treatment had no appreciable effect. An exploratory laparotomy was then performed after preliminary blood transfusion, and the mass appeared to be a large scirrhous carcinoma of the transverse colon just medial to the hepatic flexure and invading the gall-bladder and liver, to which it was densely adherent, but no secondary deposits were found. The growth was considered to be inoperable and an

ileo-transverse-colostomy was performed. The patient made a good recovery from the operation, the colicky abdominal pain subsided, the stools were normal, and his appetite improved.

Later his condition began to deteriorate, with the development of severe secondary anaemia, and in spite of three blood transfusions of 1 pint (568 ml.) each, the red blood corpuscles fell to 2,400,000 per c.mm. and the haemoglobin to 35%. There was severe pain in the region of the tumour and he was transferred to the Royal Cancer Hospital. On examination the patient looked ill and pale, and had obviously lost much weight. There was a large mass in the right half of the abdomen extending from the right hypochondrium to the upper limit of the right iliac fossa; it was extremely tender and appeared somewhat fixed. Sigmoidoscopy revealed no abnormality; a smear from the bowel showed no cysts or amoebae. There was marked secondary anaemia; red blood corpuscles numbered 1,900,000 per c.mm., and the haemoglobin was 28%. The plasma proteins were normal; plasma ascorbic acid was subnormal. A fractional test meal showed no abnormality. Radiological examination of the colon after a barium enema revealed a large irregular filling defect at the hepatic flexure extending 2 in. (5 cm.) into the transverse colon and 4 in. (10 cm.) into the caecum. This had the appearance of a carcinoma. The patient was given three blood transfusions of 3 pints (1.7 litres), 1½ pints (0.85 litres), and 5 pints (2.84 litres). The last massive transfusion was given because of a rapid deterioration in his general condition, probably due to haemorrhage occurring from the growth into the colon. It was decided—and the patient and his wife wished it—to perform an exploratory laparotomy to determine whether the mass could be removed. This operation was performed on Feb. 12, 1947, and a large mass was found involving the hepatic flexure of the colon and the right lobe of the liver. No metastases were found elsewhere in the liver or in the rest of the abdomen, and the ileo-transverse-colostomy was perfectly satisfactory. It was decided to perform a right partial hepatectomy and right hemicolectomy. The patient has made a good recovery. Microscopical examination of the tumour showed a highly cellular adenocarcinoma.

### Technique of Partial Hepatectomy

After visual inspection and careful palpation of the right lobe of the liver the line of section is determined so that the excision is performed through normal tissue wide of the growth. The right lateral ligament of the liver is divided and the organ is delivered as far as possible into the wound by manual traction. The incision begins on the lateral aspect of the right lobe and the diathermy knife is used. It is essential to divide small areas of the liver at a time so that haemorrhage is completely controlled. This is effected by digital pressure on the liver tissue with gauze and by the insertion of mattress sutures of catgut, using special liver needles. It is pointed out that owing to the thickness of the right lobe of the liver it is impossible to insert through-and-through sutures from the antero-superior to the postero-inferior surfaces, and each suture therefore takes in about half the thickness of the organ. When the middle of the lobe is reached an incision is begun on the antero-internal aspect, passing posteriorly to the gall-bladder. The intrahepatic branches of the right hepatic artery are secured by the application of pressure forceps and are ligated. It is useless to employ pressure forceps to control haemorrhage from hepatic tissue apart from these well-defined vessels. This incision progresses to the middle of the lobe until it meets its fellow from the opposite side. The cystic duct and cystic artery are then ligated in continuity and divided, thus liberating the excised portion of the right hepatic lobe. The raw area of the liver is inspected, and bleeding points are touched with the diathermy coagulating knife; thus all haemorrhage is controlled. This area is covered with several layers of gauze, which are removed at the end of forty-eight hours. Alternatively it can be shut off by means of the great omentum, but it is necessary to drain

the area because of the leakage of bile for several days the post-operative phase. It is possible that the use of fibrin foam may in future prove of value in dealing with haemorrhage from the cut surface of the liver.

### Pre- and Post-operative Treatment

Before an operation of this magnitude is performed investigations are made as to the patient's general fitness and any abnormalities are rectified whenever possible. Special attention is given to the cardiovascular, respiratory and urinary systems. The blood is examined to determine the degree of secondary anaemia and whether there is protein deficiency. A severe degree of secondary anaemia may be present, and a number of pints of blood are required to bring the haemoglobin content up to a level of at least 70%. The blood ascorbic acid is estimated, and the patient is given this substance in doses of 100 mg. twice daily, together with thiamine and riboflavin in doses of 3 mg. thrice daily. A high-protein and high-carbohydrate diet is given, with plenty of fluid.

Blood transfusion is started during the operation, and this continues into the post-operative phase, the amount transfused depending on the patient's condition. Intravenous fluids are given for at least during the initial forty-eight hours until intestinal peristalsis returns, when the patient can begin to take small quantities of fluid by mouth. He requires a minimum of 3,000 ml. of fluid in twenty-four hours, composed of 400 ml. of plasma and the rest of glucose-saline. After partial hepatectomy the patient is apt to become dehydrated and to develop secondary anaemia; a blood transfusion may be required to rectify this condition. Casein hydrolysates are given in order to increase the protein intake, and in spite of the daily dose of ascorbic acid the blood values of this substance may be subnormal. The availability of superficial veins for transfusion purposes may become distinctly limited, and in this patient it was necessary to use the right external jugular vein, which was quite satisfactory. When the right area of the liver is drained anteriorly through the right paramedian incision, and not through a stab incision in the right loin, it is advantageous to employ postural drainage by turning the patient into the ventral position every twenty minutes every two hours by day. Skilled nursing and meticulous attention to all details in the management of the patient are essential, and the rehabilitation programme must be carried out very gradually whenever the liver has been subjected to trauma. Jaundice may develop during convalescence in patients who have had wounds of the liver, and they must be kept under careful observation for a long time after discharge from hospital.

### Summary

Attention is directed to the operation of partial hepatectomy combined with right hemicolectomy for carcinoma of the hepatic flexure of the colon infiltrating the right lobe of the liver. The technique of partial right hepatectomy is described and the pre- and post-operative management is given. The clinical history is cited of a patient for whom this operation was performed successfully, and another patient is cited who is some six years after resection of the anterior aspect of the right lobe of the liver combined with right hemicolectomy for carcinoma of the hepatic flexure of the colon.

## HERNIA OF THE DIAPHRAGM AS A -COMPLICATION OF LABOUR

BY

RYAN C. MURLESS, M.B., F.R.C.S., M.R.C.O.G.

*Assistant Visiting Gynaecologist and Obstetrician,  
King Edward VIII Hospital, Durban*

Diaphragmatic hernia in the parturient woman is probably not excessively rare. The lack of references to such cases in the medical literature therefore seems remarkable, especially as regards prognosis, of which I can find no mention. Even Browne's (1944) comprehensive book does not include this complication of pregnancy. A practitioner faced with a radiograph showing a large hernia through the diaphragm in a woman nearing term cannot be blamed if he feels somewhat apprehensive as regards labour, with the additional strain and pressure which will accompany the pains, and he may be tempted to perform a quite unnecessary caesarean section. I have had two cases of large diaphragmatic hernia and one of eventration of the diaphragm under my care during their confinements, and I feel that the publication of a brief note may prove helpful. These cases were seen before September, 1939, and the clinical notes are scanty and incomplete, as the original hospital case sheets cannot be traced.

### Case Reports

**Case 1.**—This patient, aged 21, had had one previous confinement without complications. The weight of the child was not recorded. She was well till the thirty-sixth week, when dyspnoea on the slightest exertion and occasional vomiting started. A radiograph of the chest demonstrated a large diaphragmatic hernia on the right side, with the greater part of the stomach bulging into the thorax through the diaphragm. There was no obstetrical abnormality and the head was deeply engaged. It was decided to induce labour prematurely, and surgical induction by puncture of the membranes was performed at the thirty-eighth week. Pains started soon afterwards. Morphine, 1/6 gr. (11 mg.), hyoscine, 1/150 gr. (0.43 mg.), and paraldehyde, 6 dr. (21 ml.), in olive oil were given per rectum during the course of labour. A child weighing 6 lb. 4 oz. (2.9 kg.) was delivered naturally twenty-two hours after rupture of the membranes. Slight dyspnoea was evident at times during the second-stage pains, but was not severe enough to cause anxiety or require treatment. There was no cyanosis. Immediately after delivery vomiting was troublesome and continued for four days. Attacks recurred during the remainder of the puerperium unless meals were kept dry and small. Eventual recovery was satisfactory and further symptoms are not recorded. Surgical treatment for the hernia was not advised.

**Case 2.**—This patient, aged 36, had had two previous confinements, which according to her statement were uncomplicated. A radiograph of the chest was taken late in pregnancy after complaints of shortness of breath. This revealed a very large diaphragmatic hernia on the right side, reducing the thoracic space on that side to what appeared to be an alarming degree. The patient was admitted to hospital and put to rest, when labour started spontaneously. The first stage was quick and caused no abnormal symptoms. Second-stage pains, however, caused considerable distress, with dyspnoea, and at times slight cyanosis. Oxygen was administered during the pains throughout the second stage and gave great relief. There was some delay with the head on the perineum, and the patient was delivered easily by a low forceps operation under light chloroform, ether, and oxygen anaesthesia. Recovery was uneventful.

**Case 3.**—This patient, aged 25, had had one previous confinement which resulted in a stillborn child weighing 9 lb. (4.1 kg.) being delivered by forceps. During the present

pregnancy she had attacks of epigastric pain and shortness of breath. Examination of the chest revealed dullness at the left base, with weak breath sounds and absence of vocal resonance. The apex beat was 1½ in. (3.8 cm.) to the left of the sternum. A left-sided pleural effusion was suspected, but a radiograph revealed a marked degree of eventration of the diaphragm, which was confirmed by screening. Labour started naturally at term and lasted five hours. There were no signs of distress during the second stage, and a child weighing 7 lb. 13 oz. (3.5 kg.) was delivered. Partial separation of the placenta and a moderate post-partum haemorrhage complicated the third stage. Eventual recovery was satisfactory.

### Discussion

Diaphragmatic hernia is usually classified as congenital or acquired and true or false. A so-called false hernia has no sac. Eventration of the diaphragm and thoracic stomach, with a short oesophagus, may produce the same symptoms as a true hernia by diminishing the space available for lung expansion and oxygenation of the blood. Of the true hernia the congenital type is rare, and is stated by Richardson (1929) to occur more often on the left side. All authorities agree that the acquired type is nearly always found on the right side at the site of the oesophageal hiatus, and it is probable that Cases 1 and 2, described above, were of this variety. Such hernias are thought to be due to congenital weakness of the muscular ring of the oesophageal hiatus, allowing the sac to bulge into the right pleural cavity alongside this structure. It seems that small hernias of this description are not uncommon. Rigler and Eneboe (1935) were able to demonstrate forty-four cases of hernia in 4,200 radiological examinations, and they stated that the condition is commoner in the female in the ratio of 15 to 4. Harrington (1935) stated that routine examinations during laparotomy show that in 50% of persons no para-oesophageal opening can be felt, but in 50% two or three fingers are admitted. He regards an opening admitting up to two fingers as within normal limits. Increased intra-abdominal pressure seems undoubtedly a factor in producing or increasing the size of these hernias, and the stomach may slip in and out of the sac according to the degree of pressure and gastric tension. Ude and Rigler (1929) have observed such cases in women following multiple pregnancies, large ovarian cyst, large myoma, and ascites with malignancy. Rigler and Eneboe have also shown that small para-oesophageal hernias are by no means uncommon in late pregnancy. In 195 radiological examinations in the third trimester of pregnancy they demonstrated hernias in 12.8%—in 18.1% of the multiparas and 5.1% of the primiparas. In routine gastro-intestinal examinations they found such hernias in only 1%. Therefore it seems reasonable to presume that some degree of hiatus hernia is not uncommon in late pregnancy, especially in multiparas or in women in whom there has been a previous increase of intra-abdominal pressure from some other cause. The number of these hernias which reach proportions large enough to cause symptoms in late pregnancy or labour must be small, as it has already been pointed out that there is little mention of such cases in the medical literature. Large hernias which do not cause symptoms are, however, likely to go unrecorded unless discovered accidentally, as exact diagnosis is not possible without chest radiography. But if, as according to Rigler and Eneboe (1935), 12.8% of women have some degree of hernia in late pregnancy it seems likely that a small proportion of these may enlarge with repeated pregnancies; or, again, it is possible that any large hernia encountered is originally of congenital origin.

**Symptoms.**—The common symptoms caused by hernia through the diaphragm associated with pregnancy are

gastric upsets—that is, nausea or vomiting—and dyspnoea. If such symptoms occur they usually start late in pregnancy, after the thirty-fourth week. The three cases described all suffered from dyspnoea during late pregnancy, and in Cases 1 and 2 it caused some distress during the second stage of labour. In Case 1 there was vomiting in late pregnancy, which was especially aggravated after delivery and continued to be troublesome during the puerperium, probably owing to some alteration of the position and tension of the stomach after the uterus had emptied.

**Treatment.**—During late pregnancy the patient must rest more than usual, and if dyspnoea is not relieved should be confined to bed. Vomiting can usually be relieved by attention to the diet. Small and frequent meals of soft food or fluids may be necessary. Postural treatment may be useful, the patient herself usually finding out which position suits her best. Laxatives should be given to ensure regular bowel action. In cases with severe encroachment on the thoracic cavity induction of premature labour must be considered. A long second stage is not desirable, as the dyspnoea may increase with the pains and the patient become distressed. If, therefore, there is any reason from the history or clinical findings to suspect that labour may be prolonged, induction at the thirty-eighth week is probably the wisest course. A medical induction may be tried, and if this fails the membranes should be ruptured. If disproportion or other obstetrical complications are present caesarean section will of course have to be considered. During labour the usual sedatives should be given in the first stage. Oxygen may be necessary during the second stage and is essential if the patient becomes at all cyanosed. It should be given during the pains, and affords great relief. Low forceps delivery and episiotomy are indicated should there be the least delay on the perineum. Cyclopropane or local anaesthesia should be used.

In the puerperium careful dieting may be necessary if vomiting is troublesome as in Case 1. Vomiting usually ceases within a week as the stomach settles to its new position and gastric tension becomes adjusted.

The question of after-treatment of these large hernias cannot be fully considered here. In the majority of cases all symptoms disappear after delivery. Most authorities are of the opinion that surgical treatment is not indicated in cases of large hernia unless the sac is known to contain small gut and is therefore liable to strangulation. Morrison (see Richardson, 1929) believes that relatively few cases require operation. Treatment on medical lines should be continued if any symptoms persist.

**Prognosis.**—In all three cases described there was a severe degree of encroachment on the thoracic space—in two by true diaphragmatic hernia and in one by eventration of the diaphragm. The main object of this publication is to emphasize that labour may be allowed to proceed with safety under such conditions and that catastrophic effects do not occur. Whether the hernial hiatus is further enlarged as a result of labour is a matter for conjecture. Unfortunately these cases were not re-examined radiologically after the puerperium. Rigler and Eneboe, however, re-examined twenty-five cases after the puerperium in which small and moderate degrees of para-oesophageal hernia had been present in late pregnancy. They found that in only three of these cases could a hernia still be demonstrated radiologically. It seems, therefore, that though further stretching of the hiatus is probable during pregnancy and labour the hernia will retrogress as soon as the abdominal tumour is removed, and in many cases with only small and moderated degrees the condition will revert to normal. This conclusion is supported by the cessation of symptoms in nearly all cases after the puerperium.

## A NEW TREATMENT OF RHEUMATOID ARTHRITIS

BY

IMRE BARSÍ, M.D.

Formerly Head Physician of the Rheumatism Sanatorium  
Margareten Island, Budapest

It is always difficult to prove the value of a new therapy especially when it concerns a disease which, like rheumatoid (atrophic) arthritis, to a great extent improves spontaneously, without any treatment. The *Primer on Arthritis* issued by the Committee of the American Rheumatism Association in 1942, contains the following about rheumatoid arthritis: "Few accurate statistics on the natural course of the disease are available, but in general it may be said that fewer than one-fourth of the patients 'recover,' or half 'improve' or the disease becomes 'quiescent,' and remaining one-fourth become progressively worse. It is particularly important that these facts should be borne in mind when one is assessing the value of any therapeutic regimen."

According to literary data, the results of the gold, heteroprotein, and vaccine therapies are almost the same—that 65–75% are cured or improved and some 25–35% remain unchanged. If we compare these data with the statement quoted above, we get the amazing fact that nearly as many recover without any treatment as with treatment. The apparent paradox indicates that either all our therapies are worthless or statistics are unsuitable for assessing therapeutic effects.

Hitherto we have tested the value of a therapy by determining what percentage of a given number of cases we cured or improved. This is, however, a misleading procedure, because the number included those which healed spontaneously. We can assess the value of a new treatment only by determining how many cases it cured or improved out of the "one-fourth" which did not improve either spontaneously or by the usual therapies. Should such a case improve or recover—and especially if the improvement is quick and lasting—then we can be convinced that the change is not spontaneous but a result of the new therapy. To an experienced physician it cannot be difficult to select from his patients the cases suitable for testing, and I am sure that in the cases reported below there is no doubt about their belonging to this category. I thought it necessary to raise these considerations of method before proposing a new treatment for rheumatoid arthritis.

A young woman suffering for three years from rheumatoid arthritis became pregnant. In the third month of her pregnancy she recovered unexpectedly, though until then her disease had seemed incurable. Later on I saw another similar case: the patient twice became pregnant, and in both instances her illness stopped; but after childbirth it recurred. Similar cases have been observed by others although naturally not in great numbers, because few women in such an invalid condition become pregnant. P. S. Hench (1938) collected from American medical literature the reports on the pregnancy of women suffering from rheumatoid arthritis. He found, from 1864 onward

en authors giving accounts of thirty-seven cases of pregnancy among twenty women. These twenty women improved to an astonishing extent during thirty-four of their pregnancies. The improvement, however, ceased some time after their delivery (9.4 months afterwards on an average).

### The Method

I presumed as an explanation of this recurrence that pregnancy produces an unknown material which causes the improvement. Further, I assumed that this hypothetical material circulates in the blood of pregnant women and can be transfused and utilized elsewhere. On the basis of these conjectures I transfused the blood of pregnant women into persons suffering from rheumatoid arthritis. In each case I gave 300 ml. of citrated blood. I repeated this several times, according to the symptoms of improvement. To demonstrate my results—for the reasons outlined above—I did not choose the statistical method. Statistically, I got with this treatment the same result as with the other therapies—that is, of 28 cases 64% recovered or improved and 36% remained unchanged. But to meet what I said in the introduction to this account I selected those seemingly hopeless cases in which scientific treatment had so far yielded no result—cases, therefore, which undoubtedly belonged to the "one-fourth" who became "progressively worse."

I would call attention especially to two facts. First, the speed with which the improvement took place. Compared with the months or years needed to effect an improvement with gold therapy—which seems to be the most efficacious method at present—the improvement in our cases came with dramatic suddenness. Secondly, the lasting effects of the improvements. Patients Nos. 2, 3, and 6 remained healthy up to the time of writing (1946), and have not relapsed. They feel the changes in weather conditions, and during menstruation their joints are sometimes sensitive, but a real relapse has not occurred. Patient No. 4 committed suicide in 1944, for fear of the persecutions. Patient No. 1 was killed in 1944 by the Nazis. Until their deaths both had been free from symptoms.

Not all cases react equally well to these transfusions. We are discussing a disease of which the exact pathogenesis is unknown to us; we do not even know whether it is a homogeneous illness or a group of substantially different diseases showing only similar clinical features. So long as we are unable to differentiate the subspecies and determine in advance which case will improve by this method, we have to be satisfied with the fact that there are some cases of rheumatoid arthritis which can be promptly and permanently cured by the unknown material circulating in the blood of pregnant women.

### Case Reports

**Case 1.**—A married woman aged 41 first had the disease in 1938, without fever, and within two months all her joints were affected. Mitral insufficiency was present. The sedimentation rate was 50 mm. Except for the hips, all joints were swollen and painful. Her moving and walking capacity was limited. The simplest actions—dressing, washing, getting up—could not be performed without help. The tonsils and dental abscesses were removed. No treatment brought any improvement. She was given 300 ml. of blood from a pregnant woman on Jan. 1, 1941. Chills and a temperature of 100.8° F. (38.2° C.) followed. Next day the improvement was surprising. She regained her power to move and the pains ceased almost completely. She got up, dressed, put on her shoes by herself—actions which she had been unable to do for months—and in her exhilaration began to knead bread, although the day before she had been unable even to button her dress. The improvement achieved on the first day was lasting, and slowly increased. Several trans-

fusions were given during the following years. All improvements proved to be lasting. She was able to walk long distances, to work, and to run her house. During menstruation her joints were somewhat sensitive. Until her death in 1944 there was no relapse.

**Case 2.**—A 25-year-old woman first had arthritis in 1933. All her joints were progressively affected, and fever was present. In 1939 she had pneumonia and myocarditis. Before the transfusion she was for four months under hospital treatment for polyarthritis. Except for her hips, all her joints were affected and she was completely disabled. The sedimentation rate was 50 mm. The first transfusion of 300 ml. of blood from a pregnant woman was given on Feb. 17, 1941. Chills and a temperature of 103° F. (39.4° C.) followed, but next day there was improvement, especially in the joints of the upper limbs. The pains diminished substantially, and the joints became free. A little later the improvement reached the joints of the lower limbs, and she steadily improved. Several transfusions were given, but after the first she was completely healed, was free of pain, and was able to work.

**Case 3.**—A 32-year-old dressmaker had polyarthritis gravis. Her illness began in 1931, in her knees and wrists, with fever. During the next ten years the disease spread to all her joints, mostly with feverish attacks. Since 1939 the disease had grown rapidly worse. The feverish periods were more frequent and longer. In September, 1939, she had myocarditis. Since 1939 she had been in hospital five times and when I first saw her she had been in hospital for eight months. She was completely crippled, could not walk, move, or work. In the last months she could not even leave her bed. The sedimentation rate was 50 mm. On March 29, 1941, a transfusion of 300 ml. of blood from a pregnant woman was given and she felt better the same day. The improvement increased during the next days. The pains diminished, the joints became freer, and on the fifth day she walked round the ward for the first time in five months. We repeated the transfusion several times. The improvement continued. She is practically cured, and is able to earn her living again. Up to the time of writing (1946) she has had no relapse.

**Case 4.**—A man aged 66 had been ill for four years, with feverish attacks. Treatment had not helped him, and the polyarthritis progressed irresistibly. He suffered severe pain and was unable to get up or to turn over in bed by himself. His gait was very clumsy and his appearance was Parkinson-like. He had to be washed and dressed. For three months he had been under hospital treatment. The sedimentation rate was 58 mm. On April 9, 1941, a transfusion of 300 ml. of blood from a pregnant woman was given. The upper limbs became more active on the next day, his bearing straightened, and his gait was easier. His condition improved rapidly and progressively. He felt stronger and healthier in general, and left hospital substantially improved. I saw him two months later, when he was completely cured.

**Case 5.**—A woman aged 48 had had polyarthritis for ten years. Except for the hips and knees, which were painful, all her joints were swollen and their active or reflex movements limited. The sedimentation rate was 25 mm. A transfusion of 300 ml. of blood from a pregnant woman was given on June 2, 1941, and fever followed. The first signs of improvement were observed on the sixth day. She gradually improved, the pains decreased, the swellings were reduced, and movements and walking were better. The transfusion was repeated, and she left the hospital in a painless, active state.

**Case 6.**—A woman aged 29 had ischialgia in 1937. Polyarthritis began in April, 1940, and gradually affected all her joints, but there was no fever. When I first saw her all her joints were more or less affected, deformed, swollen, and painful. She could walk only with great difficulty and was unable to work. The sedimentation rate was 40 mm. On July 8, 1941, she received 300 ml. of blood from a pregnant woman. Improvement began on the sixth day. After several transfusions the pains ceased. She has some sensitiveness to weather, but can move and work. Up to the time of writing (1946) she has had no relapse.

## Medical Memoranda

### Tuberculosis of the Adenoids

In 1945 fifteen cases of tuberculous cervical adenitis were treated at the country branch of the Hospital for Sick Children. Shortly after admission the tonsils and adenoids were removed and examined microscopically. The incidence of tuberculous infection of the tonsils was about 70%, as might be expected from a study of the literature, but it was surprising to find that in this short series three cases showed infection of the adenoids. They are recorded because tuberculosis of the adenoids is rarely mentioned. In 1924 Crowe and MacCready, in an analysis of the pathology of tonsils and adenoids removed at the Johns Hopkins Hospital, noted that tuberculous lesions were present in 2.5% of 1,000 cases of adenoidectomy. In these cases there was no clinical evidence of tuberculosis. No other record could be found of the incidence of tuberculosis of the adenoids in children. One case in an adult was described by Pegler in 1911.

#### CASE REPORTS

**Case 1.**—A male child aged 15 months was admitted to hospital on Aug. 10, 1945, with many enlarged glands in both sides of the neck and a discharging sinus in the left side. He had had cervical adenitis since the age of 3 months. His general condition was fairly good, and his weight and height were normal. The tonsils and adenoids were removed on Sept. 25, 1945. Section showed tubercles with giant cells in both tonsils and in the adenoids. At no time was there any clinical or x-ray evidence of tuberculosis of the chest or elsewhere.

**Case 2.**—A female child aged 11 months was admitted to hospital on April 18, 1945, with bilateral enlarged cervical glands and a fluctuant abscess below the left mandible. The glands had been enlarging for about a month, and although the child was a little underweight she was plump and looked fairly well. The abscess was immediately incised and expressed. There was a little further glandular enlargement and loss of weight during the next two to three weeks; then she began to improve, and on May 17 was fit for removal of the tonsils and adenoids. This was done, and a second abscess was expressed. Section showed tuberculosis of the adenoids but not of the tonsils. There was no clinical or x-ray evidence of tuberculosis elsewhere.

**Case 3.**—A male child aged 13 months was admitted to hospital for cervical adenitis in February, 1946. He had a discharging abscess on the right side; this was expressed and the tonsils and adenoids were removed on May 4, 1946. He looked well and was a little above the average weight for his age. Section showed evidence of tuberculosis of the right tonsil and of the adenoids. There was no clinical or x-ray evidence of tuberculosis elsewhere.

#### COMMENT

In each of these cases there was gross cervical adenitis in a child under 2 years of age, and the tuberculin patch test was positive. There was no evidence of tuberculosis of the chest or elsewhere, the weight was about the average or above the normal for the age, and the general health appeared to be good. Clinically there was very little enlargement of the tonsils and adenoids in the first two cases and no inflammation. In the third case there was some enlargement and inflammation of the tonsils during the early part of the illness. No information was obtained as to the origin of the infection in these cases. In none of them was the condition of the tonsils and adenoids such that their removal would have been advised on ordinary clinical grounds. It is probable that investigation of a larger series would reveal infection of these tissues to be more common than is generally supposed.

Treatment consisted in removal of the tonsils and adenoids, expression of glands in which abscess formation had occurred, and general care in the hospital's country branch. These cases are interesting in comparison with cases of streptococcal cervical adenitis. Here the child is pallid and debilitated, and often acutely ill with enlarged red tonsils and nasal obstruction. In the tuberculous infection many glands may be grossly enlarged, but the child is relatively well and the tonsils and adenoids are small and pale.

Macroscopically the tonsils and adenoids were small and of a soft, firm consistency. Sections showed giant-cell systems and areas of necrosis typical of tuberculosis. In these cases there

was no difficulty in demonstrating the pathology in sections taken from any part of the tissue. No special technique was used.

Acknowledgment is due to Mr. Denis Brown, F.R.C.S., for permission to publish these cases, and to Drs. Richardson and Bodian for preparing the sections.

### Mental Disturbance as the Leading Symptom in Typhoid Fever

The following case of typhoid fever is worth recording because of the prominence of mental symptoms and the indefiniteness of the pyrexial illness in the early stages. It also illustrates the difficulty experienced during the war in interpreting symptoms of psychoses in the Middle East where toxic confusional states occurred far more often than at home. Pyrexia of unknown origin was common and was as likely to occur in a patient in a psychiatric hospital as elsewhere.

#### CASE REPORT

An Army chaplain aged 36 was admitted because of increasing mental disturbance over the past six days. He was by this time restless and agitated, banging his head against the wall and crying out that all was lost. No contact could be made with him other than that he begged to be placed before a firing squad. His voices were accusing him of having turned from God, and were threatening him with eternal torment such as his wife and child supposedly in the next room, were suffering at the hands of the devil in being boiled in oil and yet unable to die. He had been pyrexial for several days, so a full investigation into this was made after examination by the medical specialist and under his guidance.

Clinically nothing whatsoever pointed positively to typhoid in the last few days of the illness. Blood investigations revealed nothing abnormal, with the exception that after two subcultures a growth of what was identified as *Bact. typhosum* was found. This identification was made on what was estimated as the thirteenth day of the pyrexia. In the meantime the patient's condition deteriorated rapidly, and he died the following day. A post-mortem examination showed typical typhoid changes throughout, though intestinal perforation had not occurred.

During the course of the illness the mental disorder had given considerable concern. The acute symptoms had been of gradual onset and at first appeared to be quite unconnected with an incidental pyrexia. The patient became depressed, stated that he did not feel well, and spent hours looking at family photographs. He had been under a psychiatrist for two months on account of emotional instability, undue activity, and vociferation about his work. He had admitted a previous depressive breakdown; but now he had become disorientated, and lived in a state of continuing torment in what he considered to be gaol. He was intensely suicidal and had to be restrained. From the first he was resistant and uncooperative, and was continually whispering hoarsely that he was going through hell. He maintained that he had no physical illness. The same delusions of persecution persisted throughout, accompanied by extreme agitation, until he became comatose through exhaustion the day before he died.

#### COMMENT

Here the depressed form of acute confusional psychosis occurred in a febrile illness which proved to be a fatal case of toxæmic typhoid fever. Depression began at or just before the onset of pyrexia in a man of known cyclothymic constitution and progressed, with the development of acute suicidal tendencies, as the pyrexia continued, later being absorbed in a confusional setting of disorientation, imperception, and acute hallucinosis. The persistence of relatively fixed delusions suggested the precipitation of a depressive psychosis. This case illustrates the difficulty of diagnosing the depressed form of confusional psychosis and shows well the resemblance between this disorder and the depressive phase of manic-depressive psychosis, and occasionally the depressed form of katatonic

I wish to thank Col. O. J. O'Hanlon, late R.A.M.C., for permission to describe this case.

## Reviews

### WORCESTER ROYAL INFIRMARY

*A History of the Worcester Royal Infirmary.* By William Henry McMenemey, M.A. (Pp. 356; illustrated. 21s.) London: Press Alliances, Ltd. 1947.

This handsome book has evidently been a labour of love for its author, and we cordially congratulate him on the result. It is the history not only of a notable hospital but of many aspects of civic life in Worcester during the past two hundred years. The hospital is one of the oldest provincial voluntary hospitals, and it owes its birth mainly to the vigorous personality of Bishop Isaac Maddox, a distinguished churchman who, fortunately for Worcester, was also greatly interested in hospitals. He founded the London Smallpox Hospital and was a firm believer in the value of vaccination at a time when it was regarded with suspicion even in many medical quarters. Dr. McMenemey builds his story of the hospital mainly round a few attractive and forceful personalities. One of them, John Wall (1708-75), a surgeon to the hospital and a voluminous writer on medical subjects, founded the celebrated Royal Worcester Pottery as well as a large and prosperous family. (The fertility of the professional classes in the 18th and early 19th centuries was remarkable. Hastings was the sixth son of a parson, and families of a dozen or so are quite common in this history.) T. W. Walsh (never on the staff) left medicine to become "Stonehenge," one of the classical writers on sport, editor of the *Field*, and founder of the National Coursing and All England Lawn Tennis Clubs. Several members of the staff became Fellows of the Royal Society and had more than a local reputation.

The book has a special interest for members of the B.M.A., for the activities of its founder are conspicuous in the record, increasing our respect for the industry, diplomacy, and versatility of a remarkable man. Appointed apothecary (that is, house-surgeon) to the Infirmary at the age of 18, he left to become a distinguished student at Edinburgh, and returned to serve no less than 43 years as a surgeon. There were few activities in the city in which he did not play a leading part: he was an alderman, the founder of the Worcester Natural History Society, a foundation member of the British Association for the Advancement of Science, and last but not least the founder and for many years the most active member of the B.M.A. Dr. McMenemey amply justifies his statement that "he was destined to become the leading personality of his day in the profession of medicine and the most distinguished of Worcester's doctors."

We can confidently recommend this book to all interested in the early history of our Association and to all who can enjoy a spirited, well-written, and carefully documented account of the trials and triumphs of those who made the Worcester Royal Infirmary what it is. The book is well illustrated, and a word of praise is due to the publishers, who as a gesture to the Infirmary have charged their costs only.

ALFRED COX.

### EARLY AMBULATION

*Early Ambulation and Related Procedures in Surgical Management.* By Daniel J. Leithauser, M.D., F.A.C.S. (Pp. 232; illustrated. \$4.50.) Springfield: Charles C. Thomas. Oxford: Blackwell Scientific Publications, Ltd. 1946.

Dr. Leithauser writes in advocacy of early ambulation after operation. He points out that purgation and fluid deprivation in the pre-operative period, immobility immediately after the operation, and prolonged confinement to bed in the phase of convalescence are the causes of pulmonary and circulatory complications, bowel atony, muscle wasting, invalidism, and all those ills that go to make up what he terms the "laparotomy syndrome." All this had to be said, but it has been said before—often. The author's special contribution is that he gets patients to stand by the bedside as soon as they have recovered from the anaesthetic, and discharges them from hospital in a day or two. The author's background is difficult to assess. By his description of a hypothetical case treated on standard lines (pp. 34 and 35), and by the number of cases of parotitis he en-

countered, he seems to have been unfortunate in his early training and to neglect surgical progress in the rest of the world. Fig. 11, p. 84, shows a method of gastric suction that would prevent not merely ambulation but any movement, and make even respiration difficult. His attention was drawn to the benefits of early ambulation in 1938 by the rapid recovery of a patient who got out of bed a few hours after appendicectomy. He has practised the method since then, his experience consisting of 55% of appendicectomies and little major surgery. Those operated on for chronic appendicitis left hospital after an average stay of 1.9 days, and those operated on for acute after 2.19 days.

What is normal practice to-day, with which the claims of this book should be compared rather than with a hypothetical case? The patient is not purged, starved, or dehydrated before operation, but his deficiencies in blood, fluids, and nutrition are corrected, and he is taught breathing, leg, and abdominal exercises so that he can start these under supervision as soon as he recovers from the anaesthetic. He is encouraged to move as soon as he is conscious, and allowed to sit on the edge of his bed to empty his bladder and to walk to a commode when his bowels act. He is allowed to get across the room to a chair when he wishes to, and urged to do so after four days. He is kept in hospital till his wound is soundly healed—that is, from six to twenty days—but urged during that time to resume his normal activity. That first-day ambulation for everybody, instead of for those who wish it, is a better policy seems doubtful, and second-day discharge from hospital even more so.

If Dr. Leithauser's colleagues in his home town practice the kind of pre- and post-operative care he outlines in the first chapters, he has done them a signal service in writing this book. If any British surgeons still keep patients in bed for three weeks they ought to read it; they also ought to be shot. This is the work of an enthusiast who has seen the light and wants to tell the world. Good luck to him!

W. HENEAGE OGILVIE.

### VITAMINS AND HORMONES

*Vitamine, Hormone, Fermente.* By Dr. med. Rudolf Abderhalden. (Pp. 250. Swiss francs 14.50.) Basle: Benno Schwabe and Co. 1946.

*Chemistry of Vitamins and Hormones.* By S. Rangaswami, Ph.D., and Prof. T. R. Seshadri, Ph.D. (Pp. 329. 7 rupees, 8 annas.) Waltair, South India: Andhra University. 1946.

Vitamins and hormones claim our attention and challenge our intellect for three main reasons: they regulate general or special manifestations of all forms of life; their existence and distribution are of great significance in theories about the origin and chemical evolution of living organisms; and they provide us with therapeutic agents of great potency and precision. The books now under review, representative perhaps of the Germany of yesterday and the India of to-morrow, are good examples of the eagerness with which current biochemical information is being collected, arranged, and reported. Dr. Rudolf Abderhalden's book is the third edition of a work originally published in Halle in 1943. It is explicitly designed to give the medical practitioner the acknowledged facts about the physiology of the vitamins, hormones, and enzymes, omitting all material that is purely theoretical or speculative. The book is carefully planned and arranged, as might be expected from the author, who bears the name of a family renowned in biochemistry. The treatment of the subject is almost lexicographic. The author devotes a section to each of the principal vitamins and hormones, setting out the properties, chemical constitution, methods of estimation, natural distribution, physiology, clinical applications, and medicinal sources. He summarizes everything pertinent in a lucid and tidy way, though the general reader, misled possibly by the easy exposition into thinking that biochemistry is a simple discipline, will soon be chastened by the structural formulae, one of which occupies half a page. Of interest are the lists of proprietary vitamin and hormone preparations available (presumably) in Germany during the war, and issued by the firms of Wander, I. G. Farben, and Merck. By the section on ferments is brief and sketchy, apart from pages devoted to the "Abwerproteinase" reaction worked out by Emil Abderhalden and his colleagues based on the theory that functional diastases...

tissue is associated with the release of the characteristic tissue proteins into the general circulation. These stimulate the liver, which responds by elaborating corresponding proteinases, which are excreted in the urine and may be used in the diagnosis of endocrine diseases. A similar type of urinary proteinase is claimed to occur when malignant growths are present, and may be of value in diagnosis.

The book by Dr. Rangaswami and Prof. Seshadri, both of Andhra University, is a conscientious review of the progress of vitamin and hormone chemistry during the past fifteen or twenty years. The authors take little for granted and illustrate all important chemical reactions by the appropriate structural formulae. The book abounds in flow-reaction diagrams, carefully drawn, clearly printed, and not crowded on the page. The text is written in a direct and simple style, and, while there is nothing unusual in the plan of presentation, an unusual amount of information has been collected. The book will be useful to the student of organic chemistry as well as to the biochemist. European and American readers may regret the omission of any tabulations of the vitamin content of the principal Indian foodstuffs, and such might provide an instructive appendix to a subsequent edition of this useful book.

W. R. FEARON.

### POISONS IN FIRST AID

*Poisons, Their Properties, Chemical Identification, Symptoms, and Emergency Treatments.* By Vincent J. Brookes and Hubert N. Alyea. (Pp. 209. 16s. 6d.) New York: D. Van Nostrand Company, Inc. (250 Fourth Avenue).

The authors of this book, which is intended for the use of the police and those who practise first aid, are a sergeant of police and an associate professor of chemistry. They begin with an account of tests, symptoms, and treatment. Under the latter they discuss the use of emetics but intentionally omit mention of gastric lavage. The main section is a list of poisons arranged alphabetically with formulae, description, uses, tests, symptoms, and treatment. Each entry is intended to be complete, which involves repetition of such phrases as "Summon a physician," but this arrangement is useful for quick reference provided that the poison taken is suspected. The tests given are for application to the remains of the substance or to a first vomit; they are not intended for traces. A table briefly summarizes the information. The authors then devote a section to industrial hazards, also arranged alphabetically, which includes a table of the number of parts per million of volatile substances and dusts in the atmosphere permitted in New Jersey. The division into these sections hardly seems necessary, since each is in alphabetical order and there is a good index. Chapter 6 is on foods, plants, snakes, and spiders, and chapter 7 on special techniques such as artificial respiration and the administration of oxygen. The appendix includes a glossary and tables of reagents and weights and measures. The illustrations are excellent, though perhaps that of a poisonous snake is too lurid.

Some of the omissions seem strange to us, though differences in American practice may account for them—for instance, neither weed killer nor sheep dip is mentioned under "arsenic." The authors do not discuss salicylic acid and aspirin, nor do they refer to the use of calcium compounds such as chalk in the treatment for oxalic acid poisoning. However, on the whole they present the material appropriately to the readers for whom the book is intended. No medical man will find it useful as a textbook, but for rapid reference, especially by those in contact with industry, it is well arranged and comprehensive.

J. H. RYFFEL.

*A Synopsis of Orthopaedic Surgery* (London: H. K. Lewis; 15s.), by A. David Le Vay, M.S., F.R.C.S., summarizes the literature to help students, including postgraduates, to prepare for examinations. We need not therefore expect it to be "readable," and indeed it is sometimes irritating. Readers will find it more useful for learning the facts of orthopaedic pathology and diagnosis than for its account of treatment, where there is some lack in critical assessment of method—for example, in the description of the now generally discarded lateral bloody approach to the hip-joint. Nevertheless Mr. Le Vay's book will be useful to a student for revision if he already has a knowledge of the subject based upon clinical study, and it should stimulate him to search other sources. For this purpose it would be improved if each section included selected references to the modern literature.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Escape to Live.* By Wing Commander Edward Howell, O.B.E., D.F.C. (Pp. 230. 8s. 6d.) London: Longmans, Green and Co 1947.

The commander of a fighter squadron describes the 1941 Middle East campaigns, his capture, and ultimate escape.

*An Introduction to Gastro-Enterology.* By James D. Lickley, M.D. (Pp. 143. 8s. 6d.) London: Simpkin Marshall (1941), Ltd 1947.

A manual for medical students and house-men on the diagnosis and treatment of disorders of the alimentary tract.

*Atlas of Bacteriology.* By R. Cranston Low, M.D., F.R.C.P.Ed., F.R.S.Ed., and T. C. Dodds, F.I.M.L.T., F.I.B.P., F.R.P.S. (168 plates. 32s. 6d.) Edinburgh: E. and S. Livingstone. 1947.

Coloured plates depicting cultures and photomicrographs of micro-organisms.

*An Introduction to Dermatology.* Formerly by Sir Norman Walker, F.R.C.P., and G. H. Percival, M.D., Ph.D., F.R.C.P.E., D.P.H. 11th ed. by G. H. Percival. (Pp. 349. 35s.) Edinburgh: E. and S. Livingstone. 1947.

This edition has been rewritten; includes many coloured plates.

*Studies of the Renal Circulation.* By Joseph Trueta, M.D., et al. From the Nuffield Institute for Medical Research, Oxford. (Pp. 187. 25s.) Oxford: Blackwell Scientific Publications. 1947.

Experimental investigations into the renal and intrarenal circulations.

*A Guide to Anatomy.* By E. D. Ewart. 6th ed. (Pp. 318. 25s.) London: H. K. Lewis. 1947.

An illustrated manual of anatomy intended for students of physiotherapy.

*Le Vie dell'Errore Clinico.* By Ettore Debenediti. (Pp. 160. No price.) Turin: Edizioni Minerva Medica S.A. 1947.

A general account of errors in clinical diagnosis.

*Medicine.* By A. E. Clark-Kennedy, M.D., F.R.C.P. Vol. 1. "The Patient and His Disease." (Pp. 383. 20s.) Edinburgh: E. and S. Livingstone. 1947.

The first volume of a work intended to correlate the facts of medicine rather than to instruct in its various methods.

*Modern Dermatology and Syphilology.* By S. W. Becker, M.D., and M. E. Obermayer, M.D. 2nd ed. (Pp. 1,017. £5 10s.) London: J. B. Lippincott Company. 1947.

Includes new material on vitamin therapy, penicillin, and tests for syphilis.

*Conduction Anesthesia.* Edited by J. L. Southworth, M.D., and R. A. Hingson, M.D. (Pp. 981. £5 10s.) London: J. B. Lippincott Company. 1946.

An account of local analgesia by means of nerve block, refrigeration, and local infiltration, as well as spinal analgesia.

*Précis de Physiologie.* By L.-C. Soula. (Pp. 1,085. 1,450 francs.) Paris: Masson et Cie. 1947.

A textbook of physiology.

*Précis de Dermatologie.* By A. Civatte. 5th ed. (Pp. 1,152. 1,700 francs.) Paris: Masson et Cie. 1947.

An outline of dermatology for the student and practitioner.

*Rheumatism.* By Lord Horder. 5th ed. (Pp. 61. 2s. 6d.) London: H. K. Lewis. 1947.

Notes on the causes, incidence, and prevention of rheumatism, with a plan for national action.

*Le Problème du Cancer et Son Evolution Recente.* By Michael Mosinger. (Pp. 664. 1,000 francs.) Paris: Masson et Cie. 1946.

A study of the aetiology and pathology of neoplasms.

*L'Hyperinsulinie.* By Marcel Sendrail. (Pp. 247. 500 francs.) Paris: Masson et Cie. 1947.

A monograph on clinical and experimental hyperinsulinism.

## NEUROSIS AND INDUSTRY

No time could be more appropriate than the present for any contribution towards increasing the productivity of our available manpower. It is common to think that this task is one to be solved mainly by the creation of stimulants or incentives—the stick or the carrot—to higher levels of output, and that the most effective techniques for this purpose can be evolved by those experienced in industrial management. The contradictory views expressed in the correspondence columns of the Press in the last few months, however, have made it apparent that little scientific progress has been achieved in the task of finding those positive influences which might raise the level of output. On the other hand, it has become increasingly evident in recent years that a serious loss of productivity is due to the persistence of, and possibly an increase in, negative influences, or factors which prevent individuals from maintaining their normal rate of output—e.g., those which lead to absence from work.

During the war, when evidence from many sources indicated that neurotic illness was one of the common causes of absence from work, the Industrial Health Research Board sponsored a study on "the true incidence of neurosis among factory workers and of its effects on production, and for an appraisal of the factors predisposing to such illness." The report of the study,<sup>1</sup> which was carried out by Dr. Russell Fraser and collaborators, certainly answers the questions on the extent of neurosis and its effects on production; and even if, as is pointed out, the results cannot be applicable with certainty to a wider field and to peacetime conditions, the findings have a familiar ring in relation to the industrial scene to-day, and they are too important to be ignored.

Fraser's careful investigations covered a random sample of over 3,000 male and female workers from a population of 30,000 employed in thirteen light and medium engineering factories. The main results are that neurotic illness caused between a quarter and a third of all absence from work due to illness and that neurosis was responsible for the loss of 1.09% of the men's possible working days and of 2.4% of the women's—a loss equivalent to an annual absence of three working days by every man studied and of six days by every woman. The latter figures may not at first sight sound serious, but what is more disturbing is that 10% (9.1% of the men and 13% of the women) had suffered from definite and disabling neurotic illness, and a further

20% (19.2% of the men and 23% of the women) from minor forms of neurosis—e.g., psychosomatic illness, some abnormalities of personality which indicated reduced mental health—during the six months before examination. These figures are much more serious in their implications when it is borne in mind that the investigators only recorded illness leading to absence. The milder interferences cannot but have been there with quite unknown effects on output either by direct loss in work done or by indirect effects in inefficient work.

It is stated in the report that "it was not the purpose, nor the outcome, of this inquiry to show how neurotic illness can best be alleviated. It is, however, implicit in many of the findings that measures tantamount to good welfare and social work, both within and outside the factory, would be beneficial in alleviating and preventing neurosis, as would also, presumably, more extensive facilities for the medical treatment of neurotic illness than were available during the war." After the incidence of neurosis was determined a search was made for evidence of any association between the incidence of neurosis and the environment of the subjects—not that it was assumed that any particular environmental factor associated with more than average neurosis was a cause of this increase in neurosis, but rather that the demonstration of a significant association with any particular factor is informative from several points of view. The circumstances associated with more than the usual incidence of neurosis include many that would be expected—e.g., excessive hours of work, restricted social contacts, recreation, or leisure interests, work unsatisfying or requiring skill inappropriate to the worker's intelligence, monotonous work programmes, and certain types of work. Particularly noteworthy are the statements that most commonly the circumstances outside the factory which were associated with a high incidence of neurosis are "characterized by unsatisfactory human relationships. The more obviously unsatisfactory the human relationships the closer the association. . . . Further, since unsatisfactory human relationships outside the factory are associated with a high incidence of neurosis, it is probable that the nature of the human environment within the factory may influence the amount of neurosis." It is also of fundamental importance to note that in the factories studied neurosis was as frequent among those on the more skilled as among those on the less skilled jobs, and as frequent among those usually receiving the highest range of earnings as among those usually earning less. Further, it was almost as frequent among foremen as among workers. These latter findings suggest that the effects of neurosis on production may be far greater than can be reckoned by objective indices such as absence. It is obvious that the quality of human relations within the working group is very heavily affected by the quality of the leadership available, which in turn must be adversely affected by an appreciable incidence of neurosis shown to exist at least within the lower levels of management.

The outstanding implication of this important report is the urgent need for further research in this field. It was remarked earlier that the doctor could contribute to the present crisis by helping to keep absence from work at a

with the infectivity, morbidity, and mortality of familiar diseases such as measles and whooping-cough.

### NEW POLIOMYELITIS MEASURES

The importance of early diagnosis in cases of acute poliomyelitis and polio-encephalitis has been repeatedly stressed and is obvious. With no more than some hundreds of cases in this country in each year since 1938 few doctors have had the opportunity of seeing cases at the early paralytic stage. To make good this fortunate lack of experience the Ministry of Health has taken the initiative and sponsored the shooting, which began this week, of a short film on the early diagnosis of poliomyelitis. It is hoped that the film will be shown to medical audiences about a fortnight hence. The British Medical Association has agreed to assist the Central Office of Information in distributing copies of the film and in arranging for it to be shown to doctors. The Secretaries of Divisions or Branches who would like the film to be seen in their areas should communicate directly with the Secretary of the B.M.A. Projectors and operators can be made available by the regional offices of the C.O.I.

On the question of treatment there have been two interesting developments in the London area this week. Consultations have been held between representatives of the L.C.C. and the London teaching hospitals. During the week ending Aug. 9, 106 cases were admitted to hospitals in the L.C.C. area, as against 55 in the previous week. The London teaching hospitals have now agreed to set up as soon as possible special units for the treatment of cases of poliomyelitis in the acute stage. The beds set aside for this purpose will be allocated through the Emergency Bed Service (Telephone Clerkenwell 6571).

The Emergency Bed Service has also agreed, during the present emergency, to extend its services in connexion with the distribution of mechanical respirators outside the immediate London area. No matter how early the diagnosis is made, a proportion of these cases will require treatment by means of mechanical respirators. The E.B.S. has a record of the location of all the "iron lungs" available in and around the London area and is prepared to arrange for these respirators to be moved promptly from hospitals where they are not in use to hospitals which need them.

### LIMITS OF CERTIFICATION

The doctor's first duty is to his patient. In these days it seems necessary to repeat this truism over and over again because there are so many forces at work trying to upset this traditional duty of the medical man who treats the individual. The filling in of certificates has become an occupational disease in the medical profession, and in our issue of Aug. 2 (p. 187) Dr. Desmond Curran drew attention to an unfortunate example of this minor medical malady. In the same issue we recorded the view put to the A.R.M. by Dr. J. H. P. Giff (*Supplement*, p. 34) that the time had come "to make a stand against this unnecessary and aggravating certification." Dr. Giff was concerned with certificates for surgical corsets. Dr. Curran was dealing with the Civil Service Commissioners, who asked for a full and detailed report which "would place them in a better position to decide on each candidate." Dr. Curran, in our view quite properly, informed the Commissioners that he would state only his opinion whether there was any medical reason why a man should or should not be accepted. He makes the point that a candidate will express himself freely to the doctor if he knows that what he says will be regarded as confidential: this is of particular importance in psychiatric cases. There is, too, the possibility that a candidate

will take for granted that anything he says will be regarded as confidential and will assume, as he has every right to assume, that what he says to his doctor will not "be put away in a Government file and perhaps seen by numbers of laymen." That the Civil Service Commissioners did not perhaps feel too happy about the matter is shown in their request to Dr. Curran that he should regard as strictly confidential "the information concerning their practice." With more and more people being caught up in the State machine this question of certification will become more and more important. And as the medical profession comes more under the control of the State the individual doctor will find it increasingly difficult to perform his duty to the individual patient. Dr. Curran asks for "an authoritative ruling on the limits of certification intended for the use of lay bodies." Just who should or would make this a ruling is not clear, but at least a medical man asked to provide such a certificate should make quite sure that the full consent of the person examined is obtained before any certificate or report is submitted. Dr. Edward Glover in the correspondence columns this week (p. 269) suggests that the post-war period may be a silly season for psychology. He may or may not be right, but it is certainly a silly season for certificates.

### ERGOTAMINE IN THE TREATMENT OF PRURITUS

One of the methods used for the treatment of pruritus is the administration of ergotamine tartrate. Nevertheless it may cause gangrene, as a recent paper by Kenney<sup>1</sup> shows. Ergotamine tartrate constricts the peripheral vessels and reduces the extent of arterial pulsation. Presumably it is the diminution of the peripheral blood supply that relieves the pruritus, and if the diminution goes too far the danger of gangrene arises.

Lichtman<sup>2</sup> in 1931 began the use of ergotamine ("gynergen") for pruritus, and described 4 cases (2 of renal and 2 of hepatic origin). He gave 1 mg. three times a day by mouth, and stopped the drug as soon as relief was obtained; the results were excellent. Snell and Keyes described a series of 12 cases, and noted that pruritus occurred in 60% of patients with gall stones; they gave ergotamine tartrate by mouth and also by intramuscular injection. Later workers, however, recorded ill-effects. Yater and Cahill<sup>3</sup> had a patient whose legs had to be amputated because of gangrene induced by ergotamine. Gould, Price, and Ginsburg<sup>4</sup> gave 0.25 mg. of ergotamine subcutaneously daily for four days. After the second injection pain and coldness developed in the extremities, followed by cyanosis and impaired sensation. This patient died four days after the initial dose of ergotamine tartrate. These cases are of course exceptional, and as a rule when coldness and cyanosis appear they cease when the drug is discontinued. Further treatment includes papaverine hydrochloride (20-30 mg.) intravenously or orally as a vascular spasmolytic. Ergotamine tartrate is contraindicated in the presence of sepsis or of cardiovascular disease.

Since such serious risks attend the use of ergotamine for the treatment of pruritus, it seems likely that it will soon be replaced by the new antihistamine drugs, such as "anthisan" or "neoantergan,"<sup>5</sup> which are effective at least when the pruritus is associated with urticaria. Extensive pharmacological investigation has revealed no serious toxic effects from the use of these substances.

## CONTACT LENSES

BY

C. G. KAY SHARP, M.D.

The possibilities of contact lenses have been appreciated since 1827, but it was not until von Rohr, of Jena, developed the glass contact lens that they became available for general application. In this country Dr. Josef Dallos, of Budapest, in more recent times, has made a material contribution to the development of contact lenses. In general, much secrecy has surrounded the manufacture of contact lenses, and little has been written about them in the medical press. Contact lenses are now an established treatment for definite clinical conditions. They are becoming available in increasing quantities, but the demand far exceeds the supply. At present this is mainly due to the deficiency in the number of trained technicians, and although the position is improving there is still a delay of three to four months before supply.

## Varieties

Contact lenses are transparent optical appliances so made that they fit closely over the conjunctiva covering the sclera but provide for a small clearance over the cornea. The earlier contact lenses were, and in some of the principal ophthalmic centres still are, made of glass, but during the late war intensive development took place in the provision of contact lenses made of plastic material.

This material has certain advantages over the glass product: (1) It has more resiliency and elasticity—the thin scleral portion of the contact lens can the more easily adapt itself to any disparity between its curvature and the curvature of the sclera. (2) It is clearer than glass. (3) It is unbreakable, except with gross misuse. (4) It is about one-ninth the weight of glass, thus reducing ocular fatigue to a minimum. (5) It is more resistant to the action of tears; consequently plastic contact lenses require to be repolished less frequently than glass lenses.

For general purposes it may be accepted that contact lenses are made either of glass or of plastic material. The methods by which they are produced are briefly: (a) blown glass, as in the production of artificial eyes; (b) glass ground from solid glass; (c) glass moulded to the shape of the eye: an impression of the eye is taken as for a denture; (d) plastic contact lenses fitted to the eye by the ophthalmic surgeon, the final prescription incorporating such adjustments as he may find to be necessary and also the lens power required to correct the residual axial ametropia. All these methods are in use at the present time. Whether or not one of them will eventually prove to have sufficient advantages to justify its adoption as the method of choice remains to be seen. Enough data are not yet available, especially in regard to the use of plastic material, but my own experience, gained in ophthalmic practice and in the Contact Lens Centre at the Royal Eye Hospital, London, tends to show that the advantage lies with plastic material. In all types of lenses the corneal segment of a contact lens is in the initial stages plano, and the additional spherical power, plus or minus, is worked on the anterior surface of the segment.

## Advantages and Limitations

One of the results of placing a contact lens on the eye is that the curvature of the cornea is supplanted optically by the spherical curvature of the corneal segment of the contact lens. The presence of a well-fitting contact lens may at first be appreciated as is that of a wrist watch, or a ring on the finger, for the first time, but very quickly the sensation disappears, and there is no difference of sensation whether the contact lens is in position or not.

Patients are not necessarily able to discard their spectacles entirely when adopting contact lenses. Each case has to be considered on its merits by the ophthalmic surgeon; but, generally speaking, contact lenses are an important and useful addition.

The length of time these lenses may be worn varies considerably. Some patients may wear them all day, but much depends on their neuro-vascular condition and on the condition

of the conjunctiva, and as a general rule it is considered satisfactory if contact lenses can be worn continuously with comfort for four hours. This period is sufficient for most special purposes—e.g., dances, theatres, cinemas, public functions, sports, and flying duties. Plastic contact lenses are especially valuable in sports and in flying duties on account of their safety and light weight. A greater number of hours' wearing time per day may be obtained by staggering the periods of wearing.

The hypermetrope should see as well with contact lenses as with spectacles, but in the higher powers may at first be conscious of a slightly smaller retinal image. The myope, especially in the higher powers, should see better with contact lenses than with spectacles on account of the larger retinal image.

## Indications

Undoubtedly, when the supply of contact lenses permits, the greatest number will be used for cosmetic reasons. The young adolescent who normally wears thick lenses in spectacles may justifiably be recommended to adopt contact lenses for special purposes, whether social, professional, or sports. The presbyope may be advised to wear contact lenses, if desired, but for optical reasons bifocal lenses cannot be prescribed: he must decide whether correction of the ametropia for distant vision or for near vision would be the more useful.

There are indications for contact lenses in many pathological conditions, as an aid to plastic surgery in the prevention of symblepharon, and in the location of intraocular foreign bodies. In incomplete closure of the eyelids, ectropion, entropion, trichiasis, and proptosis contact lenses are prescribed for protective purposes, as they afford immunity from corneal irritation and ultimate ulceration. They are useful in preventing troublesome sequelae in sclerosis of the conjunctiva following trachoma and burns of the eye.

The most remarkable results from the use of contact lenses are achieved in keratoconus, nebulae, and leucomata, and in mustard-gas keratitis. In all these conditions the anterior surface of the cornea presents gross irregularity which cannot be corrected with spectacles. The contact lens replaces this irregular surface, optically, with the regular spherical surface of the corneal segment, on which is worked the spherical correction of the axial ametropia. Consequently, if there is any clear cornea available in the pupillary area, or after an optical iridectomy, contact lenses permit a considerable improvement in visual acuity.

I know of patients registered as blind under the Blind Persons Act who have obtained little or no improvement in visual acuity with spectacles, but whose vision has improved from 3/60 to 6/12 with contact lenses. Instead of being registered as blind persons they have legally been able to obtain a licence to drive a car.

In albinism and aniridia much relief may be obtained from the distressing photosensitivity, especially if an artificial iris be added to the corneal segment. In neuroparalytic keratitis contact lenses provide all the advantages of a tarsorrhaphy with none of its disfigurement. Surgical treatment of the trigeminal nerve or gasserian ganglion is an indication for the provision of contact lenses in anticipation and prevention of a neuroparalytic keratitis. Contact lenses specially fitted with metallic inclusions—e.g., metal bead at 3, 6, 9, and 12 o'clock, or a metal ring at the junction of the scleral and corneal segments—are used in the location of intraocular foreign bodies.

## Fitting

The determining factor both in glass and in plastic contact lenses appears to be the careful fitting of the contact lenses by the ophthalmic surgeon. Contact lenses manufactured from a mould of the eye have many advocates, but the errors which may arise from taking a mould are by no means negligible, and the procedure is an unnecessarily unpleasant one. It seems to have no advantages over the simpler method of applying plastic contact lenses, with such adjustments as may be apparent to the ophthalmic surgeon when fitting them.

The contact lens consists of two segments—the scleral and the corneal—each having a different radius of curvature. The scleral segment fits snugly on the conjunctiva covering the

sclera. The corneal segment has a slightly smaller radius of curvature than that of the cornea, thus providing a small space between the cornea and the contact lens. This space is filled with a buffer solution isotonic with the tears. The pH of the buffer solution prescribed varies with the pH of the tears. An exception to the rule that there should be clearance of the cornea may be made in conical cornea, where a corneal segment may be prescribed in close contact with the corneal cone, so preventing progression and even slightly reducing the effect of the cone.

The contact lens should not be so firmly in contact as to constrict the conjunctival vessels, nor so loosely attached as to permit the buffer solution to escape, with the admission of air bubbles. It should not be so large as to interfere with the movements of the eyes nor so small as to be liable to be caught by the eyelids in movement. For these reasons mass production on standard measurements is impossible, each eye having its own individual requirements.

### DEGREES OF MURDER

Sir Norwood East, president of the Medico-Legal Society, read a paper on "Psychiatry and Degrees of Murder" before that body on June 26. His object was to show that while criminality in murder varies widely according to circumstances and personality any doctrinaire approach—any rigid fixity of degrees—would destroy the elasticity which prevails to-day and which on the whole secures in each case perhaps the closest approximation to justice that is reasonably possible.

During the period 1929-38 in Britain the death sentence was passed on 175 persons. Of these 81 were executed, while the sentence of 81 was commuted to penal servitude for life. (The few remaining cases were of sentences quashed on appeal, or dealt with abroad, or, under the Children and Young Persons Act, sentenced to be detained during the King's pleasure.) An examination of the figures for the last 67 years shows a proportionate increase in the number reprieved. In the period 1880-1929 the proportion reprieved was 44.16%, in the following ten years 50%.

As far back as 1866 a Royal Commission favoured the grading of murder, but although various Bills to that intent were introduced into Parliament they were all withdrawn or failed to get through. The difficulties of grading are very great. In grading by indictment, for example, a man might be charged with murder of the second class, whereas the course of the trial might show that it was a deliberate and brutal murder of the first class; but to alter the indictment would not be easy. Grading by the judge was not accepted by the Select Committee on Capital Punishment in 1930 because it would leave too much to the temperament and general attitude of the judge concerned. Grading by the jury was equally unacceptable to that committee because the evidence before the court is restricted to what is directly relevant to the proof of guilt and excludes many important matters which are rightly taken into account in the exercise of the prerogative of mercy. Even when the facts are clear the jury can hardly exercise equitably a grading discretion. Sir Norwood East instanced the usual prejudice against homosexual conduct, which, he suggested, might prevent a jury from assessing without bias the degree of guilt of a man who had killed his male paramour in an outburst of jealousy. There remains grading by the Home Secretary, which in practice does, generally speaking, meet the want of classification.

### Findings of the Psychiatrist

The findings of the clinician, toxicologist, pathologist, and psychiatrist, said Sir Norwood East, might all assist in grading murder. The psychiatrist would note the effects on behaviour of various degrees of intelligence and will-power, emotion and temperament, character and personality, and abnormal mental states, and would take cognizance of social, ethical, economic, and other factors, thus demanding a wide approach. Many homicidal crimes were associated with emotional stress. The prevailing psychological atmosphere at the trial of the survivor of a suicide pact or of a deserted woman who had committed infanticide might cause those taking part to temper their judge-

ment with sympathy and leniency, which might be all to the good, but it exemplified the importance of treating the offender individually.

Several degrees of murder were associated with insanity. Three gradations appeared when the crime was associated with mental defect—imbecility, feeble-mindedness, and moral defectiveness. The psychoneuroses and various states of psychopathic personality introduced degrees of culpability not amounting to legal irresponsibility but apparent to the psychiatrist. A jury was not equipped to assess minor degrees of mental abnormality.
